the best in my garden was not working so fast as others beside it. An examination was made, which revealed the fact that it had lost its queen by death and had reared a young one at a season when there were no drones. The young queen was a drone-breeder and useless; she was at once removed from the hive and killed, and a fertilised queen put in her place. Thus the hive was saved. Queens die when four years old, and therefore should not be kept longer than their third year. The aim of the bee-master should be to have as many young queens in his apiary as he conveniently can.

I remember buying a good hive some years ago. It was placed amongst other hives, and prospered as well as any of them for a while. I noticed that it loitered and fell behind the rest; on making an examination internally of this hive I found a drone comb in the centre of it, running from top to bottom and from side to side. This drone comb was the hindering cause. Working bees cannot be bred in drone comb, hence I cut half of the central drone comb out and fixed a piece of worker comb in its place, and thus gave the bees liberty to spread out their worker brood from comb to comb, and they were not slow in making use of the comb given to them, for it was speedily filled with brood, and the hive prospered fast enough afterwards. Examinations in August should be made to ascertain if hives have a sufficient number of combs filled or partially filled with brood to give them a strong population of young bees for winter and spring months. Hives well filled with young bees in autumn are placed on a high vantage ground for the year following. Hives containing six and seven sheets of healthy brood at the present time will contain five or six seams of healthy bees in March next, making them strong enough for any amount of work. Our letter of advice on feeding bees for any amount of work. Our letter of advice on feeding bees which lately appeared in the Journal made it clear that vigorous feeding in August caused bees to breed extensively.

By examining hives in the months of April, August, and September any bee-keeper may see whether they condense the internal moisture of hives or otherwise. If the inner surfaces of the hives are found covered with moisture he will wisely and naturally conclude that they are either badly ventilated or made of bad materials. Hives should be made of materials or so constructed that internal moisture never rests on their inner surfaces. Perfect ventilation of hives is a point of great importance in apiculture.

The robbing propensities of bees are strikingly manifested as soon as the flowers of the fields fail them. The industrial instincts

of bees never forsake them. When they cannot get food in the fields they become robbers and burglars, and enter the houses of their neighbours if not well guarded. Yesterday (August 20th) we turned up a large hive to examine it, and found it was being robbed. It had lost 10 or 15 ibs. of weight. We shut the door of this hive with a great many robbers inside, with a view to find out where the robbers came from. A handful of flour was procured, the door was opened and the robbers gushed out like a swarm, and many of them were marked and made dusty as millers by the flour and easily traced. They all came from one hive standing about 50 yards off in our garden. In such cases in which the bees of one hive are permitted to enter and carry off the stores of another hive, no measures can be adopted to prevent or stop this robbing but the removal of one of the hives to a distance of one or two miles for a while. At the end of the honey season, and while bees are being artificially fed, their doors should be contracted to enable them to prevent strange and robbing bees from entering their hives. Frequent and thorough internal examinations of hives in large apiaries we commend.—A. Pettigrew.

OUR LETTER BOX.

FOWLS INJURED (T. A. J.).—You have treated them quite correctly. Let their food at present be soft.

From observations taken near London during forty-three years, the average day temperature of the week is 68.3; and its night temperature 45.9°.

BULBS.

HE season for looking over the stock of bulbs and purchasing new ones is come round once more. It comes with the shortened days and people who live to hunt hate summer as the time which deprives them of their favourite

sport, and love winter as the season of thorough enjoyment. It can never be so with gardeners. If they have not the advantage of hothouses or greenhouses the depth of winter must be somewhat dreary,

and they must look forward to spring and summer as the most enjoyable seasons of the year. But with plenty of glass houses winter has almost more to interest than summer, inasmuch as plants grown in heat require more care and skill than plants grown out of doors. But the stroll on the velvet lawn is then over, and the blaze of summer flowers is gone, and the rich foliage of the subtropicals has departed, and the last Rose blown, and who can think of all this without a sigh? However, that time has not come yet. We are in September, and though there are scarcely any partridges, and the few there are get away in the corn which should have been cut weeks ago, we may yet enjoy some time of warm air, with now and then a chilly night and a somewhat wintry day. The walks will soon want sweeping almost daily, those beautiful Acacia and Plane trees shed their leaves so soon. Never mind, they are green enough still, and in that matter of dead leaves as in other things, "sufficient for the day is the evil thereof."

But the bulbs. How tempting they look in the seed shops as you pass by and see the boxes full of Hyacinths, and Crocuses, and Tulips, and Narcissuses! How pleasant it would be to go in and buy just what one chose of the fine round rich-looking bulbs of all sorts, "regardless of expense," and carry off the booty to the shades of the potting house for the future decoration of greenhouse and home; but it must not be. Bulbs are expensive, as they ought to be, when you think of the toil, and labour, and risk incurred in Holland and Belgium in their production; still we may look at them at least, for they are beautiful in themselves in an artistic point of view. People are apt to regard Onions as vulgar things, to be associated with dirty hands, and dropped h's, and bad smells; but to me a fine fat Spanish Onion, sleek and polished, beautifully tinted, and still more beautiful in form, is a thing to be much admired and not snubbed, as it usually is. I do not despise it when it comes to table, but I can hardly help half regretting that the only way we have of using a thing in itself so beautiful is by eating it. Such is the fate of

But all bulbs have a peculiar interest of their own, though they are so various in their flowers and in their mode of treatment. There is no arguing from what will suit one to what will suit another, like the boy who argued with his father that he would like, when he was grown up, to marry his dear, good, kind grandmother in this way: "You married my mother, why should not I marry your's?"

The same rule will not always apply to bulbs more than in marriage, except that generally most of them like plenty of water for their growing season, and then a dry, or moderately dry, time for their season of rest.

Bulbous flowers are so kind in coming early to remind us colder nights, which remind us that summer of approaching spring. Snowdrops grow wild plentifully is fast waning. Well, I have heard that in this county, so with the first perceptible lengthening of the days we can gather handfuls of them if wet ground is no objection. Children fill their hats with them, and you see them in every cottage window. They have no reason for having the same colour as their snowy surroundings like the Scotch hare, and the Arctic fox, and the Polar bear; but it seems appropriate that the first flower of spring should look snowy. And they linger on so long-long enough to greet their gorgeous-coloured friends the Crocuses. I pity those who do not like yellow flowers, they lose so much of the beauty of the spring garden—the yellow Wallflowers, and the yellow Pansies, and the yellow Alyssum, and above all the golden Crocus. Plant Crocuses by hundreds, and you will not be sorry in the bright sunshiny days of treacherous March, when the east wind is blowing bitterly one side and the sun shining brightly on the other side of the hedge. I have heard of a good clergyman who used to give a Crocus party just at the time when his garden was gay with their purple and gold. Certainly we have to pay for their beauty in the long tresses which are left behind; and even when these are twisted up, as farmers like to twist up their horses' tails, they look ugly enough; but notwithstanding that, they must be grown in sufficient quantities if possible to give sheets of gold in broad belts of their glittering cups or in complete circles, as most convenient. We have to pay for the glorious song of the thrush in the spring and autumn mornings by the loss of a certain amount of fruit, but his song is well worth the payment. I plant my Crocuses where the subtropicals are afterwards placed in summer; but many place them deep enough to grow the bedders over them, though this must somewhat interfere with the proper digging of the beds.

Another beautiful spring bulb, besides the Snowdrop, which grows wild in abundance, is the single Lent Lily or Daffodil. If Easter falls early enough in the year no flower is more useful for church decoration. It lasts well, and it can be used without stint, so that the decorations done with it always look particularly rich in colour. It likes the sunny side of the hill. Clumps of it which I have introduced into the garden have not done well, as I could not give them enough sun. It is best, however, to enjoy such wild beauties in their native haunts and to see them combined with the wild scenery of the rocky wood, or, where they frequently grow, in the more domesticated pasture of the sheltered orchard. Speaking of wild bulbs, there is one little beauty which grows in the sand on the coast of Devon, I will not say where for fear of destruction. have no doubt it is well known to many readers of this Journal. It is exceedingly rare, and therefore requires protection, for few can find such things without wishing to carry away a few to perish miserably in their distant gardens.

I am fond of trying rather out-of-the-way bulbs, such as NO. 1615.-VOL. LXIL, OLD SERIES.

NO. 962-VOL XXXVIL, NEW SERIES.

are not commonly grown. Many of them are very beautiful; for instance, Anomatheca cruenta, and Camassia seculenta, and Triteleia uniflora. There is something peculiarly interesting about plants which come up quickly, flower, and die speedily. The suddenness of the appearance and disappearance, the short life, and the beauty of the rigid form which most of them assume on account of the parallel veins which are common to all endogenous plants, give them an interest all their own. Anomatheca grows like a weed in Cornwall, and is beautiful in large patches; Camassia makes a good pot plant forced in early spring; and Triteleia is very hardy, and a great attraction on the rockery among other small but delicately marked flowers like itself. Schizostylis was not only useful in the days of spelling bees, but is an excellent flower for the autumn, coming with the Chrysanthemum and making a lovely nosegay in a large bunch by itself. This, too, quite revels in the Cornish climate, and will flower there the whole winter, but in this county it must be taken into the house.

Stove bulbs are often most beautiful. Take two only-and how much we owe to them for constant and fragrant flowers-Eucharis amazonica and Pancratium fragrans. The first associated with the Vallota, or Scarborough Lily, is one of the most beautiful plants imaginable. If the Lily has no scent it has great beauty to make up for it. It is a little wayward—that is to say, any old woman can grow it in her window, but some-how gardeners are often not half so successful in their greenhouses. It may be they treat it as if it required no treatment; certain it is in grand gardens it frequently does not look so well and healthy as in the parlour window. But why should not plants have a will of their own, and assert it too? Has it not been discovered that there is scarcely any difference between animal and vegetable life, and that it is quite impossible to say where one begins and the other ends. If chloroform makes the animal nonsentient it has the same effect on the Sensitive Plant, which loses its power of contraction under the influence of the anæsthetic just as the animal does, and recovers it when the influence is removed. Very well, in the same way perhaps the Vallota says to itself, "I like this good old soul who watches over me so tenderly in her pretty cottage window, and I will reward her with a flower;" but it does not care to be grand among other grandees. Seriously, there are plants which seem thus to accommodate themselves to humble life more than to the statelier life of the conservatory. A lady said quite seriously the other day she wished that dogs could go to church, she was sure they would be so much the better for it. There is nothing wrong in fancifully attributing to animals and plants a little more feeling than they really possess; but to read Sir John Lubbock's works makes one feel as if science was almost inclined to go in advance of the whim-sical notions of those who like to attribute sense and feeling to their home pets.

Well, bulbs are great pets of mine in the ground and out of it, and I am looking forward to taking a holiday some day among the bulb farms when I have no time to go further. The only difficulty in Holland might be the language, though the Dutchmen I have met with have spoken English as well as myself. It is not a language one would care to learn, even to talk to the labourers on the bulb farms, because it has no literature of its own. Flemish, to which it is nearly allied, is the most painful of languages to the ear, as everyone knows who has stayed to listen to the eloquent preachers in the beau-tiful churches of Antwerp. We let our Sunday school children buy bulbs for rather less than half price at this season, and then by-and-by in spring there is a little show in the coffee tavern, and prizes are given for the best Hyacinths and Tulips, not in money but in various useful articles. This has been a

great success.-A GLOUCESTERSHIRE PARSON.

OUTDOOR FIG CULTURE.

EXCEPTING in the south the Fig does not succeed as a standard. It appears to thrive best near the coast, which has been noted not only in this but other countries, and may be owing to the mildness, and partly to the genial humid atmosphere. It succeeds, however, very well inland if it be afforded a south aspect, and the soil is not too rich, which induces too luxuriant and soft growths for bringing fruit to maturity. In almost every instance where the Fig is found to succeed the soil is calcareous and shallow, resting frequently on chalk or a gravelly subsoil. I have seen very excellent Figs produced by trees that had not more than 3 feet width of border to grow in,

in front being a gravel path that prevented the extension outwards of the roots; and against a building with a south aspect trees produced fine fruit though they were planted in a payed yard. In both instances thorough drainage was provided, and the space for the growths was not nearly so restricted as frequently is the case with trees planted in wide borders of rich soil and trained to garden walls. They required very little attention in pruning and training, except in securing the growths to the wall and thinning them out where too crowded in summer. In most instances Fig trees in gardens grow too luxuriantly, producing indifferent crops; this may be rectified by root-pruning. For full-grown trees take out a trench 3 feet from the trees and as deep as the roots, making the trench about 2 feet wide and parallel with the wall. should be done before the leaves fall or at the close of September. If the border be well drained the trench may be filled with two-thirds loam and one-third chalk or old lime rubbish, placing at the bottom 9 inches of brickbats, and over it 3 inches of chalk or the riddlings of lime rubbish. The soil should be moderately dry and placed in the trench as firmly as possible. The surface soil in the space between the trench and the wall should be removed down to the roots, and the compost recommended for filling the trench should be worked in among the roots. If the weather be dry give a good watering and mulch with litter. The shoots should be thinned out so as to leave them about 9 inches apart, which will admit light and air to those retained and assist their ripening.

Instead of filling in the trench as above a single brick wall may be built without mortar against the face of the 3-feetwide border; this will restrict the roots considerably to the narrow border without confining them to it entirely, as they will find their way through the open brickwork, and when the trees are making too much wood a trench may be taken out just clear of the border wall, replacing the old soil or fresh as may be considered necessary.

In the case of trees that are planted in ordinary borders and that are unfruitful it is desirable to lift the trees to improve their condition. At 3 feet distance from the trees take out a trench and remove the soil from amongst the roots with a fork; lift the trees with as large a ball of roots as possible; cover the roots with mats to prevent their being injured by exposure to the air. Take out the soil to the depth of 36 inches, and 4 feet in width. At the bottom 3 feet from the wall must be a drain of 3-inch pipes having a suitable fall and outlet. In the case of a gravelly or otherwise naturally drained bottom the drain will not be necessary, whilst in the case of a heavy retentive subsoil it will be desirable to make a concrete bottom to prevent the roots going down. Place in 9 inches of rubble, 3 inches of chalk or lime rubbish, and form a firm border of two-thirds good loam and one-third chalk or old lime rubbish. In replanting the trees keep them a little raised above the general level of the border. Planting should be done when the leaves show indications of falling. In a border of the width and composition described above Fig trees will thrive much more satisfactorily than in one of greater width and formed of richer material. A 6-feet border is wide enough for Fig trees against garden walls, and it would be advantageous to confine them to it by a solid wall in front and a concreted bottom.

In ordinary well-drained fruit borders Fig trees usually produce satisfactory crops, the chief point to be attended to is keeping the shoots rather thin to admit light and air. If the trees grow too luxuriantly root-pruning must be practised, it being the most efficacious mode of inducing a fruitful con-Root-pruning should be performed in all instances as soon as the leaves commence falling. The only suitable form for the Fig against walls is the fan-shape, and if the trees have but one stem the energies of the plant will be concentrated on the head, whereas when the trees are allowed to produce suckers, as they do in abundance, they crowd and rob the parent stem. The great difficulty to contend against is overbarent stem. The great dimentify to rich a soil. As winter pruning can only be practised at the expense of the fruits, it is advisable to so train the trees that little winter pruning will be necessary. It is usual to prune in the spring, but it should be performed as soon as the leaves fall, merely removing any long bare branches so as to admit of well-furnished growths being trained in their place, but if summer disbudding has been attended to there will be little need of the knife.

Disbudding should commence when the shoots are about 3 inches long, reserving only the short-jointed in sufficient quantity for training-in. This disbudding will need to be practised up to August, therefore look over the trees frequently and remove all superfluous shoots, so that every leaf of the future year's bearing wood obtains free exposure to light. Pinch off the young shoots when they reach 4 to 6 inches in length. Trees that do not make more than a few inches of growth will not require pinching. In pinching it is only necessary to break off or remove the very tip of the shoot. To allow leaves to form and then remove them is a needless waste of the energies of the plant. Cut out some of the shoots altogether when they become too crowded, and lay-in others at full length, except where it is necessary to prune back to secure a fresh supply of young shoots from the lower part, seeking to have the lower part and centre of the trees equally furnished with bearing wood.

Except near the coast the trees require protection in winter, which should be afforded in December and removed in March. Mats, straw, or spruce branches may be employed. The safest plan is to loosen the branches from the wall, tie them together, and cover them with straw, and finally with mats; but with the wood short and well ripened the necessity for protection is not so great as when the growths are long and sappy.

No tree is so much benefited by top-dressings and copious supplies of water when swelling the fruit as the Fig. The topdressings and the waterings must, however, only be given to trees in a fruitful state that have not a tendency to grow too luxuriantly. The top-dressing is of two kinds—one given in autumn just before the leaves fall, removing the surface soil or summer mulching down to the roots, replacing it with turfy loam with a tenth of old mortar rubbish and a twentieth part of crushed bones, making the fresh material firm about the roots; and the other is giving a mulch over the roots of short decayed manure kept moist by watering as may be needful. In the warm parts of the south of England Figs may be grown and fruited to advantage in the form of low bushes or open standards, which form is the best that can be adopted for culture in the open, the trees being confined to single stems, requiring in the matter of pruning the least attention, as it is only necessary to occasionally thin out and shorten some of the branches. Even in the south the warmest situation must be chosen, the soil must not be too rich, and if it overlie chalk or a gravelly subsoil success will be more likely. Brown Turkey is the best variety for outdoor culture as bushes or standards; Brunswick, though not so prolific, is the best for cultivation against walls.—G. ABBEY.

GLADIOLI.

I AM afraid that this extraordinary season has to answer for the semi-failure of many flowers. On the 24th of August the hay was lying down in my parish soaked with rain, and no attempt has yet been made to cut the corn. The autumn show of cut flowers at the Crystal Palace was abandoned on account of the dearth of good autumn flowers this year. At the Exeter Show there was only one exhibitor in the open class for Gladioli and Roses, and these were by no means good; indeed the Roses were so bad that we did not deem them worthy of a prize. With regard to Gladioli, Mr. Dobree of Wellington showed some very good spikes, but his stand was uneven, and some of the spikes had very small flowers. He had some good enough to name after my wife. There were no Dahlias and no Hollyhocks; only one stand of herbaceous plants, which was so poor that no prize was adjudged. The Gladioli of Mr. Dobree, in spite of their uneven character, were the best flowers shown, and I have been requested to write a few lines on the culture of these flowers.

In a contemporary of yours a gentleman has been strongly urging the desirability of leaving the bulbs in the ground through the winter; in fact, to leave them like Liliums, and never disturb them except to renew the soil. This is what I may call startling advice, and is foreign to the experience of many large growers. I do not know whether I may be called a large grower or not, but I expend about £10 a year in Gladioli. I grow the plants in lines between dwarf Roses, and a very fine effect they produce. They bloom long after the first bloom of the Roses is over, and the stimulating mixture I give the Gladioli causes the Roses to make wood at the proper time; at least it would make them do so in any other soil than mine.

I never leave the corms in the ground during the winter.

My practice is to take them up as soon as the flower stalk is drying up, to leave them in the sun with the earth on, and then

to rub them dry and put them away till April. I have tried leaving a few out of doors during the winter, but these have gradually died away till I have only one left. A correspondent of mine who lives at Chipping Norton writes me that a friend of his has tried this practice with the most disastrous results. He left his corms in the ground last season and lost nearly every one of a collection of 250. His opinion is the same as mine as to the mode of treatment.

I hope this letter may induce some large grower to give us his experience. Gladioli are very expensive whether French or English. It is rather a stiff price to pay £10 to £15 a hundred for them, which is the price of the best English varieties, and then to lose them is a rather serious matter.

While speaking of these beautiful flowers I desire to say a few words as to their value for church decoration. Harvest festivals will soon be being held all through the country, and I know of nothing more suitable for altar vases than these handsome spikes; when mixed with corn, too, the effect is very good. Another flower most useful for these festivals is Tigridia Pavonia. These flowers when festooned with Wheat or Barley are very effective.

I wish someone would undertake an election of Gladioli. The number of varieties is so large that to take up a list like that in Mr. Kelway's catalogue and try to select a limited quantity from it is a most bewildering labour. Will any large grower give a list of the very best varieties? This with information respecting them and their culture would be valuable to others besides—John B. M. Camm.

FORCING STRAWBERRIES IN POTS.

I QUITE agree with your correspondent Mr. Brotherston, on page 184, that it is unwise to criticise those who differ from you in opinion or practice, particularly when the writer has not carefully studied the reasons on which that difference is based. It is evident from the style of Mr. Brotherston's remarks, either that he does not know the object of my notes, not having attentively read the articles which preceded them on the same subject, or that he has only perused them in a very careless manner. I think that every correspondent ought to be most careful not to put a wrong construction on the writings of another. If Mr. Brotherston will oblige me by kindly reading my notes on page 143, he cannot then fail to see that I am setting two systems of culture side by side in order to show the great advantage the one possesses over the other. The first system, in which the plants are separated from the parent plant and placed in small pots, being the one advocated by Mr. Ogle, which I entirely condemn; the other system—viz., that of layering into fruiting pots, being the one I adopt. Mr. Brotherston according to his own account does not force Strawberries, and as he admits he has never seen the first system (Mr. Ogle's) practised, I may fairly infer that he is not so competent to judge of the respective merits of plants grown under the two systems as those who practise them and have the plants standing side by side.

Plants grown in 3-inch pots in close frames might be considered by many growers fairly good, but when placed side by side with the plants grown under the other system we should not hesitate in calling them 'weak and puny.' It is only by comparison that we are able to judge of their respective merits. Now with regard to the washing of small pots I would ask, Is it customary amongst gardeners to use them dirty? If so, I suggest that the sooner the practice is discontinued the better. Lastly, as to removing plants from one pot to another. After long and careful observation I have arrived at the conclusion that they cannot be removed (from dirty pots especially) without the roots being more or less injured, consequently the plants receive a check which will be perceptible in proportion as they are of hardy or delicate constitution.—Wm. BARDNEY.

FRANCOA RAMOSA.

THIS plant is too rare now, and the request of "WYLD SAVAGE" for information respecting white decorative flowers for bouquets, chaplets, wreaths, &c., reminded me to send you a flower spray. The same circumstance reminded me to look for information respecting it. Imagine my surprise at not finding the least reference to it in plant catalogues to which I have access. So beautiful is it with me that several ladies and gentlemen have driven considerable distances to see it. It is now in flower, and forms a splendid contrast with Pelargoniums, Coleuses, Alpine Cyclamens (now flowering). Tuberous Begonias,

Lilies, Fuchsias, Gesneras, and Achimenes. I have, therefore, no hesitation in saying a word in favour of its extended cultivation, especially as that is so easy. It is a perennial, and propagaged by seeds, or divisions of the plant after flowering. It produces seed freely, but there will be a greater certainty of fructification under glass. It is not quite hardy, but I believe there are instances in favourable localities where it has tlowered freely outside. The leaves are also handsome, and contrast well with other greenhouse or window plants. I know of no other window plant so handsome, that will bear so much hardship, and with so little injurious results. With the aid of occasional applications of liquid manure it has flowered freely in a 5-inch pot, and when grown on slowly and not forced very few white flowers, excepting perhaps Orchids, remain so long in bloom.—W. J. M., Clonnel.

THE STAPLEFORD ROSES.

"HAVE you seen the Stapleford Roses?" "What do you think of Bennett's Roses?" are questions which I have been asked scores of times this season. "We hear a great deal of ' it was said over and over again; "but no one seems to care to exhibit them, and there is too much of the dark horse about them." To all this I was obliged to plead ignorance, for I had not seen them; and so about a month ago, on my way to Taunton. I determined to spend some time at Stapleford, examine the Roses for myself, and report progress. Happily in this dreary season I chose a very fine day; and so, although a considerable amount of mud was clinging to my boots, there was no moisture overhead, and I was enabled to inspect the experiments that are being carried on, notes on which I now give to the readers of the Journal.

Stapleford is not an easily accessible place. It is nine miles from Salisbury and four from Wilton. You can procure at the latter place a conveyance at the Pembroke Arms, and after a drive presenting no important features arrive at your destination. Mr. Bennett's house is a good, new, square-built farm residence, suggesting ideas of comfort and ease, but, with the exception of a greenbouse which catches the eye, not particu-

larly suggestive of floriculture.

Mr. Bennett's mind had long been exercised on the subject of Roses. He had grown them, had visited the French nurseries, had bought some from the French Rose-growers, and had been "done" by them, notably in the case of Duchess of Edinburgh (which had been substituted for Duchesse de Vallombrosa, the Rose he believed that he bad bought), and of which he destroyed five thousand when he found out the deceit practised on him. He has sent out, too. a Rose which has not received the recognition it deserves-Mabel Morrison, obtained at Leicester; but he had been impressed by the fact that artificial fecundation had not been resorted to, and that the beautiful Roses we now have are the result of chance hybridisation. I remember some years ago visiting old M. Margottin at Bourgla-Reine, and his telling me that he thought raisers had been depending too much on the Jacqueminot strain, and that he meant to return to some of the older Roses. For this purpose he had planted in a corner of his garden under cover a number of varieties for producing seed, but I am not certain whether he used artificial fecundation or whether he relied on natural causes; nothing came of it, and he has not sent out a good Rose since. Indeed the effects of artificial hybrid-ising are oftentimes disappointing. I have known it tried with Verbenas, where little success attended, and where all the efforts of the grower were distanced by a chance seedling that came up in a walk; and when such grand Roses as Marie Baumann, Gloire de Dijon, Maréchal Niel, and others are the results of chance hybridising it may well be asked, Can you better these? Perhaps not in their peculiar line; but that there are desiderata not yet obtained amongst Roses few are likely to question. A yellow Hybrid Perpetual is wanted, and also a dark crimson Tea. Moreover, many of the so-called Hybrid Perpetuals do not deserve the name. They give a quantity of bloom in the summer, and some send out flowering shoots from whence blooms may be obtained in autumn; but many never bloom a second time, while all of them send out flowerless shoots. What a Hybrid Perpetual ought to be is a Rose that, like the Tea Rose, is ever blooming and never producing a shoot that has not a flower bud: and a white H.P. the size and form of Charles Lefebvre or Marie Baumann would be hailed as a very Koh-i-noor amongst Roses.

It was, then, to attain these objects that Mr. Bennett set

how difficult it is to obtain in some seasons good healthy seed: so the mother plants he determined should be grown in pots and placed in the house when the time of Roses came on. varieties he selected as seed-bearing plants were chiefly Alba Rosea and President, and with these he crossed various Hybrid Perpetuals. I saw one plant of Alba Rosea, of which every flower had been crossed and each stem labelled with the variety employed to fertilise it, and every pip was full of good seed. These plants had been prepared for some time before they were used for seed. Thus every care has been taken to effect the desired end.

The soil on which Mr. Bennett grows his Roses, and where we were to look for the result of his experiment, is simply an open field of indifferent chalky soil—soil that will not grow Wheat, and only fairly Barley. The stock that he uses is the seedling Briar, and on this he grows not only his own seedlings but a large collection of named sorts. As might be expected, the flowers are not, any of them, such as we might see on the

Rose soils of Hertfordshire or Essex.

And now what has Mr. Bennett done? Has he obtained a yellow Perpetual? No; nor do I think as yet he is likely to do so. He had at the time I was there two on which he relied with hope. One was a seedling from Mabel Morrison crossed with Maréchal Niel, another Mabel Morrison crossed with Canari. These were not in flower: the buds were showing a little yellow tinge outside which looked promising, but I have since heard from him that neither of them has come yellow. although the latter has developed into a grand Rose. Mr. Bennett says, should this be the case that neither of them show signs of being yellow, it will be useless to persevere with Mabel Morrison as a seed plant for yellows, and I think it more likely to obtain a good yellow from a pink H.P. or even a darker Rose. Hence it may be concluded that a yellow Hybrid Per-

petual is still in the future.

Has he succeeded in obtaining a really crimson Tea? To this I say Yes, for that Duke of Connaught is such there can be no doubt. I do not agree with the too sanguine anticipation that "this will probably prove to be the finest crimson Rose in any section." It is not that, but it is a crimson Tea; its foliage is that of a Tea Rose, the bud is lengthened as in that class, and not a shoot even on the smallest plant but bears a flower. So much is this the case, and so continuous is the flowering, that a florist at Tottenham has purchased all that Mr. Bennett can supply for the purpose of cutting crimson Roses during the winter months. This Rose was in the hep on Christmas, 1877, so that as it has been increased by the thousand, it may well be imagined that it has not had much time to develope large flowers. It is a seedling from President crossed with Louis Van Houtte. Michael Saunders is another fine Rose, a seedling from President and M. Victor Verdier, with most decided Tea blood in it. It is large, of good form, colour a curious shade of pink, and with a most decided Tea perfume. This is the most likely Rose I saw to please exhibitors generally. Viscountess Falmouth, a cross between President and Moss Soupert et Notting, is a very extraordinary plant, and the flower is distinct in its colouring, delicate pink, the back of the petals darker, and very sweet scented. Beauty of Stapleford, a cross between Alba Rosea and Comtesse d'Oxford, has large flowers of good shape; outer petals pinkish rose, shading to a deep rose centre.

And now as to the question which has been asked me so often, and which, if I did not anticipate it, would be asked again after reading these notes, Are they good exhibition Roses? and has Mr. Bennett succeeded in his proposed attempt? The first question I do not feel quite entitled to answer. Those that I saw in bloom-Michael Saunders, Viscountess Falmouth, and Beauty of Stapleford, I imagine would, in a good Rose soil and after they have had a little fair play, prove good show Roses. I have always deprecated the notion of forming a decided opinion on new French Roses the first season, for this very reason—they get so backed and cut about and put through such unnatural courses that it is impossible to judge of them; and I say the same here. I think Mr. Bennett has made two mistakes. He sent out too many at once. We all know how few amongst the sixty or seventy Roses sent out by French nurserymen every year turn out worth keeping, even although they come from a dozen different raisers. We rarely retain above three or four of them in our gardens; and however good the Stapleford Roses may be, there is at once a doubt on the rosarian's mind—"All cannot surely be good; and if not, which am I to have?" I think it most likely that some of himself. He knew the fickle nature of our English climate, and | these will take their place on the exhibition table, as there is

a novelty of colouring in them which will form a good contrast to many kinds we already have. I am also certain that Mr. Bennett is on the right track. He was, I think, in too great a hurry to bring his Roses out. He would have given them a better chance had he waited another season, but I am sure such an intelligent method of procedure must produce good results. I have already mentioned a Rose which he hoped would come yellow, a cross between Mabel Morrison and Canari. He has been disappointed in its colour, but I have a letter from him in which he says that it is a most extraordinary flower and is most enthusiastic in its praises. He describes it as "exactly in the way of Baronne de Rothschild, much larger and much fuller, and quite distinct; a brighter salmon pink without the least shaling. Of the thousands that have bloomed here not one has at all come near this one. I have sent a messenger to London to try and get a faithful drawing taken

Such, then, are my views about these Roses. I am quite sure that they are a very interesting addition to our Roses, and that no lover of the flower will regret adding some of them at least to their gardens; and I think, too. that all resarians will wish Mr. Bennett success in his painstaking endeavour to impart novelty to our Rose lists. We seem in some classes to have reached a point beyond which it is hopeless to try to go; but there are others, and those on which Mr. Bennett is at work, which will reward him and add fresh enjoyment to the lovers of the queen of flowers.—D., Deal.

GRAPES WITHOUT FIRE HEAT.

In the report of the Glamorganshire Show it is stated that Mr. J. Muir was awarded the second prize for Black Ham-burgh Grapes "ripened without fire heat." The sentence quoted appears to me to require a little explanation. I have seen houses of Black Hamburgh Grapes in the south of London this year in some of which the utmost advantage has been taken of sun heat when there has been any, and yet the Grapes are only just commencing to colour, and will not ripen unless we have five or six weeks of uninterrupted sunny weather. The vineries to which I refer have no heating apparatus connected with them. The nonripening of the Grapes is causing disappointment, which has not been lessened by the record of Mr. Muir's success. It appears to me important to know if the Vines at Margam Park which have produced ripe Grapes without fire heat in the autuan, were started with the aid of fire heat in the spring. If this was not the case Mr. Muir must either have a very early variety of the Black Hamburgh, or the climate of Glamorganshire is especially salubrious and far exceeding that of most districts of the country. Black Hamburgh Grapes can be ripened "without fire heat" in ordinary seasons, but the instance referred to is the only one which I have noticed of their having ripened wholly with the aid of sun heat this year.—A. C. M.

DESFONTAINIA SPINOSA.

THE beauty of this evergreen Chilian shrub when in flower is so great as to induce a feeling of regret that any misconception of its real value as a decorative plant should exist. Twenty-four years ago it had been planted out in an open border at Exeter, and proved very free-flowering and quite hardy. Two years ago, at this season of the year, I saw nu-merous groups and single specimens of it thoroughly esta-blished in the gardens of Devonshire and Cornwall, all of them thickly clothed with deep green, glossy, Holly-like foliage, and with many of the tubular pendant flowers still in the full brilliancy of their mingled colours of scarlet and yellow, to which the foliage forms such an admirable foil. In height they ranged from a yard to 5 feet with a somewhat formal and erect habit of growth, which rendered them more pleasing to the eye in groups than when planted singly. Very lately I saw a small plant that had been growing in the open garden at Buxted Park for some years and is quite hardy. This has the ordinary rigid growth, but in the garden at Brambletye there is one well established in a border that has long shoots branched and spreading, and foliage more sparsely set with marginal spines than the ordinary type. Other plants of it at Brambletye have developed individual peculiarities. All of them, however, passed unscathed through the severities of last winter, which, I think, affords conclusive proof that we have here not a mere greenhouse shrub as was erroneously supposed, but an addition to our collection of choice hardy shrubs that will much enhance the beauty of mixed groups, as well as afford us a distinct and novel feature when grouped alone, in the southern counties at any rate. Mr. Jenks informs me that its flowers emit a peculiar and agreeable perfume, of which important property I had not hitherto been aware, and am desirous of learning if it has been commonly observed, or is peculiar to the Brambletye specimens alone.—E. Luckhurst.

COTTAGE HORTICULTURAL SOCIETIES.

YARDLEY WOOD SHOW.

SOME months back an interesting correspondence was carried on in your Journal, the subject being "Cottagers' Horticultural Societies." A certain "YORKSHIRE CURATE" gave your readers the pessimists' view on the subject. From that moment I determined to establish such a society here, and hope that you will allow me space to report upon our first Exhibition which was held on September 8rd. I enclose you our schedule of prizes and rules of

I quite agree with the "YORKSHIRE CURATE" that there is much trouble and annoyance to be experienced by those who have to start and manage these exhibitions, but surely the result repays us all such trouble a thousand times. The social and moral character of one's parish is marvellously improved in spite of the east wind blown by the very few really disappointed exhibitors. But I must at once come to results. This is a small country parish without gentry, seven hundred inhabitants, yet we had a subscrip-tion list of about £18; several friends outside the parish of course We voted about £15 for prizes, and advertised freely. I wrote letters to friends, amateurs and nurserymen. Mr. Charles Turner, Mesers. Cranston, and Mesers. Perkins of Coventry, at eace supported me and promised to send Roses for exhibition. nurserymen with but two exceptions sent glorious collections of foliage plants and flowers. Local amateurs poured into our two tents grand specimen plants of all sorts, with such fruits as Pines, Peaches, Nectarines, and Grapes. We had a fine day and took nearly £8 at the gate, so we find ourselves with a good round sum in hand in case of a rainy day next year.

But I must say a word about the Show. Everybody was more than satisfied. The Roses were very good considering all things. Messrs. Perkins staged some wonderfully fresh and large blooms; perhaps the best were Alfred Colomb, Leopold I., Lælia, Sophie Ocquerelle, Annie Wood (marvellously fine) and Marguerite Bra coquerene, Annie wood (marvenously nine) and marguerite present (or Charles Lefebvre?); even Mr. Perkins was not sure which it really was. Mr. Charles Turner's and Measrs. Cranston's were not so fresh as Messrs. Perkins', for they had been cut the previous day, quite twenty-four hours before the Show was open. However, all were much admired, and many of the cottagers declared that they had never seen "real" Roses before. Let my brothers in the cloth take heart when they read that the first nurserymen in England will take the trouble to send boxes of Roses a hundred miles in order to encourage cottage horticulture. I may add, too. that Mesers. R. Smith & Co. of Worcester gave a prize of six Rose trees (to be delivered in November) to that cottager who staged the best six distinct Roses, and Mr. Perkins one of the Judges told me that the prize was well earned. Mr. R. H. Vertegans. F.R.H.S., of The Chad Valley Nurseries, Edgbaston, exhibited splendid specimens of Seaforthia elegans, Areca lutescens, Cocos Weddelliana, Curcultgo recurvata variegata, also some very fine plants of Lilium auratum, lancifolium album, and lancifolium speciosum. Perhaps their best exhibit was a very healthy specimen plant of the favourite Allamanda Hendersoni. Mr. Hewitt of the Solihull Nurseries also sent a splendid collection of plants, including among many others Hydrangea paniculata grandifors, Pancratium fragrans, a good collection of Pelargoniums, Caladiams, and Palms. All were arranged with consummate taste. I will only say now that we had a financial as well as horticultural success, and I verily believe that pluck and perseverance has beaten the bad season, and that we have soundly established the Yardley Wood Cottagers' Horticultural Society.—J. A. W.

CARDIFF.

THE Directors of the Cardiff Workmen's Cottage Company (Limited), who have built upwards of three hundred artisans' dwellings at Cardiff, have been holding a flower show on a some-what novel principle. It so happens that the Company's property is in one block of a dozen short streets, and not intermixed with other premises, and as a large number of the tenants cultivate window plants it was suggested by the Secretary, and cordially approved by the Directors, that the distribution of a few prizes to the best examples would be a great encouragement to the promotion of so laudable a taste in the future. It was considered best to make the awards on the plants as they stood in their places in the windows, so saving all trouble in removal, and bringing into play the taste of the competitors in the artistic arrangement as well as in the quality of the plants. The duties of Judge were undertaken at the request of the Directors by Mr. Pettigrew, head gardener to the Marquis of Bute, who is Chairman of the

Company, and on whose land the houses are built. The competition being open to all the tenants, and entrance fees not being asked for, the number of exhibitors was large, amounting to 146; and although some could count only as indications of good intentions for the future, the great proportion of really good examples were quite worthy the exercise of the well-known skill and experience of the Judge in making the awards. The prize fund was contributed by the Directors and the builders and contractors concerned in the erection of the cottages.

Among so many excellent examples it would be difficult to note individual excellencies, but a few remarks from the Judge may be useful as a guide for the future. Mr. Pettigrew says, "He was surprised to find so many good examples of window gardening in a district so lately formed as the cottages, and he considers the action of the Directors in originating a show of this kind as a step in the right direction and deserving of cordial support. It will be the means of developing amongst those workmen a taste for window gardening and a love of flowers, the cultivation of which affords so much enjoyment, and tends in a great measure to counteract the evil effects of the public house." In conclusion, Mr. Pettigrew said he met with much difficulty in judging so many streets for the first prize, and suggested that in future a first, second, and third prize might be given to each street.

TELEGRAPH AND TELEPHONE PEAS.

HAD Mr. Keetley (page 190) confined his remarks to the Peas that he had grown he would have had some sort of a case against me, but he has done precisely what he reproaches me for doing. I referred to Peas grown by Mr. Iggulden, Mr. Keetley refers to Peas grown by Mr. Cooling and "several others" whom he does not even name. It is a little amusing to be told that had I grown the Peas in the Orsett Hall Gardens for myself I should have found the two varieties mixed. is a compliment to Mr. Iggulden for growing them so true, to which he is quite welcome so far as I am concerned. I assisted to gather the Peas, to shell them, and to eat them. The rows were examined most carefully, and I am able to say the varieties were not mixed, and if Mr. Keetley asserts the contrary I am obliged to tell him that, not having seen the rows I referred to, he is not competent to judge on the matter. If he will again refer to my article on page 123 he will find that I specially restricted myself to the Peas grown at Orsett, and I have not a word to retract. I am glad to say that my eyes are sufficiently good to detect green from white pods and Peas, and smooth from wrinkled, and I think my palate is sufficiently sufficiently good to detect green from white pods and Peas, and smooth from wrinkled, and I think my palate is sufficiently suffici ciently sensitive to perceive the difference between Peas that are mealy and Peas that are buttery. So distinct were the two Peas at Orsett that I am certain that no unprejudiced person could have pretended that they were identical. I have nothing to do with Mr. Iggulden's opinions, Messrs. Carters' action, nor Mr. Culverwell's oversight. I simply recorded what I saw and tasted, and never thought of causing either pleasure or pain to individuals, least of all to Mr. Keetley, who for some reason appears to be more discomposed even than Mr. Culverwell; in fact I simply told about the Peas at Orsett what Mr. Keetley cannot possibly controvert, the-TRUTH.

ALTHOUGH the remarks of Mr. Keetley at page 190 are directed to "TRUTH" it is very evident they apply to all those who have written about the distinctness of Telephone Pea in this Journal, and as one of them I must inform Mr. Keetley that his teachings may be accurate so far as his own crops and those he has seen are concerned, but he is wrong in trying to make out that the character he imputes to Telephone is its correct one in all cases. I readily admit that he may have found some of the pods "light green" and others "dark green," and I would like to know on which variety of Pea this cannot be observed; but no person would think of making this a leading point to judge the distinctness of the Pea by, as it is well known that the light green or dark green in the pods are often only indications of age. All Pea pods when they become slightly old assume a light colour, while the younger ones on the same stem remain dark green. I never saw a Pea or its differences more fully and accurately described than Telephone was by "TRUTH," and so far as my experience and observation of it in the garden here goes I entirely coincide with him.—J. MUIB, Margam.

GLOIRE DE NANCY BEGONIA.—Referring to the remarks about this variety in the Journal of Horticulture, August 21st, page 145, I quite agree with Mr. Wm. Potten that it is one of the most useful varieties we have. I would like to have your Dracocephalum Ruyschianum, with its long spike of blue

opinion of the enclosed flower, which has been taken off a small plant only 6 inches high and at present quite covered with bloom, each flower being perfectly double and fully 3 inches in diameter. The one I send having been too long on the plant is now, as you will see, rather old.—O. G. ROBEETS.

[It is the finest flower we have ever seen, and resembles a Turban Ranunculus.—EDS.]

BITTON VICARAGE.

BITTON is a very pleasantly situated village about midway between Bath and Bristol, and as it lies in a valley through which the river Avon flows evidences of luxuriant growth in both pastures and foliage are seen all around it. The trees are fine; and this year, while it has been bad for most things, has been ex-ceptionally good for foliage, the constant moisture suiting them, while the bitter east winds were over before the young leaves burst forth, and I do not remember ever seeing a greater wealth of foliage than there is at present. A situation like this is peculiarly susceptible to frosts; and although, generally speaking, the Bath district is mild and genial, yet in the last winter it (so trying everywhere) fell with peculiar severity on the west of England, and hence very lamentable gaps have have been made in the choice collection of herbaceous plants and shrubs for which the vicarage garden of Bitton is so famous. As we went round the garden it was with many a sigh of regret that Mr. Ellacombe pointed out here a wall completely denuded of its creepers, here a gap made by a choice shrub having been killed, in another place a plant that had been cut down struggling up again into life, in another place a label, which was all that remained where a plant ought to have been, and to such a lover of the hardy garden as Mr. Ellacombe this is no slight trial. Many of the plants have a history; have been collected on some pleasant tour, and bring to memory some lovely spot in Alpine scenery or the mountain districts of our own land; others have been the gifts of friends of whom some are in the "Land o' the leal," and so the losses are more than their mere intrinsic worth. The garden is one which would in no way strike the ordinary visitor. You see no grand blaze of colour, no polychromes or carpet bedding which are the special pride and glory of many a vicarage. There is no attempt at method—any spot that is most suitable for any particular plant is seized upon; and hence all primness, and, indeed, if one must say it, neatness, is taken away. To some eople indeed such a garden is an abomination. A near neighbour of mine took the duty of a brother parson who is famed for his herbaceous plants. Of course as my friend had a large garden of his own I imagined he would have been delighted, and with a touch of envy almost I asked him, "Well, what did you think of Blank's garden?" His reply was, "Referens horresco. Never saw such an untidy place in my life; and there seemed to me to be nothing but rubbish in it." With what different eyes one sees things!

Although probably the earlier months of the year are those in which the garden of a lover of herbaceous plants is best worth seeing, yet go when you will there is always sure to be something noticeable, something, too, which always adds variety to the nosegay-a most desirable point when we see the greater portion of these in friends' houses made up of Pelarconiums and Calceolarias. Among those plants suitable for this purpose, and at the same time graceful and elegant in the garden, I noticed Anthericum graminifolium, a lateflowering species having long spikes of small white flowers. Montbretia Pottsii was pretty enough (I saw it since at Mr. Ware's), an Iridaceous plant nearly allied to Tritonia, but I do not think so pretty. The flowers are small as compared with the size of the plant, and only two or three of them open at a time. It seems to be a somewhat over-rated plant. Conspicuous by a grand spike of bloom was Yucca Ellacombei; it was a grand pyramid of bloom, the outside of the petals being tinted with reddish crimson. It was (so Mr. Ellacombe stated to me) seen in the garden there many years ago, nothing being known of its history, and so named by a late dis-tinguished botanist. It would seem to be a variety of Yucca superba, a grand pyramid of which is now in bloom in the garden of the vicarage at Ashford in Kent. Lythrum alstum and roseum are handsome plants with long spikes of flower. Curiously enough the individual flowers open at the top first, and then gradually going down the stem; the

flowers, was also a conspicuous object. Eulalia japonica variegata is a very beautiful Grass, perfectly hardy and very striking; while Eulalia zebrina has the variegation disposed in bands across the leaf instead of longitudinally. Œnothera speciosa was in fine bloom, and is certainly one of the most beautiful of the species; the flowers are of a delicate paper white, suggesting at a distance a Meconopsis. It is, like its congener, sweet scented and free flowering; while, as it is only 2 feet high, it has not the rampant character of many of them. Fuchsia procumbens has proved perfectly hardy here, and with its curious little neat orange and blue flowers is well worth a place on any rockwork where it can be allowed to creep along the ground and not smothered by larger plants; while the sweet little Anometheca cruenta, a little bright flower, not so often seen as it ought to be, was perfectly at home in many parts of the garden. Many Lilies were doing grandly, although neither auratum nor candidum was quite happy; but L. dalmaticum Catani had upwards of forty of its blackish-purple flowers. L. Maximowiczii, rich citron spotted with black was fine. L. Batemannize was also very pretty, and is one of the best additions to our Lilies that we have lately had. The colour is a peculiar shade of apricot without any spots, apparently very vigorous. L. pardalinum and L. californicum were also in very good condition; and what more striking plants can there be in a flower garden than these stately and beautiful Lilies? There had been a fine bloom of some of the different varieties of Iris, and Iris Kæmpferi had done very well. I have not yet been able to grow these in my garden, but must try again, for they are very ornamental. Adenophora suaveolens was very pretty and sweet with its blue Campanula-like flowers. Delphinium Batesonæ is a very fine dazzling blue Larkspur, dwarfish in habit with branching spikes. I do not recollect seeing this before, and it is certainly worthy of a place in any garden where herbaceous plants are grown. Another fragrant flower was the sweet-scented Vine which was growing up the stem of an Acacia. Crinum capense had stood the winter well. Cypripedium spectabile had been very fine, but was of course now over. Amongst Phloxes, P. Van Houttei was very beautiful and is a very fine herbaceous plant. Amongst the Sedums I specially noticed were speciosum and pulchellum. Of course there were varieties of Phlox, Dianthus, and in spring the garden had been gay with numerous choice bulbs; and pro-bably there is no class of plants more ornamental than that of hardy bulbs. They begin early in the season with the Cyclamen, continue on throughout the summer and late into the autumn.

There was a charming little white Rose called "Little Pet," which Mr. Ellacombe said he had obtained from Mr. Pilgrim of Cheltenham, that was very pretty and fragrant. Very beautiful, too, is Rosa rugosa, and its white variety rugosa alba, with large single flowers and enormous heps of a peculiar shape, making it very ornamental in the autumn months, as I saw it again at Mr. Ware's the other day in great

Besides the herbaceous plants Mr. Ellacombe has a choice collection of flowering shrubs, but it was too late for these. He spoke highly of Fremontia californica and Raphiolepis ovata, but was not particularly enamoured of the new American Hydrangea Thomas Hogg. There is assuredly in this class of plants for those who have space a fine choice wherewith to ornament their shrubberies. We have been so much in the habit of running upon evergreens that flowering shrubs have been to a great extent neglected; but there is a turn in the tide, and the many beautiful things that there are amongst them are being rapidly sought after. Their deciduous character is in our climate of late spring frosts rather in their favour, for they escape the severe cutting-up to which evergreens are exposed; and while after such a winter as the last, when the Laurustinuses presented a miserable browned appearance instead of its snowy whiteness, the deciduous shrubs retarded by the long winter came out in great beauty.

I have thus endeavoured to show what a wealth of beauty there is in this delightful vicarage garden. Unfortunately my visit was a too rapid one, or I should have been enabled to take further notes of its contents, but I hope I have said enough to show that it is well worth a visit, and I think I can answer for its enthusiastic owner that he will be most glad to show its treasures to anyone who appreciates his pets and is not on the look-out for the last new thing in bedding-out. This they will not find there, but to all who love not only our old-fashioned border flowers but also all the more recent introductions amongst hardy plants, Bitton Vicarage garden

has been for a long series of years, and we hope may yet continue to be, classic ground.—DELTA.

ONIONS IN 1879.

Amongst gardeners and garden holders generally the Onion crop is always considered an important one, and although this is undoubtedly the case it appears that it is even of more consequence than many are aware of. The Right Hon. W. E. Gladstone, speaking the other day on gardening to the cottagers of the Hawarden Horticultural Society, stated, amongst other interesting facts of the kind, that £414,000 worth of Onions was imported into this country annually. Whether it would not be well for farmers and others complaining of bad crops to devote more land to the cultivation of this crop, and thereby produce a commodity for which there is so much demand, is a matter worthy of consideration. No crop is more easily grown than the Onion, and none is more certain to become useable or saleable. In seasons like the present, when many crops both in garden and field fail to become of the most ordinary value, Onions are the very opposite, as the weight of a light crop of small bulbs is equal in value to a corresponding weight of large bulbs.

In many instances the crop is lighter this season than it has been for some years. Last year we had several bulbs larger than they are this year, but yet the crop is good, the bulbs averaging from 10 to 12 inches in circumference. The seed was sown in well-manured ground on the 10th of March. Celery was the preceding crop. The soil is so retentive that for hours after a heavy shower or a wet day the water may be seen standing on the surface in pools. It is so bad in this respect that when the seed was sown I had grave doubts about ever seeing the young plants should the season turn out bad, and although it has certainly been the case they have succeeded much better than I expected.

Our main piece of Onions is on a quarter of ground measuring 30 yards by 12; 2 ibs. of salt was sprinkled on this just before the seed was sown and hoed in. No beds were formed, the rows following each other 15 inches apart. The seed was covered over with a mixture of old potting-shed soil, soot, and wood ashes. When the young plants were about 2 inches high other 2 ibs. of salt was thrown over them, and this was repeated some weeks after, the object being to keep off the grub, which it thoroughly succeeded in doing. Apart from this, running the hoe between the rows once or twice is all the attention they received. Many of them have just (Sept. 2nd) been drawn up and laid down to dry. All will be stored in a dry shed by the middle of this month. Those with the thickest necks will also be kept separate, as very often they keep as long or longer in sound condition than the larger bulbs. Some varieties keep better than others. James's Keeping is still one of the best in this respect; but to make these notes more convenient I had better put the names of those we have grown here this season with their characters in the following order:—

Webb's Banbury.—I mention this first because in my opinion it is the most handsome of all. It forms bulbs quickly, and has a wonderful tendency to remain small in the neck, and as the bulbs are very flat they become handsome in shape. It keeps very well, and is altogether a most useful variety.

Sutton's Reading.—This resembles the former in a great measure, but is slightly more conical. With us the bulbs come very even in size and form, and for a main crop we consider it second to none.

Carter's Naseby Manmoth.—This is more like the Banbury than the last-named, being low in the crown, a great percentage coming with small necks, and the whole forming a very even pretty crop. I consider it is the best form of the White Spanish in cultivation.

James's Keeping.—I mention this next owing to its keeping qualities being so superior. In this respect it is the best variety we possess; and wherever sound Onions are wanted, say until the following May or June, this variety should be grown. The four named above are superior to any of the following:—

Sharpe's White Spanish.—This is much after the style of Naseby Mammoth, but in size, shape, and general character it cannot be compared to that variety.

cannot be compared to that variety.

Williams' Magnum Bonum.—This is quite a different type from any of the preceding, as it is dark in colour and of a long conical or Pear shape. The necks are mostly inclined to be thick, and the bulbs of large size. In this respect it much resembles

Barr's Oporto, which is of the same shape only more erect in growth and not so dark in the skin. At the present time it looks more like a last-autumn-sown Tripoli than anything else, and although it has not been tried here for that purpose we fancy it would be as suitable for sowing in autumn as spring.

Trebons.—In shape and style of growth this resembles the last-named, but it is a more clear plate yellow in colour. The bulbs become very large in size, and in good summers they have been grown 1 lb. in weight in this neighbourhood.

Bedfordshire Champion.—Not many years ago this was grown for a main crop in many places, but I think it is now quite superseded by several of those first named.—A KITCHEN GARDENER.

ROSES FOR TOWNS.

A STORY is told of a man who assured a friend that he was very musical indeed. "What instrument do you play?" was the natural question put; to which he replied, "None at all, but my brother plays the German flute." On the above principle I may say I know something of smoky gardens and Rosegrowing near towns, for my brother lives in one of the most smoky districts of the West Riding. This is my old home, and still has most of the old attractions, so that I often visit it and when there spend much time in the garden. My brother has a large rosery as well as a span-roofed house to grow Teas in.
His experience with regard to one Rose, Général Jacqueminot,
is totally different from "BICEPS'S," who says that the old Jineral, as they call him in Yorkshire, is useless for growing near towns, and he invites opinions from others on this point. No Rose does better with my brother than this grand old Rose. He grows it in all sorts of ways—on its own roots, on the Manetti, and on the standard, and perhaps it does better on its own roots than on any stock. With regard to John Hopper, my experience is opposed to "Browres". The foliage is generally and the standard of the stand rally cleaner and the buds less attached than more thorny varieties generally are. As I do not know where "BICEPS lives, as he gives no intimation of his county in his letter. I cannot well advise about Gloire de Dijon; but in the West Riding and at my brother's all Teas, including Gloire de Dijon, refuse to grow.

With regard to duplicate Roses a few words from me are, I think, required in answer to "A. P.'s" concluding paragraph on page 167. "A. P." is kind enough to censure me as follows—"I should not have taken up my pen were it not for "WYLD SAVAGE'S" remarks relative to Sultan of Zanzibar. I think such a rosarian as Mr. Paul (who sends out both Roses) would be likely to know whether those he was sending into commerce were dissimilar or not; and seeing what beautiful Roses he has from time to time presented us with, I think we ought to be careful in our remarks respecting them." In answer I would ask "A. P." first to look at my article again and see if I was not more than careful in the way I apoke of the two Roses. I qualified my remarks by saying that my observations were taken from one nursery alone, that the proprietor of it was a little in doubt whether he had got the right Sultan, but that he could see no difference in his own plants, although visitors had brought blooms to the nursery quite different from those of the Sultan he had bloomed.

So much as to the caution and care I used in the wording of my letter. With regard to the good taste of writing anything concerning Roses sent out by Mr. George Paul, I may say that the Rose is the flower upon which I am more parti cularly engaged, and that I endeavour to give your readers any novel or interesting information that I am able. With this object I spent many days at the only large Rose nursery within forty miles of my home, therefore the article on duplicate Roses was the result of much labour and care. No more interesting subject which is not worn threadbare on the subject of Roses presented itself to my mind, and if I may judge by the number of answers I have had I am not alone in my opinion. If it is any comfort to "A. P." I may tell him that Mr. George Paul is not offended at my article, and that so far from resenting it as an impertinence he has written a long letter and sent me blooms of the two Roses, only anxious, as he says, to "assure so good a judge as myself of their distinctness."— WYLD SAVAGE.

PAINTED LADIES AND SILVER Y's.—It was remarked long since by the old entomologists that in a year when Lepidoptera generally are scarce a few species appear in special prominence, and the butterfly and the moth of 1879 seem to be the Painted

Lady (Vanessa Cardui) and the Silver Y (Plusia Gamma). The former of these does not concern the horticulturist except as an ornament of the parterre, for the caterpillar feeds on Thistles; the latter, however, is likely to prove a source of annoyance hereafter. Although the caterpillar of P. Gamma feeds on a variety of plants in the open country, the moth enters gardens freely, flying by day over the flowers, and in such seasons as the present many of the females will deposit their eggs both in the flower and the kitchen garden. I have just received a young brood that were feeding upon the Chrysanthemum. Leaves should be examined for their patches of eggs.—J. R. S. C.

NOTES AND GLEANINGS.

THE annual report of the PELARGONIUM SOCIETY just issued shows that the Society is in a prosperous state. Each year since the Society was formed in 1875 the amounts offered in prizes have steadily increased, the increase of 1878–1879 being particularly marked, and the balances in favour of the Society have also increased—namely, from £20 8s. 4d. in 1875 to £70 15s. 8d. in the present year. The Society's income this year was £121 15s. and the expenditure £114 17s. 5d., leaving the balance above named. The report shows with great clearness the position of the Society, and will be submitted for adoption at the annual meeting of the Society, which is announced to be held at Chiswick on the 23rd inst., when officers for 1880 will be appointed and the Pelargoniums grown in the gardens will be inspected. Although the report is generally so satisfactory, it contains a regret "that a larger proportion of the members who are growers do not compete with spirit at the exhibitions, and that a considerable number of Pelargonium growers residing at a distance do not as yet see the advantage of supporting the Society, and thus encouraging the advancement of the flower in its several forms."

— WE have received the schedule of prizes for the seventeenth Exhibition of CHRYSANTHEMUMSAND FRUIT, announced to be held in St. George's Hall, Liverpool, on November 18th and 19th. All the prizes for Chrysanthemums are open to all exhibitors, and there are prizes also for plants and fruit. Mr. R. Wilson Ker, 6, Basnett Street, Church Street, Liverpool, is the Honorary Secretary.

THE members of the SHEFFIELD GARDENERS' ASSOCIATION with their friends to the number of about 350 went on the 2nd inst. by excursion train to Creaswell station for Welbeck, the seat of the Duke of Portland, who had given permission for the party to be shown through his establishment. They were conducted by Mr. Carr, the head gardener, through the immense ranges of vineries, fruit houses, plant stoves, &c., and from thence to the Abbey and over the terraces, skrubberies, and pleasure grounds. The series of underground tunnels, with the lakes, skating rinks, grottees, &c., which have all been constructed by the present Duke, proved great sources of attraction to the visitors, who spent altogether a most enjoyable day, and were highly gratified with the kind and courteous reception they met with at the hands of the authorities at Welbeck.

—— It is not usual to find PRIMULAS flowering at this season of the year, but Messrs. James Carter & Co. have sent us blooms of their new Fern-leaved variety Prince of Wales. The flowers are fringed, semi-double, and of a rich rosy crimson colour—distinct and attractive.

WE understand that the fine BLACK HAMBUNGH GRAPES exhibited by Mr. J. Witherspoon at Bishop Auckland on the 13th ult., after being kept in water were again exhibited at Lumley on the 25th, Durham the 26th, and North Shields on the 27th, and each time took first prize in good competition. The Fruit Show at Durham was, we are informed, the best of its kind that has been held in the north this year.

THE mode of UTILISING GREEN GRAPES practised by Mr. Wildsmith, gardener to Lord Eversley, Heckfield Place, deserves to be widely known. The berries are placed with a little water in an oven where a suitable temperature is maintained, and afterwards strained. The juice is boiled down with sugar, and forms a fine red transparent jelly of excellent flavour, as we can testify, having tasted some at the last meeting of the Royal Horticultural Society.

— MR. R. ROBBINS, gardener to Sir E. A. H. Lechmere. Bart., M.P., Rhydd Court, Upton-on-Severn, informs us that he sent a TRENTHAM HYBRID MELON to table on September 3rd. On cutting it open the seeds were found to have germinated

and produced small plants with roots and seed leaves quite expanded. The Melon was of excellent flavour and of medium size. Two of these small plants were enclosed, and their cotyledons were quite green.

SEPTEMBER, writes Mr. William Taylor from Longleat, has made its appearance with both frost and sunshine. We have now had several days of most beautiful bright weather, but the nights are very cold; the minimum temperature at 4 feet from the ground for the 1st, 2nd, 3rd, and 4th were respectively 35½°, 37°, 37°, and 42°. Thermometer, when on the grass on the morning of the 1st, when the temperature was the lowest and the grass was quite stiff in places as late as 7.30 A.M.; on the 2nd, 3rd, and 4th the temperature registered on the grass was 32°, 31°, and 36½°. The maximum in the shade for the four days has been 70°, 72°, 71½°, and 70½°. The walls have been warmed by the sun, but it is a bad look-out for late fruit on standard trees.

BONUM POTATO is one of the very few varieties that has resisted the disease. Some varieties have been so seriously affected that the crops are nearly worthless, but of Magnum Bonum not a tuber is touched. A new round variety of the name habit of growth as Magnum Bonum obtained from Messrs. Sutton is also similarly free from the murrain, which has attacked with great virulency other varieties in the same plot of ground.

THE SUMMER, now rapidly approaching its close, has not been a favourable one for the weather prophets. summer was predicted because the season immediately preceding at the antipodes was exceptionally dry. That theory of the weather has proved unsound; indeed, to come nearer home the predictions issued from the London Meteorological Office, which are published daily, have been very often extremely faulty. Bearing those facts in mind there is not much encouragement for indulging in prognostications relative to the forthcoming winter; but no harm can be done in advising that preparations be made for frosts. It is not unlikely that these may be early, seeing that so little heat has been absorbed by the soil, the surface of which is exceptionally cold for the time of year, and frost is likely to occur the sooner; indeed, it has occurred. We saw lawns crisp with ice on the 1st inst., and have heard of instances where the thermometer has been from 2° to 4° below the freezing point. Slight touches of frost, even if nearly imperceptible, are often very injurious to certain plants. Cuttings of such plants as Heliotropes, Coleuses, Alternantheras, and others similarly tender never strike well if they have been ever so slightly injured, neither do tender plants winter well if they have been exposed to the frosts of autumn before being potted and placed in their winter quarters.

— Mr. John Morgan, late foreman at Blenheim Palace, Woodstock, has been appointed gardener to the Princess Mestchersky, Daughino, Russia; and Mr. John Marsh, succeeds Mr. Lee as gardener to Lady Aylesford, Offichurch,

Bury, Leamington.

— In our report of the Crystal Palace Fruit Show Mr. D. Wilson was credited with the first prize in the class for three dishes of Nectarines, which we are informed was awarded to Mr. Bannerman, gardener to Lord Bagot, Rugeley, for a

dish of very fine fruit.

ONE of the most beautiful flower gardens we have seen this year is that at HOLME LACY, near Hereford. As is well known by readers of the Journal, Sir Henry Scudamore Stanhope is an earnest horticulturist, and takes great interest in and has an intimate knowledge of both fruit and flowers. The flower garden, which is nearly 200 yards long by about 50 wide, is bounded on three sides by fine Yew hedges, and is further sheltered by a belt of trees on the north. This shelter has probably conduced to the bright condition of the Geraniums which, although not so floriferous as usual, are yet remarkably good for the season. A great number of varieties are grown in trial beds, and the best of these only, whether they are old or new, are admitted to the flower garden. Amongst the old varieties retained are Tom Thumb, Waltham Seedling, Beaten's Indian Yellow, Silver Nosegay, and Lord Palmerston. A little more modern are Vesuvius, Fire King, and Mrs. Haliburten. The last-named is found the best of all the pinks for hedding. Many of the Chilwell varieties, such as Arthur Pearson, Mrs. Jacoby, Rev. S. Hey, Sir Henry and Lady Stanhope, and some others, are represented by splendid beds. The colours are so well arranged, and show to such great ad-

vantage as surrounded by the fine Yew hedges, that there is no wonder that hundreds of visitors flock to enjoy the garden on the days kindly set apart by the owner to enable them to do so.

— MR. JESSE ALLGROVE, for over fifty years a faithful servant to Messrs. Osborn & Sons, died on the 17th ult. at the Sunbury Nursery in his 80th year. He was for many years manager of the nursery, and in this capacity gained the esteem and respect of his employers and all who knew him.

PORTRAITS OF NEW AND NOTABLE PLANTS.

ASTER TOWNSHENDII. Nat. ord., Compositæ.—"It is remarkable that so beautiful a plant should have escaped the notice of the many excellent botanists and zealous collectors that have explored the Rocky Mountains of Colorado, and that it should find no place in the synopsis of that Flora published in 1874 by Messrs. Porter and Coulter. It was raised from seeds presented in 1877 to the Royal Gardens by Richard B. Townshend, Esq., a gentleman who has resided in Colorado, and to whom the Gardens are indebted for other valuable contributions from that interesting country. The seeds vegetated freely, and the plant flowered profusely in September, 1878."—(Bot. Mag., t. 6430.)

CALCEOLARIA DEFLEXA. Nat. ord., Scrophulariaceæ. Native of Peru.—"C. deflexa was introduced into cultivation by Messrs. Rodger M'Clelland and Co. of Newry."—(Ibid., t. 6431.)

CYPRIPEDIUM LAWRENCEANUM. Nat. ord., Orchidaceæ.—

CTPRIPEDIUM LAWRENCEANUM. Net. ord., Orchidaces.—
"C. Lawrenceanum is one of Mr. Burbidge's discoveries during his recent expedition to Bornee, in the service of the Messrs. Veitch. Mr. Burbidge states that he found it on sandstone and limestone rocks in shady forests at an elevation of 2000 feet, sometimes attaining 3 feet in height. It flowered in Messrs. Veitch's establishment in December, 1878, and was named by Dr. Reichenbach after Sir Trevor Lawrence, Bart., M.P., the possessor of a renowned collection of Orchids, which the author of the species describes as being of exceptional richness and beauty." (18th) 4 6432)

of the species describes as being of exceptional richness and beauty."—(Ibid., t. 6432.)

CHIONODOXA LUCILIE. Nat. ord., Liliaces.—"It was discovered by Boissier in June, 1842, flowering amongst the melting snows of the western Tmolus, above Dozdagh, at an elevation above sea level of 7000 feet. It was introduced into cultivation by Mr. G. Maw, who has given the following account of the circumstances under which he found it:—'The specimens were obtained the first week in May, 1877, in ascending the Nymph Dugh, east of Smyrns, at elevations of from 3000 to 4300 feet. At the lower level it was out of flower, but near the summit of the mountain a great mass of it was met with in full splendour, forming one of the most sumptuous displays of floral beauty I ever beheld; a mass of blue and white resembling Nemophila insignis in colour, but more intense and brilliant. Close at hand were Tulips of several species, yellow Fritillarias, Galanthus Elwesii, yellow Gageas of several species. Croci, Colchicum bulbocodioides, Scillas, &c.—a perfect paradise for the bulb collector and the botanist.' Mr. Maw adds that the Chionodoxa has proved itself perfectly hardy in the open ground at Benthall during the late exceptionally severe winter, and that the bulbs which he brought home in 1877 have increased in size and strength."—(Pid., t. 6433.)

CINCHONA CALISAYA VERA. Nat. ord., Rubinces.—"The C. Calisaya yields the most important bark for medicinal purposes of all the species—that known as the yellow bark: and it is also that the obtaining of which for cultivation in India was the principal object of Mr. Markham's famous journey to the border land of Bolivia and Peru in 1860. From the eastern slope of the Andes in that region Mr. Markham, assisted by his gardener Mr. Weir, brought 450 living plants of Cinchons, chiefly belonging to this species, to the Pacific coast, and thence to England, and the survivors to India; where, however, owing to many delays attending the transport, but few arrived in a living state. The difficulties, and indeed perils, encountered by Mr. Markham in this journey are described in his 'Travels in Peru and India,' a work containing not only a fund of varied information regarding the Cinchona trees, and the conditions under which they grow in the Andes and were introduced into India, but a deeply interesting

account of the extinction of the Incas in Peru, and of the execrable treatment they and the Indians received under the rule of their conquerors the Spaniards. Like the two other Cinchonas figured in this work—namely, the variety of this mentioned above and C. officinalis, the C. Calisaya has been flowered for the first time in this country by J. E. Howard,

Beq., F.R.S., of Tottenham, in whose conservatory it forms a small tree 8 to 9 feet high, blossoming in March."—(1bid., t. 6434.)

LAMPEOCOCUS WEILBACHI. Nat. ord., Bromeliaces.—
"It has been in cultivation a long time, but is still rare in this country. It was first described from a specimen that flowered in 1854 in the Botanic Garden at Copenhagen; and again from a plant introduced about 1860 from Brazil by Monsieur de Jonghe of Brussels. A specimen flowered lately in the Kew collection."
—(Ibid., t. 6435.)

SOLLYA LINEARIS.

THE attractive little plant represented in the annexed engraving is the prettiest of the few species constituting the genus Sollya. Like its relatives S. heterophylla and S. Drummondii it is a native of Australia, whence it was introduced about forty years ago. In habit it is slender and scandent, with linear bright green leaves and very numerous deep blue

Fig. 24.-Sollya linearis.

pendulous flowers, which are succeeded by long seed pods that remain on the plant for a considerable time. The plant is easily cultivated, and when trained over a pyramidal trellis, as we recently saw a specimen in the temperate house at Kew, it is really charming. It thrives in a greenhouse temperature either in pots or planted out, and requires a soil composed of loam and peat with an admixture of sand, or the peat may be omitted.

WILD PLANTS.

I BEG to thank "H. B. B.," page 150, for the very interesting additional remarks he has made to my previous list of hardy native plants, the study of which I am sorry to see so much neglected at the present day. Wild plants have a charm entirely their own, and I well remember almost envying a fellow traveller on a coach top and the smiling approval he received from all when, on the coach stopping to change horses at an hostelry on the edge of a wild moor, the gentleman alighting, as it was customary for most people to do at such times, instead of lingering about the door of the inn went back a little distance and industriously employed himself in gathering aprigs of the Bog Myrtle (Myrica Gale), which he had spied in passing by, and presenting first the ladies and then some of the gentlemen with a few sprigs of the sweet-scented ahrub. It was pleasing to see the delight of the recipients.

Nothing in cultivation could be so plentifully obtained; and I am not sure but this Gale would suit a fashionable wedding bouquet as well as the orthodox Myrtle. But it is not my purpose here to dilate on wild plants in detail, for I have been so long estranged from them that I can recall but few to my memory that are of especial interest unless it be Primula farinosa, which being met with in few localities in a cultivated country was at one time regarded as rather a choice plant.

country was at one time regarded as rather a choice plant.
Was not the purple Euphrasia mentioned by "H. R. B."
Bartsia odontites? a very common plant, often met with at the same place as Euphrasia, and often found most plentifolly by the lane sides of a cultivated district. It is very abundant, and certainly not by any means a choice plant; while Erythrea Centaurium, often found in similar situations, is pretty, and I believe is often met with in gardens. But as I have said before, I do not mean to enter into the merits of particular plants, but again to call attention to them as a whole, and to claim for them a share of that attention which seems to be directed to one or two fashionable objects alone.—J. Robson,

A DAY IN HERTFORDSHIRE.

A JOURNEY of rather more than a hour's duration transported us one dull day in September from the busy metropolis to the quiet, ancient, and unfortunately not very clean town of Hertford, with its crooked narrow streets, multitudinous beershops and breweries. Old enough it certainly is, but by no means venerable or picturesque, and with all deference to the local authorities we venture to think that the sanitary arrangements in respect to unpleasant odours are open to much improvement. But our business was not with the charms or defects of the town, for we were bound on a short visit to two of the many gentlemen's seats in Hertfordshire—the Goldings and Woodhall, the latter of which has a claim to a place in history, and both afford examples of "good gardening." and that was sufficient to induce us to visit them.

ing," and that was sufficient to induce us to visit them.
WOODHALL is the country seat of Abel Smith, Esq., Member of Parliament for the county of Herts, and is situated about four miles north-east of Hertford. The mansion is spacious and most pleasantly located, being placed on rising ground in a very picturesque portion of the park, and commands an extensive view of that undulating well-wooded accency peculiar to the county. At the lower portion of the park near the farm a small winding stream like a silver streak adds considerably to the beauty of the prospect. The park comprises about four hundred acres of extremely diversified aspect, abounding in fine trees, with the common Bracken in large vigorous patches fine trees, with the common Bracken in large vigorous patches underneath them, through which wander the graceful deer that appear to be very numerous. One noticeable feature there is the handsome drive as straight as an arrow which extends from the stables to the upper lodge, a distance of three-quarters of a mile. It is bordered on each side by mag-nificent specimens of Oaks, Beeches, Elms, &c., and in its course dips and then rises again towards the upper end. The stables, too, have been converted into quite an architectural ornament to the estate. Viewed from a short distance on the drive the front appears to be a handsome stone arch or gate surmounted by a small dome in which is a clock; in fact, until very close to the building its real character could not be detected. This is a highly commendable mode of combining use with ornament, and one that might be worthily imitated in many estates.

Now we come to the garden, the chief object of our visit. It is about six acres in extent, situated near the house, and is enclosed by walls, the kitchen garden being again divided from the portion devoted to the ranges of glass. At the upper part is the bothy once occupied by Sir Joseph Paxton, who at Woodhall commenced his gardening career as kitchen boy, and opposite the bothy is the residence of the gardener Mr. John Beale, who has most creditably had charge of the garden for thirty-two years. The first house we entered was the early vinery, which is in two compartments that form respectively the first and second in the order of forcing. With the exception of two white varieties Black Hamburgh occupies the whole of this range. The Grapes had all been removed, but the canes are remarkably vigorous and thoroughly ripened, and promise well for another season. The next range is about 120 feet long in three compartments, and contains the later Grapes. Muscat of Alexandria was bearing a fine crop of rather small bruches fairly well coloured, but the Black Hamburghs were excellent in size, colour, and flavour, and the crop was large. These two ranges have a south-easterly aspect, and the Vines have

both inside and outside borders. Pines are also grown to some extent, and exceptionally healthy and vigorous they were at the time of our visit. There are several other bouses devoted to plants, and in all alike the same care and practical knowledge of their requirements is evident in the clean fresh growth. Outside, the walls are worth a visit; one in particular with a south-east aspect to which Pear trees are trained, is about 200 yards long, and the crop of Pears is astonishingly great, although their satisfactory ripening is doubtful. Some of the best varieties are grown, such as Glou Morceau, Beurré de Bance, Marie Louise, Joséphine de Malines, Beurré d'Aremberg, and Winter Nelis. On another wall 130 yards long with the same aspect Peaches are in fine condition, the crops being large and the trees remarkably healthy. Of other fruits the crop of Plums is fair, Apricots rather poor, also Cherries; Gooseberries are sparse, but Currants about an average crop.

The kitchen garden is well kept, and all the crops are in excellent condition, one quarter of Brussels Sprouts being especially noteworthy. In front of the Peach wall referred to above is a long border most tastefully and effectively planted with scarlet and pink Pelargoniums, relieved by lines of Pelargonium Flower of Spring, Iresine Lindeni, and Purple King Verbena, and even in such an unfavourable season as the present one the appearance of the border is very beautiful, and we have not seen one that could rival it.

The flower garden is not very extensive, but is well kept, the beds being of various forms and planted in the ordinary style. Carpet bedding has not yet been tried there, but we think that some of the beds in the front of the house would be well adapted for this mode of bedding. Several fine trees are noticeable near the house, especially some handsome Copper Beeches, one being upwards of 60 feet in height; there are also

Fig. 23. Goldings.

some good specimens of the common Beech. We have briefly enumerated the chief points of interest, but to note in detail all that is to be seen and admired in a garden like this would require considerably more space than we have at our disposal; suffice it that our visit was an extremely pleasant one, thanks to the cordiality of Mr. Beale and his intelligent foreman Mr. Wells.

THE GOLDINGS is the seat of Robert Smith, Esq., brother to the owner of Woodhall, and by a singular coincidence the gardener, Mr. James Beale, is related in the same degree to Mr. John Beale of that estate. It is aituated three miles nearer Hertford than Woodhall, but, like the latter, it is on slightly elevated ground, and commands a pretty view, but not very extensive. The annexed engraving (fig. 25) represents the south side of the house and the flower garden. The tree near the centre is a handsome Copper Beech, and there is another at the left of the engraving; on the right is a bank of fine old Yews. The beds are tastefully planted in the ordinary manner; and although the Pelargoniums, owing to the unpropitious season, are rather deficient in flower, the general effect is good, and the contrast with the extremely well-kept lawn is very pleasing. The glass is not extensive, but there is an air of neatness everywhere that is not always found in more pretentious establishments. Grapes are remarkably well

grown, and some of the Muscat of Alexandria and Black Hamburghs were equal to any we have seen this season. Figs, Peaches, and Nectarines are excellently cultivated, judging by their general health and vigour and the fise crops of fruit the trees are bearing. Plants are not grown in very large numbers, but the Ferns are good, and in a small greenhouse Fuchsias are trained up the roof, and flower most profusely. Mr. Beale finds them invaluable for cutting purposes. The principal varieties are Souvenir de Chiswick, Venus de Medici, Sir Colin Campbell, Marquis of Bristol, and Rose of Castille. The kitchen garden bears good witness to the skill of the gardener, for it is remarkably well stocked, and the crops are in fine condition generally. Outdoor fruits are in fair numbers, especially Pears. Mr. Beale is evidently a thoroughly practical gardener, and one who takes great pleasure in his work.—Visitore.

FRUITS AND SEEDS.—At the meeting of the British Association, in the Department of Botany, Sir J. Lubbock, M.P., read a paper on this subject. He called attention to the differences presented by seeds, some being large, some small, some covered with hooks, some provided with hairs, some smooth, some sticky, &c. After observing that there were reasons for all

these peculiarities, he explained some of the more striking. In the first place, many seeds required protection from birds and insects, hence the shells or husks of the Beech, Spanish Chestnut, Horse Chestnut, Walnut, &c. The modes of dispersion by means of which seeds secured a sort of natural rotation of crops were next described. Some plants threw their seeds. Thus in the common Cardamine the outer membrane of the pod became very tense, and when ripe, at the least touch gave way at the base, and, curling up with a spring, threw the seed 3 or 4 feet. Common Geraniums threw their seeds, and some of the Cucumbers, but in these cases the mechanism was different. He then described the means of dispersion possessed by seaweeds and other low organised plants. Among the higher plants the seeds were transported by the wind. Sometimes the whole plant was thus blown about, as in the case of the celebrated Rose of Jericho. Many seeds were provided with a wing, which caught the wind, and these and kindred aids in dispersion were as various as the plants themselves. He then proceeded to the case in which the dispersion of seeds is effected by the agency of animals. In many cases the seeds were surrounded by a sweet fleshy pulp which was eaten, while the true seeds, being surrounded by a tough shell, remained undigested. Such fruits were generally bright in colour, such as the Strawberry, Peach, Apple. Current, &c., the colours, like those of flowers, serving to attract animals. In other cases the seeds adhered to animals by hooks and by sticky glands. The next point was that of seeds reaching spots suitable for growth. Most seeds, they knew, germinated on the ground; the Mistletoe however, was parasitic, and its seeds were embedded in a viscid substance, so that if dropped by a bird on a bough it adhered to it, and was in no danger of being blown or washed off. An allied species, described by Sir J. Hooker, which lived on the Beeches of Terra del Fuego, had four long feathery flexible appendages. By means of them it was blown from tree to tree, and as soon as the seed touched a twig the appendages twined round it, and thus anchored the seed. In some cases plants buried their own seed. This was the case with our Clover and the Ground Nut of the West Indies. In both cases the seed was forced into the ground among the grains. The Cranesbill's seed was pointed and clothed with short hairs, terminating with a spiral appendage covered with similar hairs. Now if one of these seeds was laid on the ground it remained quiet as long as it was dry, but as soon as it was damp the hairs on the seed commenced to move outwards, gradually raising the seed into an upright position with its point downwards. The spiral appendage then began to unwind, and if its hairs came in contact with any obstacle, such as a leaf or twig, as was most probable, the seed was then forced into the ground. The lecturer in conclusion called attention to mimicing seeds, the pods of which looked so exactly like worms that birds were induced to peck at them.

NOTES ON STRAWBERRIES.

IF those who write their experience on Strawberry culture would at the same time state in what part of the country the crops are grown, also the nature of the soil they have to deal with-whether clay, light loam, or medium-a much better conclusion would in most instances be arrived at. I would suggest also that nurserymen, than whom none else have the information so ready at hand, would do well to bracket together in their catalogues those varieties that fruit simultaneously, classifying them under the headings of earliest, second early, midseason, rather late, and very late. This would prove valuable to purchasers by enabling them to select their varieties for succession throughout the entire season, more especially to smateurs having but little acquaintance with the different varieties, and would doubtless lead to a more extended cultivation of this useful, wholesome, and delicions fruit.

Reliable information being of great importance to the readers of the Journal, I wish to correct what I conceive to be some errors on page 125. "C. P. P." contributes valuable information from time to time, but I think he was less accurate than usual when he described Rivers' Eliza and Coxcomb as late varieties. In my experience neither of them are late, and in this opinion I am supported by good authority—Mr. Rivers, who raised Eliza, and it is described in his catalogue as early. Coxcomb is also an early Strawberry. I have grown it for the last six years, having obtained it from Messrs. F. & A. Dickson & Sons, Chester, a firm noted for the correct nomenclature of its supplies. It is not quite so early as Black Prince, Alice

Maude, La Grosse Sucrée, and Early Prolific, all of which it succeeds; but I have President growing in the same bed as Coxcomb, and can always gather a dish of fruit from the latter three or four days earlier than the former, which is catalogued as an early variety. Possibly this is the first year "C. P. P." has fruited Eliza and Coxcomb; if so I can readily allow for his having classed them as late varieties, since all outdoor fruits are quite out of character this season as regards their usual time of fruiting, and although he may have fruit in September this year of those two varieties he must not expect it another season unless it should be similarly cold and ungenial.

The annual horticultural Exhibition is held here (Stone, North Staffordshire) during the first week in August, and only by shading the few remaining fruits on the plants a week or two previously to delay their ripening has it been possible to obtain a plate of Coxcombs for the Show when all the large fruits had been previously gathered. This year, however, the season being backward, its fruits were in abundance, and were exhibited in the finest form, which carried off the highest honours. Frogmore Late Pine succeeds it, and also excels it in flavour, but not being so hardy it requires a warmer and more sheltered position, with generous and attentive culture; it is then a grand variety, of large size and a good bearer. It has not done well here this season, as being in an exposed position it was injured by the severe winter and spring. The plant is not very robust, and the crop is not so large as that of Coxcomb, the yield of which is enormous here on a stiff clay soil. I have tried it on a lighter soil, and found it less pro-ductive and smaller in size. It is of very robust growth and very hardy; colour of fruit a bright salmon, surface even; seeds of a greenish yellow; flesh a pinkish white and rather firm, very juicy and of good average flavour; calyx not reflexed; shape—the largest berries mostly cock's comb, the oth bluntly conical. President has not set its fruit so well with me this season as heretofore; its flavour, too, has not been so good. In warmer seasons when thoroughly ripe its favour has always been superior to Coxcomb, but it does not produce so great a quantity of fruit on a clay soil as the latter does. I have not yet tried it on a lighter soil, but have heard of greater success having been obtained thereby.

In former seasons I have generally gathered my first Carcombs about the 22nd of June, finishing by the end of July or
the first days of August; President the 25th of June, finishing
about the 27th of July; British Queen June 26th, finishing
about the same date in July. This year my first gathering of
Coxcombs was made on the 24th of July, and the heavy incessant rains of the week ending August 24th have washed
clean away the fruits that might possibly have lasted the
mouth out had the weather been dry and fine.

Before closing my remarks I wish to advert to the size of Strawberries. When the largest Strawberry was being inquired after in your columns a few years ago the Rev. Mr. Radelyffe brought Concomb to the front, stating that "his man Stephie, who had then gone to Canada, had when in his employ measured its fruit with the tape, and found some 11 inches round." The dimensions seemed to stagger me, and doubts arose in my mind as to the accuracy of "Stephie's" measurement. But they are now entirely dispelled. A few weeks ago, when standing with a few friends in the midst of a plot of Coxcomabs, the reverend gentleman's assertion was adverted to. We resolved to bring to the ordeal of the measuring tape such fruits as we could then select (the largest having been gathered a few days previously) the result being that three thus measured each ranged close upon 10 inches round.—TROMAS FORMAN.

I AM sorry that Dr. Roden should feel aggrieved at my remarks about his Strawberries, and am quite willing to withdraw my observations, but he quite misunderstood me. I had no intention of being satirical or to disparage his efforts. Qui palmam meruit ferat. Mr. C. P. Peach said in one of his letters that he had tried several of Dr. Roden's seedlings and was willing to send a short report of them to the Journal, and my remark was merely to encourage him to favour your readers with the benefit of his notes, for which I thank him. Satire is a two-edged sword, which I think is out of place in the gardening world, where if anywhere there ought to be the peace and freedom from strife, which is too common elsewhere; and I would far rather extend the right hand of fellowship to a man any day, however humble or however poor his efforts,

than throw cold water on them or make them the object of | President, and Sir J. Paxton; the latter being in every respect ill-natured criticism .- AMATEUR, Circnester.

HORTICULTURAL NOTES .-- No. 1. NEWBURY AND DISTRICT.

ALTHOUGH comparatively of little importance and but little known, Newbury is a very busy and thriving little town. The streets are unusually commodious, and the houses and shops, &c., clean and well kept. It is situated on the river Kennet and the London and Bath road; but the railways of the present day have, as a matter of course, detracted considerably from the importance of the latter, in fact have spoilt the trade of the large old-fashioned inns which were so well patronised in the stage coaching days. To anyone on a horticultural tour Newbury presents a capital central spot from which several fine well-kept gardens can easily be reached. There is also some splendid scenery, and many historical spots and ruins, with the accompanying legends, which many tourists delight in. During the first week in August I inspected several fine gardens, and there were still more to visit had I time to have done so. Some of the gardeners at the places visited were very successful at the Newbury Flower Show held on August 4th; notably Mr. Atkins of Lockinge Park and Mr. Howe of Benham Park, both staging many well-grown plants and some capital fruit and vegetables in the various well-filled The Committee of the Society are all non-professional horticulturists, which is undoubtedly a mistake, as from its central position, and judging from the extraordinary attendance of visitors, this, with a little spirited and more practical management, might become one of the best shows in the county of Berkshire. After this digression I propose giving a necessarily rather brief notice of a few of the leading places in the district, commencing with the first, and in some respects the finest, place visited.

HIGHCLERE CASTLE.

This, the seat of the Earl of Carnarvon, is situated on the borders of Hampshire, and is about six miles from Newbury. The drive to it from that town is a very delightful one, the scenery in some instances being grand, and the views in the extensive park and grounds are very fine. Cedars of Lebanon are as plentiful as Oaks are in many parks. All are very fine specimens, and growing luxuriantly. In the grounds there are some become drooping in babit, the style of growth resembling that of the Hornbeam, which makes them very effective. Near these is a very fine specimen of Picea cephalenics, which, as far as I can judge, is from 70 to 80 feet high, and very symmetrical. It is considered by some to be the finest specimen in the country. There are also good specimens of Picea Pinsapo, Taxus adpressa; and of deciduous trees Juglene nigra, Sophora japonica, and Pavia californica are worthy of notice. The latter was flowering freely, and the Horse-Chestnut-like blooms are very effective. There the Horse-Chestnut-like blooms are very effective. There are large numbers of Kalmias, Azaleas, Rhododendrons, &c., grouped about the grounds, which are very extensive, but rather cheerless during the summer months in consequence of the flower garden being to a certain extent separated from them. The flower garden, forcing houses, and conservatory are situated in what probably was once a kitchen garden, the walls of which still remain. The conservatory, prettily situated, is very old-fashioned, and neither the contents of this mer of the other houses call for any special mention, all the structures in fact being unworthy of the surroundings. In the flower garden a number of Crinum capense were flowering freely, and in the hardy fernery the pretty little Cysto-pteris bulbifers is worthy of notice on account of the rapidity with which it spreads. The fronds are very light and useful for cutting. The kitchen garden is situated some distance from the Castle, and is well walled in and stocked with all kinds of fruit trees. The crop of Apples is poor, and the trees appear in an unhealthy state. Those carrying the best crop are the Wellington (Dumelow's Seedling), and Hawthornden. Pears are healthier, and are a very good crop, but rather small, the most prolific being Winter Nelis, Autumn Berga-motte, Beurré de Rance, and Hacon's Incomparable. Peaches, Nectarines, and Apricots are very thin; but Plums are a little better, the best being Kirke's, Denyer's Victoria, and Jeffer-The trees of Gooseberries and Currants, both here and nearly in every garden in the district, are in a very bad state, caterpillars being unusually destructive. The Strawberry crop was good, and the varieties preferred by Mr. S. Ross, who for many years has been head gardener here, are Garibaldi,

excellent. The vegetable crops were looking well, and are grown in large quantities to meet the requirements of the establishment.

SANDLEFORD PRIORY.

On the road back to Newbury I called at the residence of W. P. B. Chatteris, Esq., which is situated at about two miles from that town. The gardens here are principally famous for the splendid collection of choice named Rhododendrons, which is probably the finest private collection in the country. Mr. Brown, who for many years has been in charge of this place, has good reason to be proud of the Rhododendrons, more especially as he is the raiser of many fine varieties that are in the trade, for which, however, he has derived but little profit or renown beyond the immediate neighbourhood. That beautiful variety Lady Cathcart was raised here, and at the time of our visit there were numbers of plants in bloom, seedlings raised from that variety. The flowers are not large, but the tracces are fine and very compact, and in every instance nearly white. It is, on account of its late blooming, colour, and compact trues, a most useful variety, especially for cutting purposes. As before stated, the collection is remarkably large, and it is being annually extended, and as far as growth is concerned, is well arranged. In most instances a compost consisting principally of peat is made for them, but those in the natural soil are also growing in a vigorous manner. Kalmias and Azaleas are growing equally as well, and the whole must present a grand sight worth going many miles to see. The flower gardens are well kept. On the walls in the kitchen garden the Peach trees now appear very bad, in many instances three parts of the trees having had to be cut out. They no doubt were damaged by the severe frosts, and the uncongenial spring finished the ruin. This subject, however, will again be alluded to, to show the importance of giving protection to the trees in the spring. Here also Pears are small and very abundant on the walls, notably Marie Louise, Williams' Bon Chrêtien, Ne Plus Meuris, and Beurre de Capiaumont. The crop of Plums is thin, but Figs gave promise of a good crop, the variety being Brown Turkey. Small fruit was very abundant, but the trees are much damaged by caterpillars. The favourite Strawberries were President and Sir J. Paxton. Birds in this and other places have this season being unusually destructive. Not many plants are grown in the houses, but Melons, Pine Apples, and Grapes are in good numbers.

BENHAM PARK.

The pleasure grounds and mansion are in a state of transition, the proprietor, Sir B. Sutton, Bart., meanwhile residing at Barton Court, a few miles from here. We, however, found much to interest us in the many well-arranged fruit and plant houses, which really merit a more detailed account than our notes or memory will supply. Peaches and Nectarines are grown remarkably well, all being healthy and vigorous in spite of the very heavy crops borne by them. In most instances they are trained up the roof of either the back or front of the houses. The colour and flavour of the Nectarines especially were particularly good. Most of them are growing in a good loamy soil, the roots having access to both in and outside borders. The favourite Nectarine for all purposes is Elruge, and Royal George and Violette Hative are considered the best and most useful Peaches by Mr. Howe, the very practical gardener in charge. Figs also are grown trained up the roof, and nothing could be finer than the plants of White Marseilles and Lee's Perpetual (Brown Turkey) which conjointly occupy the roof of a house fully 32 feet long and 12 feet wide. From the former variety one hundred dozen good fruit had already been taken this season, and there is good find an advantage state of the still abundance showing. The earliest and perhaps the best fruit are gathered from the apex of the trees, but the growth is very equally distributed through the house. This is maintained by annually cutting clean out large and comparatively exbausted branches, laying in the young and more vigorous growth previously selected and trained for that purpose. Grapes in the different houses are all healthy and carrying heavy crops. Madresfield Court grafted on Black Hamburgh is very fine, without any sign of cracking. Black Alicante, too, is remarkably good; and there is one house planted entirely with West's St. Peter's. The crop is heavy and the bunches large, but the berries are set very irregularly, too many being seedless. It keeps well, and is much liked here. The crop of Melons is remarkably good, and they had previously had some excellent fruit. The varieties grown were Victory of Bath,

still the best for early work: Dell's Hybrid, which here is difficult to distinguish from the Victory of Bath; and Benham Hybrid, the result of a cross between Scarlet Queen and Victory of Bath. In its style of growth and productiveness it resembles the latter variety, but the colour of flesh is not fixed; in fact, alternates between the two parents—the fault of too many new varieties. Slacked lime and crushed charcoal mixed in equal quantities are heaped round the stems of the Melons, not as a cure but as a preventive of the canker. The house of Cucumbers was very fine, the growth being healthy and plenty of handsome fruit being abundant. The favourite variety both with Mr. Howe and the cook is Freeman's Yard Long. certainly a very handsome variety, particularly good for exhibition, is free-growing and prolific, and the flavour is much liked. Mr. Howe has most of the best varieties in cultivation.

The houses are distributed about the kitchen garden, and going from one to the other we noticed a large number of well-trained fruit trees on the walls, some of which, more especially Pears, were carrying heavy crops of fair-sized fruit. The best were Glou Morçeau, Marie Louise, Jargonelle, Jean de Witte, Hacon's Incomparable, Beurré Clairgeau, Beurré de Rance, Beurré Bosc, Beurré Diel, and Napoleon. Apricots do not succeed here, but Peaches are, for the year, remarkably good, the trees being both healthy and well fruited. This good result Mr. Howe attributes to the use of Parham's (of Bath) patent fruit-tree protectors, as previous to their introduction the Beach tree protectors, as previous to their introduction the Beach tree protectors, as previous to their introduction to Beach patents. duction the Peach crop was invariably a failure. This will be better understood when it is stated that the gardens are in a valley, and consequently suffer much from late frosts. These wall protectors are also in use at Englefield Park near Reading, and will be alluded to more fully when that place is remarked on. The crop of Apples is a poor one, the only exceptions being espalier-trained Cellini and Lord Suffield. Small fruit and Filberts were plentiful. The kitchen garden is well stocked with vegetables, everything in fact being well done. The Globe Artichokes were banked up with ashes during the winter, and to this circumstance Mr. Howe attributes their escape from destruction by frost which proved so fatal to many plantations in this and other localities.—W. IGGULDEN.

THE LONDON PARKS. HYDE PARK.

In consequence of the unfavourable weather of the present year the bedding in all the London parks falls far short of its usual brightness. The chief display of Hyde Park, as all who have once visited it well know, is confined to the series of beds that extend from the Grosvenor Gate to Stanhope Gate, between and parallel with the carriage drive and Park Lane. The beds are cut out in fine and well-kept turf, which for nearly half the distance is raised in the centre, the beds being in similar opposite pairs, while the portion near Stanhope Gate is flat, and the beds extend in a single row down the centre. The latter are usually devoted to carpet designs, but this season they are planted alternately with flowering plants. There is also a series of beds still nearer the road close to the Park railings. The forms of the beds are not very diversified, being oblong with rounded ends, circles, or what may be described as four-lobed, and there is a monotonousness in the edging which is not by any means pleasing. The beds in pairs on the raised turf near the Grosvenor Gate are all edged as follows:—First, Lobelia pumila; second, Alternanthera magnifica, and third, Pelargonium Albion's Cliffs, the centres being occupied with varieties of Pelargoniums. Some of the best Pelargoniums in these beds are Miss M. Holden, compact habit, well formed rich scarlet flowers in a medium-size truss; John Gibbons, rather strong in habit but bearing fine trusses of enormous flowers, intense glowing scarlet in colour, very effective; Jealousy, coarse habit, flowers small, of a bright salmon shade, and rather scarce; Letty Carr, very compact, with a neat truss of crimson scarlet flowers. One bed is planted with Pelargonium Ariosto and Viola Blue Bell intermixed, which would have been very pretty had the plants filled up the space a little more. A circle in which Albion's Cliffs is replaced by Crystal Palace Gem and a mixed centre composed of Iresine Lindeni and Viola Golden Gem is very pleasing; the latter is flowering very freely. The beds parallel with the above and nearer the Park boundary are edged with Lobelia Blue King and the golden-folioged Pelargonium Robert Fish—an extremely agreeable contrast; and here we may remark the Lobelia named has succeeded well, the fine light blue flowers being produced most freely; Lobelia Omen is also very distinct and fine. The centres are planted with Pelargoniums as in the other beds. The

single central beds are partly edged with Lobelia pumila. Alternanthera magnifica, and Crystal Palace Gem, some with Lobelia Blue King and Pelargonium Robert Fish, and the others with Pyrethrum parthenifolium aureum and Lobelia pumila; the beds near the road having an edge of Lobelia Blue King and Pelargonium Miss Kingsbury. Among the Pelargoniums forming the centres the following are noticeable:—Sir H. Stanhope, rather strong in habit, flowers well formed in good trusses, colour an intense dark scarlet; Col. Wright, large trusses of dark salmon scarlet flowers, very showy; Wordsworth, small truss of bright scarlet flowers, habit fairly good; Lucy, an excellent variety, even growth, large truss of bright pink abundant flowers; for quantity of blooms this variety surpassed all the others. A mixed circular bed of Viola Blue Bell and Pelargonium Princess Alexandra edged with Lobelia pumila grandis and Echeveria secunda glauca is very bright and pretty.

The carpet designs are generally good, two of which deserve particular attention. One that we have described as a four-lobed bed is edged with Echeverias, Pyrethrum, and Alternanthera mag-nifica, the groundwork being Pyrethrum, in which are formed heart-shaped designs of Sempervivum arachnoideum surrounded with fine lines of Alternanthera amoena and Golden Feverfew, lines of Mentha Pulegium gibraltarica radiating from the centre. The other is a circle, the groundwork formed of Alternanthera amoena and Sedum glaucum edged with A. magnifica and Eche-

verias, the central plant being an Aloe variegata.

Leaving that portion of the Park we turned in the direction of "the Row," between which and the carriage drive is a sheltered hollow where we find a few beds and some subtropical plants. Considering that these are all overhung by trees-no slight disadvantage this season, the plants appear much better than could be expected. A mixed circular bed has a groundwork of Alternantheras and Pyrethrums, lines of Chamæpeuce discantha, a central Dasylirion, plants of Sempervivum arboreum at intervals, and an edging of S. Haworthii. Another circle has a centre of Erythrinas surrounded by Pelargoniums, Calceolarias, and Lobelias; another much larger one has a central plant of Seaforthia elegans surrounded by small Cordylines, the design being somewhat complicated in Mesembryanthemum cordifolium variegatum, Pyrethrums, Alternanthera amoena, and Echeverias. Musas, Palms, and Tree Ferns are dotted about, two fine specimen Seaforthias being especially noticeable. The surface of the turf is pleasantly undulating and excellently kept. On the opposite side of the Row is a large circular clump of Hemp and Cannas margined with Funkia Sieboldii, all vigorous; also a creseent of Solanum robustum, Abutilons and specimens of Humea elegans with an edge of Funkias and Iresine Herbetii. A short distance west of that point is a charming nook known as "the dell," there the overflow of the Serpentine forms a little stream which is margined with Osmunda regalis, and the aloping banks on each side are planted with clumps of Phormium tenax variegatum and Bambusas, and single specimens of Monstera deliciosa, atania borbonica, Seaforthia elegans, and Musa Cavendishii.

Having thus briefly glanced at the chief points of interest in that aristocratic region we proceed towards Kensington Gardens, where we take the pleasant shrubbery walk that passes near the Albert Memorial. Among the shrubs are many very elegant species, which are not by any means so common as they desc One of these is Amorpha Lewisii, a papilionaceous shrub with light green pinnate foliage. It is very attractive and graceful, and contrasts well with the darker Hollies, Evergreen Oaks, &c. Paulownia imperialis is also noticeable for its hand-some foliage, which is very distinct. This tree flowered last year, but there is no appearance of bloom now. In front of the shrubs is a mixed border of Phloxes, Violas, Stocks, Marigolds, Veronicas, dwarf Sunflowers, Echinops, and numerous other plants in irregular clumps and patches. This walk is one of experience of the plants of the plants in irregular clumps and patches. treme beauty in the spring months when the numerous varieties of Cratægus are in flower, but even now it is not without attractions. The bedding at the south-east side of the Palace is usually very good, but it is rather disappointing this year, for, as in most other places, the Pelargoniums are nearly nowerless, but a ribbon border extending along the side of the lawn is prettily planted. The turf is in excellent condition, and a few Palms, variegated Agaves, Musas, &c., are suitably introduced.—L. C.

WORK FOR THE WEEK.

FRUIT HOUSES.

Vines.-The Vines in the earliest house should now be pruned if the wood is hard and well matured. Prune to a plump eye, having in view the keeping of the spurs as near the main rod as practicable. The house should be thoroughly cleaned, and if necessary painted. Remove the loose bark from the rods, and then wash them with a solution of soft soap, 8 ozs. to the gallon of water. If there be any mealy bug or scale wash the Vines a second time with the soapy solution, adding a wineglassful of spirits of turpentine and methylated spirits, and in case of mildew add flowers of sulphur. The walls should be limewashed, and all made as clean as possible, removing the loose soil from the top of the border, and replace it with turfy loam to which has been added a sprinkling of half-inch bones. Any Vines in an unsatisfactory state may be improved by partially lifting their roots, removing the old soil and relaying the roots in fresh compost; but this should be done before the leaves fall. The house after the Vines are pruned should be kept as cool as possible so as to induce complete rest. Vines in pots for early forcing should now be fully ripe and at rest. Supply only sufficient water to prevent the destruction of the root fibres. Later Vines in pots should be placed out of doors to ripen the growth, the south side of a wall or fence being preferable. Young Vines that have made strong growth will be late in ripening their wood, and may be assisted with fire heat and free ventilation until the wood is brown and hard. Continue a night temperature of 70° to 75°, and 80° to 85° or 90° by day for late Vines until the Grapes are thoroughly ripe, ventilating freely and keeping lateral growths closely stopped. If the roots of late Vines are in outside borders it is desirable to protect them from heavy autumn rains, as when the borders are chilled and soddened the Grapes do not keep satisfactorily. The necessity for protection is not so great where the Vines are planted inside. Ripe Grapes should be frequently examined, removing decayed berries, and maintaining gentle fire heat to insure a dry airy atmosphere.

airy atmosphere.

Peaches and Nectarines.—The trees in the earliest house will appear to the second have shed their leaves, or nearly so, and the house should undergo a thorough cleaning, it being a good plan to syringe every part of the structure with hot water (140° to 160°), which destroys insects and softens the dirt so as to admit of its speedy removal with a brush and soap. The trees should be loosened from the trellis so brush and soap. The trees should be loosened from the treins so as to admit of its being cleaned or painted, or the walls limewashed. The trees should then be pruned, thinning out any weakly growths not likely to carry good fruit. Beyond thinning out the shoots where too crowded no pruning will be necessary, as forced trees will not require to have the growths shortened back except for the production of shoots for averaging. The trees should be the production of shoots for extension. The trees should be dressed with tobacco juice or a solution of nicotine soap, 8 ozs. to a gallon of rain water, at a temperature of 90°, applying the solution with a brush. The loose surface soil should be removed and replaced with rather strong loam containing a sprinkling of half-inch bones. If the lights have been removed from the house it may be necessary to replace them to prevent the soil from becom-ing saturated by the autumn rains. Inside borders must not be allowed to become too dry, as the buds are liable to fall when in that condition. Trees in succession houses should, when the growth is free, be root-pruned or lifted as soon as the foliage shows indications of falling; if judiciously performed this will check their vigour and induce short-jointed fruitful wood. Any lifting or root-pruning should be performed before the leaves fall, affording a good watering to the roots afterwards, and syringing each evening for a few days. The trees will soon produce young active roots. In the latest houses a free circulation of air will be necessary, utilising sun heat by keeping the ventilators closer than usual, as with ventilation in the early part of the day the temperature may be allowed to run up to 80° or 85°, which will do more to ripen the fruit and wood than sharp firing in dull weather. A somewhat drier condition at the roots is desirable when the fruit is ripening, employing fire heat to maintain a night temperature of 60° to 65°, with an advance of 5° to 10° by day, which will admit of free ventilation. In unheated houses in duce ripening by a somewhat dry atmosphere. Keep the wood thin, and stop any growing shoots to about 12 to 14 inches, and all laterals closely to one joint,

all laterals closely to one joins.

Orchard House.—Admit a little air early in the day, but allow
the temperature to rise to 75°, or even to 80°, closing or reducing
the ventilation early so as to enclose as much heat as practicable.
Employ no more water than is necessary to keep the foliage in
good condition, and the less of it in the atmosphere the better,
but insects must be kept in check by an occasional syringing.
Stop any strong growths closely, or remove them altogether, as
they will appropriate more than their share of nutriment, besides
retarding the ripening of the fruit and wood.

The following annuals should be sown without delay:—Collinsias, Candytufts, Bartonias, Asperula azurea setosa, Each scholtzias, Kaulfussia, Limnanthes, Nemophilas, Silenes, Whitlavia, Virginian Stock, Saponaria, Platystemon, Lupinus nanus, Lasthenia, Gilia tricolor and vars., Eucharidium, Erysimum, Clarkia pulchella vars., and Sweet Alyssum. They may be sown in sheltered borders and transplanted in spring. They will in ordinary seasons afford a fine display in spring or early summer Herbaceous plants are becoming seedy, and should have all dead stems or stalks removed, securing autumn-flowering Asters and Chrysanthemums against winds by staking and tying. Anemone

vitifolia alba is one of the finest late summer and antumn-flowering plants, and should have a place in every garden; also Sedum Telephium purpureum. Solidago altissima, and Tritomas are fine for autumn. Roses will be the better for the removal of decayed or bad flowers, and the shortening of irregular growths. Cuttings of well-ripened wood will strike freely inserted in sandy soil at the north side of a wall or fence. Stocks recently budded should be examined, the ligature loosened or removed as may be necessary. Tea-scented Roses trained to walls should be stimulated by frequent supplies of liquid manure to enable them to perfect good blooms, as they will for some considerable time yet if not allowed to lack moisture at the roots. For a supply of blooms for cutting in early spring the old Banksians are unrivalled, but they are seldom seen producing flowers freely, which is chiefly due to the wood not being sufficiently ripened. They flower on the short medium-sized wood; any that is gross or shows a tendency to grow more than a foot in length should be cut out. The propagation of bedding plants should be brought to a close as soon as possible, so as to obtain well-rooted cuttings before winter. There is yet plenty of time for the propagation of Caleeolarias and Violas. Let the beds and borders be frequently examined for the removal of old flowers, leaves, and irregularities of growth. The grass grows thick and fast, and should be mowed and rolled frequently, so as to secure a good solid green sward for the winter. If the walks are in the least worn give a sprinkling of fresh gravel after hoeing up the weeds, and rake and roll thoroughly, as a walk to be agreeable must be clean and dry. If the walks cannot be broken up a few pots of salt water applied during sunny days will destroy the weeds and save much time and labour in hand-weeding. PLANT HOUSES.

Stove.—Tuberous-rooted Gesneras, Gloxinias, and Caladiums as they commence ripening should have water gradually withheld, but do not place them in a lower temperature to stop their growth and starve them into rest. Meyenia erects is one of the finest of stove plants with violet or purple flowers, and continues in flower for a longer time than many, even all through the summer until late in autumn if well supplied with water and liquid manure. It is deciduous or nearly so, and requires to be kept dry in winter. Bongainvilleas that flowered in early summer will now be in fine condition, also Clerodendron Balfourianum, and they should be well supplied with water until the flowering is past, when they must be assigned a light airy situation. Allamandas and Ixoras that were started late will naturally continue blooming the longest; they should be placed at the warmest end of the stove. Acalypha Macafeeana, A. macrophylla, A. marginata, and A. musaica are fine for decorative purposes when about a foot high; the foliage is broad with a metallic lustre, and the plants grow freely in a rather moist stove. Cuttings strike freely in gentle heat in a compost of loam with a third of leaf soil and sand. Torenia Bailloni keeps on flowering through the winter, and for its distinctness is well worth a place in every collection however small. It strikes freely from cuttings inserted in heat, and flowers when in quite a small state. The atmosphere of the stove may now be rather drier than usual. Blinds should be dispensed with, except for the fine-foliage plants. The house should have a thorough cleaning both inside and out. The temperature must be maintained at 65° at night, and 70° to 75° in the day by artificial means, up to 80° or 85° with sun.

Orchids.—A warm moist atmosphere must be maintained, and every encouragement given to such plants as Aërides, Phalsenopsis, Saccolabiums, and Vandas. The blocks, baskets, and pots must be damped over in the morning, and in the afternoon of fine days a sprinkling overhead will be beneficial, care being exercised not to render the sphagnum or peat too wet. The shading must only be employed to prevent the sun scorching the foliage. The temperature of the East India house may range from 75° to 85° by day until the end of the month, when a gradual reduction must be made. Shading on the Cattleya house should be dispensed with altogether, the glass being cleaned to afford all the light possible, as it is important to have the plants well ripened before the winter. All pseudobulbous plants which have completed their growth should have an increased amount of air and be fully exposed to the sun, such as Lælia albida, L. acuminata, L. majalis, and Cattleya citrina. Keep Lælia purpurata and Cattleya Mossiæ in the warmest part of the house to enable them to complete their growth as soon as possible. Calanthe vestita and C. Veitchii may have weak liquid manure so as to encourage them to make large bulbe, as the stronger they are the finer will be the spikes of bloom. They should also have plenty of light, as the principal thing an Orchid grower will now have to keep in view is to have the bulb and leaves well matured before the dull short days set in, which can only be done by exposing the plants to as much light or sun as they can bear. Any Odontoglossums that started late into growth and require larger pots may still be attended to, disturbing the roots as little as possible.

TRADE CATALOGUES RECEIVED.

T. Bunyard & Sons, Maidstone Kent.—Catalogues of Bulbs Roses, and Fruit Trees.

J. George Hill, Crewkerne and Yeovil, Somerset.—Catalogues of Bulbs and Fruit Trees.

Francis & Arthur Dickson & Sons, Chester.—Catalogue of Bulbs.

TO CORRESPONDENTS.

*** All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

BOOKS (L. Shuldham).—We do not know of a more practical work on Orchida published at a moderate price than Mr. B. S. Williams's "Orchid Grower's Manual." Mr. Williams also publishes a work on stove and greenbouse plant that may suit you. They can be had from the Victonia and Paradisc Nurseries, Holloway, London, price 5s. each, post free 5s. 6d.

REMOVING BUDDED BRIARS (Inquirer).—They will transplant safely in November provided you keep the roots moist in transit to your new garden; but the buds will probably not make such strong growth nor produce such fine blooms the first year as if the Briars had not been removed.

ACHIMENES AFTER FLOWERING (Amaleur).—Water should not be withheld entirely so long as the foliage remains green, but it may be given in less quantities after the flowers fade. Too often these plants are much neglected at this period of the year by being crowded under stages where they can have little chance of forming and maturing fue tubers. The plants should have light and air with sufficient water to keep the foliage fresh as long as possible. The tubers may remain in the soil during the winter, the pots being placed in a house or shed where the temperature is not below 45°.

SEEDLING RASPBERRY (Amateur).—The paper box in which the fruiting spray was posted was quite flattened in transit, and all that arrived of the fruit was a mass of pulp.

CLETHRA ARBORRA (Peer Dick).—If you cannot find this plant in the lists of local nurserymen you will find it by referring to the catalogues of such firms as Messrs. Veitoh, Cheleas: Williams, Holloway; and Henderson, Pine Apple Nursery, London, all of whom offer it at a moderate price.

POTTING SHED (An Irish Subertiber).—Not knowing the extent of the ground nor your locality we cannot furnish you with a specification. Apply to three or four builders, and select the plan that you prefer from the specifications they furnish.

BOUQUET-NOSEGAY (Ignoromus).—The terms are synonymous; they are applicable to a few combined sweet-smelling flowers.

PAINT FOR GARDEN STRUCTURES (F. J.).—The paint you name is good for outside work but is too rough for the stages, &c., inside the houses, as they cannot be washed so quickly and cleanly as when painted with smooth lead paint. Paint made of the best white lead and off is equally good for outside work, and is not excelled by other paints for the same purpose.

ROMAN HYACINTHS (A. L. D.).—You cannot obtain the bulbs too soon. They may be potted in the same kind of soil as that employed for other Hyacinths, and be plunged similarly until the pots are filled with roots, when they may be placed on a shelf in a moderately heated house, when flowers will be preduced in November which are very valuable for cutting. You may place five or six bulbs in a 5-inch pot.

BLUE NEMOPHILA FOR SPRING (A. Lady).—Sow the seed at once in shallow drills a foot apart in an open position in the garden; sow rather thinly and cover the seed lightly with fine soil. The seed bed should not be near any vegetable crops which afford harbour for slugs, that eat the young Nemophila plants with great relish. When the plants are large enough to be handled thin them out so that each plant stands singly, when they will assume a sturdy habit and endure frost much better than if crowded thickly together in the rows.

CATERPILLAR ON ROSE (*Biccpa*).—The specimen reached us alive and well; it is the caterpillar of the Peppered Moth (Amphydasis Betularia), one that is apt to vary much in colour. Like other Geometers it is found of putting itself in a stick-like attitude, perhaps thus escaping birds. The food is various, usually such trees as the Acacha, Birch, Lime, Oak, but individuals accidentally dislodged by the wind will settle on shrubs that many be near, especially of the Rosaceous order.

HARDY CLEMATISES (Apricola).—Besides C. Jackmanni the following are good summer and autumn-blooming varieties: "Prince of Wales, purplish puce; Rubella, claret purple; Star of India, reddish blum; Mrs. James Bateman, pale lavender; and Lady Bovill, greyish blue. As a white Miss Bateman is good, but it flowers earlier than the preceding. If you procure strong plants in pots you may plant them now in deep well-pulverised and fertile end

MULCHING STRAWBERRIES (J. E.).—It is not necessary to mulch the young Strawberry bed now, but a covering of rich manure placed on the ground about November, not packing it too closely round the plants, is generally beneficial. Stir the soil as you propose, and apply liquid manure if the soil is not rich. We have not tried supporting the fruit on wires, but have adopted string and stakes, also Birch sprays, with beneficial results during a wet season. During a hot and dry season there is little or no advantage in elevating the fruit above the foliage. Mr. Peach is such a careful and good cultivator that you will not err in carrying out his recommendations. The varieties you have planted are good.

SALTING ASPARGUS BYDS. (M. M.).—It be sed is attended and we would be such as the season of the season of the season of the season.

mencations. The varieties you have planted are good.

SALTING ASPARAGUS BEDS (M. M.).— If the soil is strong and wet we do not think that salt applied now would be beneficial, but if light and of a dry nature a sprinkling of salt will do no harm and may do good. The best time for applying salt is early in the spring, just before the Asparagus heads make their appearance and when the seed of annual weeds is germinating. The salt will destroy the weeds. Another good dressing given a month after the first will keep the beds free from weeds during the season, and the Asparagus will be much benefited. It is deplorable to see Asparagus beds in gardens so crowded with weeds when it is so easy to prevent them by timely and sufficient applications of salt before the weeds are established.

FREAKS OF ROSE GROWTH (T. Brook).—The specimen is another instance of teratology, but no doubt it is due to the same cause that we before suggested, although in this case the flower was a little more advanced in formation before the fasciated stem bearing the two buds was produced.

We could trace the rudiments of stamens and carpels in this instance, and they were entirely absent from the specimen you previously sent.

SEEDLING ZONAL PELARGONIUM (G. W. G.).—The foliage is very fine, round, stopt in texture, and with a well-defined zone. The flower truss is also fine, and the colour of the flowers clear bright scarlet. We are unable to judge of their quality, as for the want of a drop or two of gum nearly all the petals had fallen; the variety, however appears a promising one and worthy of preservation, but does not surpass the best varieties in commerce.

VINES UNHEALTHY (Lancater).—Defective root-action is the primary cause of the condition of the Vines, but the scorching of the foliage has no doubt impaired the colour of the Grapes. The remedy is to produce surfaceroots. Give the border a heavy dressing of rich manure now, and if this kept moist, and the roots of the Vines are already near the surface, it will become permeated with active feeding roots. The Vines will then produce foliage storter in texture than the leaves you have sent, and will not be so liable to be scorched. Train the laterals thinly, and if the spurs are old and imaginately train up young growths from the base and gradually remore the eld spurs and rods as the younger canes become large enough to replace them. If you can produce a mass of surface roots and encourage the production of young wood, so thinly disposed that it becomes well matured, you will obtain much better Grapes than you have now, and which will colour well if the Vines are not overcropped. We do not know whether wooldee eat the roots of Vines; we know they eat the roots of Orchids. They est also Mushrooms and various fruits—indeed scarcely any vegetable food comes amiss to them. You may entrap them by placing boiled potatoes in small flower pots, covering the baits with hay, and laying the pots on their sides where the insects abound. If these pots are examined daily and the woollice found are destroyed they will soon become less minerous, and by perseverance may be almost eradicated.

Wellingtonia Gigantes Coning (J. S. G.).—It has produced comes in

WELLINGTONIA GIGANTEA CONING (J. S. G.).—It has produced cones in many places, and we have heard that home-grown seeds have been known to show symptoms of germination, but that they never produced seedling plants.

THE PEACH AND NECTARINE (Jimes Turner).—The Nectarine is merely a variety of the Peach (Amygdalus persica), and instances have occurred where Nectarines have been produced on the branche- of fruit trees. The Nectarine is named on account of its smooth skin Amygdalus persica leris.

PORTABLE HOT-WATER APPARATUS (R.J.H.).—We have not seen a good stove to be heated with gas or oil, with hot-water pipes attached such a you appear to require—namely, an apparatus suitable for heating a small greenhouse in winter, and removal during the summer mouths. An efficient and economical apparatus of the kind indicated would if advertised probably meet with a ready sale.

MAKING ASPARAGUS BEDS (A. L.).—Asparagus does not thrive well in clay soil, and yeu can only have good bels by employing large quantities of rough sand, coarse grit, and ashes, also incorporating as much as possible of decayed vegetable refuse, leaves, and manure with the strong soil of your garden. The soil should be dug deeply and thrown into ridges, these ridge-being broken and turned frequently during frosty weather, and in the spring level the ground and work-in the additions named. The beds in such soil should be raised well above the level of the ground. If they are 4 feet wife three rows may be planted in each bed, but beds 3 feet wide with two rows in a bed would perhaps be preferable in your case. The planting should be done just as the crowns are commencing growing in the spring, covering the roots with light compost. You can either raise your own plants by sowing seed or purchase stronger plants; both seed and plants can be had from nurserymen. It is not advisable to erop Vine borders, but a few rows of annuals near the margin of the border night not do any harm to the Viess.

PROPAGATING PHLOX DRUMMONDI (A. L. S.).—You have been rightly informed that the "cuttings will strike the same as Petanias," but the plants are not so good as those raised from seed, and a great per-centage of them usually die in the winter. If you require early flowers you may try sowing the seed now, wintering the plants in pots on a shelf in a very light house. These plants, if kept sturdy and are well grown, will prove very useful for cutting from in the early summer mouths.

WINTER CUCUMBERS (M. D.).—You had better obtain plants that are now established in 48-sized pots, as plants raised from seed sown at the present time would not have time to make strong growth before winter. If the trellis can be pretty well covered with growth made under the indusco of light and sun it will be much more fruitful in character, and will be better able to resist insect attacks than growth that is made during the shorter days and longer nights of autumn. It is extremely injudicious to crop to any material extent Cucumbers in the autumn that are intended for producing fruit in the winter.

FIGS IMPORTED (L.).—The value of the imports varies considerably. Thus the value of Figs imported from Italy in 1872 was £20,723, while in 1876 the value of the imports was only £6892; and the Spanish imports, which are about of the same value, are subject to the same fluctuations. The value of Figs and Rasins imported from Turkey in 1875 was £630.614 fy you send 34.61 in postage stamps to the publisher and ask him to send No. 884 the number of the Journal you require will be posted to you.

CONFERS FOR SCREEN (D. F.).—Probably the American Arbor Vitas (Thuja occidentalis) would be suitable, as it is quick in growth and good-sized specimens can be purchased at moderate cost. (upressus Lawsoniana would also be suitable, as also would Thuja Lobbi. We do not know of a better berry-bearing evergreen for covering a wall than Cratagus Pyracantha. The Pinks to which you refer those well in the small pots, but you may shift them if you prefer into larger when they spindle for flowering.

TRANSPLANTING ROSES IN SEPTEMBER (Midland Counties).—As you must either dig up the Roses on the 29th inst. and chance their succeeding afterwards or leave them behind we should certainly choose the former alternative. The day before digging them up cut off a great portion of the summer's growth—that is, shorten all strong shoots and thin out such wood that is not wanted for next year's growth and bloom, and also cut off a great portion of the foliage (not tearing it off, which might in jure the bark or buds) so as to lessen evaporation of the tree's juices. Have plenty of we straw or hay in realiness, and in this envelope the roots, and if the tops can be kept moist also so much the better. On arrival at your new garden lay them in by the heels carefully, covering the roots on a shaded borde, and water and sprinkle them frequently, and plant them in their permanent positions any time after October. By adopting this practice you may save nearly or quite all your Roses.

MIGNORETTE FOR SPRING FLOWERING (M. D., Surrey).—If seed is sown now and the plants are well managed they will be very valuable for decorative purposes in late spring. Clean well-drained 8-inch pots should be employed, the soil—tury loam with a little charcoal or line rubbish and much decomposed manure—being pressed into the pots very firmly, almost hard. Fow the seed thinly, and subsequently thin out the plants, leaving about half a dozen in each pot. Water must be given with great care, and less of it will be necessary fif the pots can be plunged in ashes. A very light frame or pit on the south side of a heated plant structure or forcing house is a suitable place for wintering Mignonette, employing such protection as may be necessary during severe weather. may be neces ary during severe weather.

GRAPES SCALDED AND RUSTED (One in the North) .-- The Grapes are good and well flavoured, but are quite unpresentable at table. Various causes contribute to produce what is known as rusting of the berries; but in this instance there can be little doubt that at some time when the Grapes were young, it may have been on a Sunday morning, the house has been left were young, it may have been on a Sunday morning, the house has been left closed until the temperature was too high and the ventilators have been thrown open somewhat widely to reduce it, and the ontward rush of warm air and the sudden and excessive evaporation from the berries injured the then tender cuticle

then tender cuticle.

NAMES OF PLANTS (R. P. O.).—Habrothamnus fascicularis. (W. P.).—
The finely divided frond is Chellanthes Borsigiana; the other is Polypodium longissimum. (W. D. H.).—The pink flower is Godetia Witneyi, the other is Inula Conyza (C. S.).—Cimicituga serpentaria. (G. H.).—Populius alba. (A. C.).—1, Spirea callosa; 2, Rhus species; 3, Sambucus Ebulus; 4, Sanguisorba canadensis; 5, Erica vagans; 6, Hypericum perforatum. (M. M.).—The white flower is Achillea Ptarmica fi, pl.: the yellow one Solidago rigida. (G. Cre).—The plant you know as Weebis is Senecio Jacobra, the common Ragwort. In Lancashire it is called Kettledock, a corruption perobably of Castie Dock. (A. A.).—1, Gasteria verrucoas; 3 is a Calanthe, probably C. veratrifolia. (Cran/ordian).—Gnaphalium lanatum.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE SUMMER GRAZING OF SHEEP.

WE have on various occasions in these columns referred to the plans of feeding sheep in the summer months under the varying circumstances applicable to the best known systems of sheep management, except that of feeding them upon grass only or nearly so, and our present subject will therefore relate principally to the feeding and fatting of sheep upon pastures or field grasses. We have in various districts of the kingdom grass land sufficiently rich to feed bullocks fit for the butcher without any other food but the grass, and in such cases sheep are often part of the stock; but they are rarely used for feeding sheep alone for the butcher, the bullocks being found more profitable than sheep upon such pastures. There are, however, to be found in almost every county pastures not capable of feeding bullocks without assistance, and which may be called second-rate grass lands, yet they are equal to feeding sheep for the butcher, and more particularly is this the case with certain breeds of sheep The various breeds of Downs and other short-woolled sheep can seldom be made fat upon grass alone; upon the other hand, the long-woolled sheep, such as the Cotswolds, the Laicesters, Devons, and Lincolns, together with some of the best bred Oxford and Shropshire Downs, will graze-out fit for the butcher upon grass without artificial food, all of these being of a quiet and contented habit and disposition. To illustrate our observations we will introduce an experiment tried several years ago upon some fen lands, whereby Devon long-woolled sheep were placed in pastures in company with some Hampshire Downs. The latter made but slight advance in laying-on flesh, whereas the former gained in weight and quality very quickly, and when the long-wools became ready for the butcher the Hampshires on being weighed had gained but very little. Another lot of Devon Long-wools were placed in the pasture after the first had been sent to be killed, and these also became quite fat and were slaughtered; but still the Hampshires remained and only advanced very slowly, and eventually had to be finished-off by winter feeding. This experiment teaches a lesson which every home farmer should know, that Down sheep do not pay for grazing on rich pastures, and that it is difficult to make them fat enough for market thereon without the aid of cake or other feeding materials.

On some of the driest and sweetest pastures we have noticed, not only in Buckinghamshire but in other midland and western districts, that it is customary to keep the Leicester or Cotswold ewes, and particularly upon farms without any or but very little

winter months upon grass, and in midwinter upon hay only or nearly so. By this system of feeding they seldom suffer much loss at lambing time, which by arrangement takes place in March and April, just in time for the ewes to receive the first bite of grass, and by having a pen occasionally shifted with troughs containing cake and artificial food for the lambs the ewes will give abundance of milk, and make their single lambs fit for market in ten weeks, and the twins at twelve or thirteen weeks old. The ewes of full age after the lambs are gone, having the run of the best and freshest grass, will be ready for slaughter by Michaelmas, for it must be remembered that these long-woolled stock fatten very quickly, and, moreover, if made too fat by extra or winter the market. Upon what may be termed second-rate grass land to which we have just been alluding, it is sometimes the custom to purchase tegs just over a year old of the long-woolled breeds in the months of March or April, and graze them out fit for the butcher con after about the random terms of the contract of the co butcher soon after shear-time, and about the last week in June; and if they have been carefully managed, and particularly if they have had about half a pound of cake or cracked beans per day, they will at the time named be found quite fat enough for summer mutton. Second-rate grass land, too, will bear the improvement resulting from the use of cake, &c. To provide for another flock to feed off after the first has been sold, it is well to try more tega or maiden ewes in good condition about the month of May, so that they may be fed in the same manner as month of May, so that they may be fed in the same manner as just described, and become fit for slaughter in October. The second lot will pay for a pound of cake or beans per day after the lat of September when the nights get longer; they will then be in good saleable condition and be sold out of grass, because we have been alluding to the feeding of pastures where no arable is available for winter feeding. We must now remind the home farmer that in feeding first aughits of cross long the first of the control of the co farmer that in feeding first quality of grass land it often lies flat and is frequently strong land, so that in a wet summer the water does not escape so quickly from the surface as may be desirable. a showery summer the grass would be abundant, rich, and forcing, but it is in such seasons and under such circumstances where but it is in such seasons and under such circumstances where the land is not drained, that sheep frequently take the rot except on salt marshes, and if not killed very shortly after it is discovered they may become unsaleable and perish, as large numbers have done for several years past upon some of the richest grazing land in various districts. It is, therefore, very desirable to a certain extent to anticipate this disease in a wet summer always to have rock salt within reach, and make use of cracked beans as part of the daily food, and take the sheep at night to the highest and driest ground upon the farm. The beans will serve to counteract the effect of a large amount of water will serve to counteract the effect of a large amount of water taken into the system in grass feeding, and if not entirely preventing the disease of the liver, will at any rate make the sheep fit for market earlier and thus evade the injury. It must, however, be quite understood that we do not advise the grazing of sheep upon the best land, because we think bullocks would fatten and pay better, or with only a few sheep grazing with them, say one to a bullock.

We have in this case purposely avoided any allusion to the these pastures are incapable generally of what we call grazing sheep—that is, to make them fat, such lands being adapted only for the feeding of breeding flocks or store sheep. The observations we have been making applied to the long-woolled sheep, and amongst those we have alluded to we intentionally omitted to mention a breed of sheep called the Romney Marsh breed. These are long-woolled and quite distinct from the others named, and for a long series of years had been bred without crossing, with the view of their being enabled to withstand the storms and wind peculiar to the extensive fens and pastures on the south-eastern coast of Kent denominated Romney Marsh. It is nearly on a level with the sea, from which it was reclaimed many centuries ago, and is preserved from encroachment by means of dykes, &c. The native breed of the district were originally large coarse animals, but have lately been extensively crossed with the new Leicesters and greatly improved, and will consequently yield to superior management of feeding. &c. The consequently yield to superior management of feeding, &c. The old system of the Romney breeders was to send their lambs to the farmers on the uplands to be kept during the winter, returning to the marshes to be grazed during the summer; but during late years they have retained their lambs at home and feed them in part with the produce of the arable land where available, and keep them in store condition only until the grass is fit for feeding. Indeed they usually run out daily into the marshes to get a scanty mixture of food whilst receiving roots, &c., in the yards or night pastures. These marshes are almost entirely a grazing district and do not furnish hay of a desirable quality, because close feeding for a long period has destroyed the finest herbage, leaving chiefly hard wiry sorts of grass, unfit for hay and only adapted for grazing whilst young and growing. The fattening quality of the herbage varies very much; but in some of the rich soils, denominated "quick land," requires to be heavily stocked in a favourable ewes, and particularly upon farms without any or but very little season, otherwise the grass gets long and injures the future pasarable land, and these ewes are fed chiefly during the autumn and turage. Some of the best land will carry from five to seven

sheep per acre and make them thoroughly fat. On the highest and weakest pastures breeding flocks are kept, and the lambs reared serve to supply the best pastures with stock. It is rarely that any other sort of sheep are fed on the marshes on account of the climate, as farmers assert that their stock is the only breed which will endure the winter experienced in this marsh district, which extends about fourteen miles by ten. Before quitting the subject we must advise the home farmer never to buy sheep low in condition for grazing on pasture land, and if so circumstanced it is better to breed all they require and feed all they breed. At the time of selling many men of experience will estimate the dead or carcase weight of their sheep very closely, but it is well to have a weighing truck at hand and weigh the animals alive. In that case there is a certain amount of judgment required to estimate the carcase weight as compared with the live weight. It is, however, fair to calculate that a moderately fat sheep will yield 58 per cent. in mutton compared with the live weight, but when the animals are thoroughly fat and when fasted before weighing they will yield 64 or 65 per cent. of mutton and sometimes rather more. In feeding sheep on rich pastures, these animals suffer frequently from foot rot, which unless properly treated at the onset will often prevent them from fattening, particularly in wet summers.

WORK ON THE HOME FARM. Horse Labour. - Horses will be now principally engaged in working the reaping and mowing machines. In a few of the earliest districts the winter oats, peas, early white oats, &c., in districts where the weather has been fine will have been carted to the stack. In some instances in favoured counties a considerable acreage of wheat will have been carted, and more being now nearly or quite ready for stacking, will consequently employ all the horses in the intervals of fine weather. The second crops of clover also must soon be cut, unless it is thought advisable to leave it for seed; and this may be worth while in a late season like the present, for it will lessen the pressure of labour at the busiest time, and clover seed is likely to fetch a good price next year. On the other hand, if the weather should prove fine and the hay can be well made, there will probably be a great demand for it next winter, in consequence of so much hay having been damaged and, in flooded districts, some entirely lost. We have noticed a large quantity of pasture and meadow hay this year which has been so much damaged that it is a question whether it should be got up as hay at all, as the expenses attending it must have been very heavy and the value not equal to well-saved straw, even when it has been carted dry. There is, however, an alternative when it has been carted dry. There is, nowever, an alternative adopted by some farmers in case the hay is seriously damaged—that of spreading it on the land for manure; in fact, we know farmers who, if they get a light cut of grass, often spread it over the land, allow it to settle down on the surface, when the worms will draw it into the land, and this plan is adopted instead of using manure in the ordinary way. This system, however, would not answer upon irrigated meadows or fertile pasture, not only because the land does not require to be manured, but also because the bulk of the grass when cut for hay would be too great if the bulk of the grass when cut for hay would be too great if spread to sink into the ground properly, and would moreover impede the second or autumn growth. It must be after all a question of policy, reckoning expenses on the one band and its value for manure on the other hand. The odd horse or horses should at all possible intervals be employed in the interculture of root crops, for in many districts it has been quite impossible to

keep the crops whilst young properly hoed and cleaned, or even singled out in many instances, and where this was the case at the commencement of harvest the labour of either men or horses could not be spared conveniently for such work.

Hand Labour.—All will now be chiefly employed in harvest work, and it is particularly desirable that the ricks of corn and pulse should be thatched immediately they are made, as a sudden thunderstorm will greatly damage an open rick. This work may be easily done if the straw, as recommended by us for several weeks past, has been drawn and piled ready for use. Every farmer, however, ought to have a thatcher always ready upon the farm, and not trust to thatchers, who often pass from farm to farm and do the thatching at their own convenience. We have induced many men in our time to learn thatching work, and they have proved advantageous to the home farmer and to themselves by earning good wages. As fast as the corn is cut the grass on the banks and borders may be cut the second time, the first cutting having hear removad and dispensed of in the menths of May and having been removed and disposed of in the months of May and June. We were speaking with a farmer a few days ago who occupies about three hundred or four hundred acres of arable land chiefly, and to whom we recommended this plan of cutting the grass, weeds, &c., on the banks and borders of the fields, and he informed us that during the whole summer since he left root-feeding that he has fed twenty-five Shorthorn dairy cows with feeding that he has fed twenty-five Shorthorn dairy cows with produce of the borders only as green fodder, allowing them in addition 4 ibs. of cake each per day, and that he has sent all the milk to the metropolis, and has had an abundant quantity up to the present time. We note that the barley crop this year is much overgrown with clover where it was seeded in the apring. Now this is not only very much against the harvesting of this crop, but

also very injurious to the barley whilst growing, for the clover competes so strongly with the barley as to reduce what would otherwise prove a plump sample, fit for malting, to a thin light grain only useful for grinding into meal for feeding purposes. We have seen many fields of barley this year cut and carried to stack the same day in good condition where the barley had been sown after wheat; but this could not have been done if clover seed had been sown in the barley.

seed had been sown in the barley.

Trifolium should be sown on the first opportunity, and we advise the home farmer this year to plough the land instead of sowing on the stubbles and working in the seed. When, however, the land is ploughed it should be pressed, also heavily rolled twice over with the ring roller, and sown after the roller, as the seed then falls into the little channels made by the rings of the roller, and it is then not only easily buried by harrowing by the chain harrow but it finds a tolerably firm bottom to root in, so desirable in the cultivation of trifolium. desirable in the cultivation of trifolium.

POULTRY FARMING.-No. 6.

WE proceed to give a few more hints on the establishment and management of poultry on a large scale, which we failed to compress into our last article.

1, As to commencing poultry keeping. We should advise a beginner not to start with anything like the number of laying hens that he intends eventually to keep. All the runs destined for breeding birds, or nearly all of them, may be filled up; but as we recommend that none but pure-bred birds be purchased for laying, it would be too costly to start with an entire stock of these bought at 5s. or more each; even if it were wise to launch these bought at be. or more each; even it it were wise to launch out at once on so large a scale the greater part of the stock must be home-bred. Those which are required at once must be procured from breeders of high-pedigree stock; they nearly always have plenty to part with at moderate prices, deficient in some trifling points of form or feather. This is the real use of breeding high-class stock—viz., that the yards of the many are improved that the proceeding the process of the control of the form of the feather. high-class stock—viz., that the yards of the many are improved by the fancy and labour of the few. Cross-bred birds are ex-tremely useful in their way, but they should be home-bred. Even after the establishment is in working order the pullets of kinds specially required for laying, but which are not good for the table, should still be bought annually—e.g., Brahmas and Cochins. Every theory as to distinguishing between those eggs which will produce cocks and those which will produce hens has been proved abourd by repeated experiments; there is therefore no method of controlling the product, and the rearing of a number of cockerels

unsuited to the poulterer would be a loss.

2. On the special management of the laying stock there are a few things to be said. Those who have written on poultry as farm stock, and who have calculated, erroneously as we think, that enormous profits are with little difficulty to be made by the occupation, generally advise that all the laying pullets should be killed at the end of their first laying season. There is something to be said in favour of this system—viz., that all expense of keeping birds through the unproductive moulting season is thereby saved, and that the hens are killed at a stage when they are far

more edible than they will ever be again. In spite of these arguments we recommend that they be kept through two seasons. We have always found hens lay quite as many eggs in their second season as in their first, and much larger. The difficulty, too, of finding a good market for two-year-old birds, strange though it may seem, is not at all great. In many places thou-sands of such are bought up at farms for large establishments. We have vivid recollections of the never-failing supply of "fowls" in our own University, which were evidently of this class, and we hear that in our neighbourhood the farmers' wives find a readier market for such birds, and even much older ones, than for spring chickens, for the supply of a military college. We have often in chickens, for the supply of a military college. We have often in articles on the management of breeding stock inveighed strongly against the use of heating foods. Such observations, however, do not apply to hens kept solely for laying, and destined to have but a short career; from these the great object is to get as many eggs a snort career; from these the great object is to get as many eggs as possible in their two years, and we should through all cold bad weather mix Spratt's patent food, according to the directions we have frequently given, with their other food. Those of the sitting kinds which we do not require for rearing autumn chickens we should leave on the nest a fortnight if they become broody, as probably all will in August or September. The rest causes a rapid moult the hird recovers for scorer and less much better in rapid moult, the bird recovers far sooner, and lays much better in the winter than if it were kept laying by artificial means. As we have before said, an observing and intelligent person will discover if the said of the sa

and move all such into the superior order of breeders.

3. The general management of the breeding stock should be such as we have often prescribed for well-bred poultry. In the first instance a far more liberal price must be given for them than for those which are looked upon solely as egg-making machines.

When hens show recombing morning as Larger and producers of fine When hens show peculiar merits as layers or producers of fine stock they may be kept through a third season, mated with robust cockerels; we should not advise any but Game cocks ever being kept over two years. All breeders and layers alike must have

discover if any of these hens show peculiar excellence as layers,

abundance of mortar or bricklayers' rubbish. When hens are kept in small numbers and at complete liberty they procure for themselves by diligent search the necessary materials for the formation of eggshell; when they are in large numbers or at all confined these substances are soon exhausted, and the supply of eggs depends much upon their being provided. Any observer of poultry will have seen the distressed craving with which a laying hen in confinement rushes at broken crockery or a crumbling wall. Those confinement rushes at broken crockery or a crumbling wall. Those continental regions from which the largest supply of eggs comes have almost always soils rich in calcareous matters.

4, On the rearing of chickens for the market on a large scale volumes might be written. We can here only attempt to give a to the headings of points on which an inquirer should take pains to inform himself well, and refer generally to many articles on chickens through their various stages, which have appeared in our columns as the seasons came round. Those who rear poultry for the consumption of their own household are generally content with chickens through the greater part of the year; a breeder for the market must have them ready all the year round, so as never to fail his customers. Of course those reared during the inclement seasons cost more in time, trouble, food, and losses of a portion of them before they are fit to kill their spring and summer chickens, but the extra expense is well repaid by the high prices they fetch. For autumn and winter setting we recommend the eggs from a first cross in preference to those from the pure-bred stock, the chickens are more vigorous and are fit for the table much sooner. We have always observed that the produce of crosses grow quicker in their early days; that of pure-bred stock continues to grow much longer. The latter are therefore best suited for fattening up to enormous size when six or eight months old, the former for killing at from eight to sixteen weeks old. The intending poultry keeper should not fail theroughly to study the comparative merits of the many incubators and artificial mothers now offered to the public. Those heated by hot water and not by lamps seem by far the most easy of management and less apt to fail through accidents. We have not yet had the opportunity of trying any of the most modern incubators, but hear on all sides of astonishing success with Christy's. It would be well worth while, however, to try several, and carefully to compare the results before attempting a poultry farm. The time, and trouble too, saved by artificial mothers must be immense. We should recommend one to hold mothers must be immense. We should recommend one to hold about eighty chickens. One of the acre runs would accommodate these till they were fit to kill, or the pullets which we may roughly estimate at half the number, for some months after the cockerels were killed off. Directly the run is emptied it should be well limed if of grass, and left vacant till the grass grows strongly again, or immediately dug over if intended for the cultivation of vegetables.

On the food of chickens we have before written much. We have always found the flesh of those reared chiefly upon ground cats, such as is used in Sussex, the best. Ducks by no means cats such as is used in Sussex, the best. Ducks by no means require such delicate fare as chickens, but the whole method of rearing them is so different that we will soon devote a separate article to them. We believe that the best information on the preparation of first-rate table poultry is only to be procured in France. The exact time necessary for the fatting of birds of different ages, the changes of diet during the process, the advisability and method of caponising, would be better learnt in some such establishment as that at Gambois near Houdan than in any English yard, and a visit to some of the great French breeders would not only pay well but be absolutely necessary for any would-be large cultivator

of poultry in England.

We have described some of the difficulties and risks of wholesale poultry breeding. We have shown to the best of our powers how far they are in our opinion surmountable or avoidable. We repeat what we said before, that we believe no attempt at poultry farming on intelligible principles has been fairly made in England, and we should much like to see one so made.—C.

VARIETIES.

At the Council Meeting of the Bath and West of England Society and Southern Counties Association held at the Grand Hotel, Bristol. Sir J. W. Walrond, Bart., in the chair, the report of the Committee appointed to take into consideration the Society's relations with county local associations in its districts, with a view to a uniform system of co-operation with them recommended amongst other proposals that the exhibitions of the Society be so distributed as to insure, as far as possible, a regular and general diffusion of their advantages. On the motion of Colonel Luttrell, Chairman of the Stock Prize Sheet Committee. the sum of £2070 was granted for prizes for stock at Worcester in 1880, being the same amount as at Exeter. Mr. R. H. Bush, as Steward of Poultry, obtained the sum of £225 for prizes in his department at Worcester; and votes for Music, Horticulture, and Art Union were, on the motion of the respective Stewards, granted on the same scale as at the Exeter meeting. A communication was read from the Tunbridge Wells Farmers' Club, asking whether the Society would be inclined to entertain an invitation from the neighbourhood for the meeting of 1881, and the Secretary was

directed to reply that the invitation had been favourably received by the Council, but no conclusion could be arrived at until they were satisfied that the various requirements of the Society as to the site and other matters could be complied with.

THE Cottage Garden Show held at Great Hadham, the pretty rectory grounds, by the kindness of the Rev. Dr. Gifford, was highly successful through the efforts of its enthusiastic Secretary, Mr. C. Gayton; so much so as regards honey, that the Rev. Herbert Peel remarked in his speech at the prizetaking that the collection of honey was better than any he had previously seen during 1879. In supers both first and second prizes fell to Miss Gayton, the Secretary's sister, who seems to be the apostle of advanced apiculture for the district. In run or the apostic or advanced appointure for the district. In run or extracted honey the competition was keen, eleven entries being made, and it is curious that the Judges accurately separated the extract d from the run in each case. In competing skeps the prize frame hive fell to a very good specimen weighing 87; bbs. Manipulations were carried on in the tent during the afternoon.

THE Mark Lane Express refers as follows to the harvest and the crops:—"In Scotland many of the fields are still quite green, a precarious state of affairs which causes agriculturists green, a precarrous state of analis which causes agriculturings much anxiety, as, even if the days prove fairly dry, the ripening power of the sun is rapidly diminished as autumn progresses. Both wheat and barley will prove exceptionally deficient in point of yield; but the continuance of dry sunny weather may do something to improve quality and condition, and a fair crop of straw will probably be secured, which is a matter of importance to stock owners, seeing how much of the hay has been lost. Potatoes have suffered from disease more or less throughout the kingdom, a recent advice from the midland counties stating that many acres have been ploughed in, so that this valued esculent may be considered to have disappeared from its place in the list of the season's crops. Mangolds, Swedes, and turnips have improved slightly during the past few days of fine weather; but the root crops generally are backward, foul, and unpromising."

THE Incubator Tournament at Hemel Hempstead, in

connection with the Poultry and Pigeon Show to be held on October 1st and 2nd, commenced on Tuesday. The conditions of the last year's competition of incubators were that one person without experience should take charge of and work all the machines entered, so as to determine which was the simplest and best adapted for use by the uninitiated. The result was in favour of Mr. Thos. Christy's machines, which took first and second prizes. This year the conditions are that each machine shall be worked by an expert under the strict personal supervision of the Committee. Seven incubators in all are entered under these conditions, and on Tuesday morning the Committee proceeded to mark the eggs, which was done by assigning to each member the eggs intended for one incubator, the member writing in ink his name intended for one incubator, the member writing in ink his name and the number upon each egg; this to prevent mixing, loss, or replacing. The eggs were then placed in the incubators at twelve o'clock precisely, and the competition commenced, to extend until October 1st—the regulation three weeks—science not having been able yet to shorten the work of Nature in this respect. The machines entered are those of Messrs. Christy's, Howell's, Cashmore's, and Watson's. Twice a day the exhibitors have access to the machines under supervision of the Committee and the results. the machines, under supervision of the Committee, and the results are being awaited with interest. No entries for Pigeons and poultry will be received that are not posted on Saturday next.

PRESENT MANAGEMENT OF APIARY—UNITING STOCKS-QUEENLESS HIVES.

THE low temperature of the now bygone summer has prevented the formation of saccharine matter in plants in its usual amount, while wet has too constantly prevented the poor bee from gathering the little honey secreted. The past unfavourable season besides has been a successor to a severe protracted winter which had exhausted both bees and their stores. As a result it is much to be feared that immense numbers of stocks in the hands of the less careful or less instructed will die during the period of cold, which is already warning us of its approach. The remedies to be applied in the present bad condition of things are principally two—uniting and feeding; upon the former of these let me now say a few words.

Uniting Stocks.-As experience grows so, I think all advanced bee-keepers will admit the value of that golden rule of api-culture, "Keep your stocks strong," is more clearly seen. There is no mistake which is occasioning so many losses and which is hindering so much the productiveness of small apiaries as that of looking to results rather in the number of stocks than in their condition. That a few bees may by attention and feeding be worked into strong colonies when the spring is with us is indeed true, but at this advanced period of the year to hold to little weak stocks because they can be counted as stocks is to court disaster. Not only should we unite the very poor and weak, but we should satisfy ourselves that our hives all contain fertile queens, for the production of which this year has been most adverse, my experience being beyond precedent disappointing,

failures actually exceeding the number of successes. With frame hives a simple inspection will be sufficient; nor need the queen be actually seen, the presence of worker brood, the sealing of which, be it remembered, is nearly flat, being itself sufficient evidence of the presence of an impregnated mother. Brood sealed with very prominent convex caps, if it be in worker cells, will proclaim, however, a drone-breeding queen or a fertile worker, and steps will have to be taken to cure the evil. This calls for a word on

Queenless Hives.—The absence of queens will be now, as in most cases, indicated by the presence of drones, for queenless stocks do not on the failure of honey, like others, kill these, to them, useless consumers. No queen being present brood and eggs will not be found, and such should be set aside for uniting. With skeps the examination can hardly extend beyond puffing smoke into the entrance and then inverting. More smoke, and drawing the combs gently apart, will enable us to determine whether sealed brood is present, while the weight must decide as to the amount of honey contained. Having determined which stocks are to winter and which are to be broken up for strengthening others, we arrange the plan of union. If we are using skeps we should remove by drumming the bees from the broodless hives, adding them to those containing developing young, so that these be not lost; but, catteris paribus, it is wise to elect the skeps in best condition and those with the cleanest combs for standing. These arrangements made, we begin by drawing nearer together daily those stocks that are to become one, or to be married as some say. If many hives are near the removals must be made by small stages, or the bees wiil become confused, enter the wrong hives, and fighting is likely to be the result. When the two are standing side by side we commence operations with the skeps by puffing a little smoke into both. Turning them up we pour over the receding insects a gentle libation of thin syrup (thin, because otherwise it will gum the bees together); if the day be chilly the syrup should be slightly warmed, and as an additional precaution it will be wise to add to it two or three drops of essence of representation; but if the warmen, and as an authors of essence of peppermint; but if the ensuing directions are properly followed success is certain without scenting, which sometimes tends to robbing. The skeps are now placed on their stands for the bees to gorge, and while we are preparing for the drumming we now and again give two or three smart raps on the straw sides of the hive in hand to keep up the terror of those within, and cause the gorging to go on to repletion. We now drive the bees from the broodless hive, not forgetting an occasional rap for the other. When all are up we puff a little more smoke amongst those to which they are to be anded, invert them, place the skep containing the driven swarm upon them, and by a sharp smack send the evicted bees down headlong amongst the combs. In a minute or two the now empty skep may be removed and the united stock placed, propped up by a stone upon its stool, which should be put midway of the stations the two hives previously occupied. The two cardinal points in this operation, which if observed will never be followed by fighting, are these:—lst, Have both lots of bees subdued and gorged. 2nd, Introduce them to each other in mass so that they are actually mingled before they have time to make an attack. Variations may be made, such as drumming both into one skep and then throwing them down together to enter the selected hive, but this is needlessly tiresome; drumming one with the precaution given being amply sufficient, and more than this not being practicable if one be a swarm of the year.

Uniting bees in frame hives is much less troublesome. The contiguous placing of the colonies by slow marches is, as in the previous case, necessary. The frames ought to be interchangeprevious case, necessary. The frames ought to be interchangeable; if not, in addition to the directions given the brood and what may be worth saving of the combs of one stock must be transferred to the frames of the other. Use smoke and scented syrup as with skeps, and also rap for the same reason the hive sides a queen is possessed by both lots remove the one you think of lesser value, but if you are not expert at finding queens leave the deposition to them. Remove the stock to be broken up some few yards, shut the mouth of the hive to be strengthened, and place it between the two previous stations; put a large flat board against the door of it upon which to jerk the bees. Lift the frames out one by one, shake the bees off at the hive door at which they of course now cannot enter; remove superfluous combs, shake also the bees from other hive amongst the first, and add the brood and other frames till the stock is as fully combed as you intend it to be; shut all up, remove the obstruction to the bees entering, and urge them with more smoke. They will rush in together to agree like brother and brother. For myself I simply frighten and gorge, remove combs not needed, push the frames together in the first hive, and add at once those from the second, and never have a case of fighting.

If no frame hives are found in the apiary the pieces of brood If no frame hives are found in the apiary the pieces of broad which would be otherwise wasted may be placed in a straw cap and held in proper relative position by pieces of cork, and then stood over a hive to hatch out. In this way a stock may be strengthened with young bees to its immense advantage. Frame hivists will know how to value and to utilise this all-important late broad. The question of feeding must remain till next issue. OUR LETTER BOX.

PREPARING LAND FOR GRASS (G. W. S.).—You had better work and clean the land thoroughly this autumn, leaving it well exposed to the action of frost during the winter; then in fine weather in spring work it again so as to produce as fine a tilth as possible, enrich it with manure, and sow the seeds. The presence of coltefoot indicates that the land requires draining.

SELECTING BREED OF FOWLS (H. S.).—As you wish to breed for home use as well as for market keep Brahma hons and a coloured Dorking cock.

WAXBILLS (A. H.) .- You feed them correctly. We should give the ante-

PROMISE TO PAY (A Twenty-wears Render).—The promise to pay made before a witness was an acknowledgment of the debt, and it is recoverable.

FERDING BEES WITH BARLETSUUAR (H).—The best method of supplying it is at the top of the hives or boxes. Tie a dozen sticks of it together, and, after opening the live at top, place the barleysugar over the opening covering it with a garden pan or flower pot, and just before it is all consumed give a fresh supply in a similar way. When hives cannot be fed at the top the barleysugar may be inserted in the entrance at the bottom of the live.

FOUL BROOD (Carolus).-In our previous reply we stated that although a definite opinion could not be pronounced upon the case by simply examining the combs with the unassisted eye, yet the odour was such as to arouse the combs with the unassisted eye, yet the odour was such as to arous serious suspicion which the uncroscope unhappily confirmed, as the brownish mutter was full of micrococcus. You now tell us that another authority, to whom you submitted a like specimen, auswers, "There is no sign of foul broot." Perhaps not to the superficial observer; but as we carefully went through the case and found tens of thousands of micrococcus germs with the accompanying minute fibrilla, we can only avert our previous position—that the specimen sent was undoubtedly foul broody. If the combs in the brood nest of the hive under remark are examined there can be little difficulty in determining the extent of the disease, which if but slight may be eradicated by the spray-producer and feeding with salicylicated syrup, the honey previously having been removed by the extractor, which we learn by your letter has already been used upon the hive in question and so, we fear, tainted with the disease. It should be very carefully cleansed before healthy combs are put into it. But if the disease has great hold it will be better to take all honey and build the bees up with foundation and feeding in cleaned dition.

WHITE GRUBS IN HIVES (T. B.) .- When bees are on the verge of starvation, instead of continuing to use their spare stores on broad-feeding until all is gone, they consume the eggs already laid and eat up the smallest grubs, is gone. they consume the eggs arready laid and eat up the smallest gruts, proceeding to suck the juices of the larger and carry the residue from the live. They now tear open the cells of the chrysalides, first the drones and afterwants the workers, puncture their bodies, feed on their juices, and carry the "white bees" as they are often called from the hive. White bees about a hive door then are a sign of severest pinching, and the remedy is clearly feeding. Before these "white bees" are seen, however, great nischief has already been worked, as a prolonged check has been put upon the production of roung bees.—E. C. of young bees.-F. C.

of young occs.—r. C. ERADICATING RATS (C. IV.).—In your case as the rats are in a bank we should employ a rateatcher occasionally who has well-trained dogs and ferrets, and more rats would be killed in a day than your man can shoot in a year. You might have a ferret of your own, which if permitted to travere the rat runs once a week would probably cause a great number of rats to seek fresh quarters; but we should first employ a man as recommended, and have as many of the rats killed as possible.

REMARKS.

-Cool slightly misty morning; warm, bright, and sunny day afterwards. Clear moonlight night.

Clear moonlight night.

4th.—Misty autumnal morning, fine and bright from 8 A.M. till 1 P.M.; dull and very cloudy afternoon; fine evening.

5th.—Damp close morning; thue afternoon with little sunshine; fair evening.

6th.—Very thick and dull all day; fog in evening.

7th.—Bright in early morning, overcast from 9 A.M.; showery from 2 P.M. till 4 30 P.M.; bright fine evening. Gusty wind.

8th.—Fine day, at times rather cloudy; clear starlight night.

9th.—Showery day; heavy shower at 1 P.M. and 6 P.M., intervals of bright sunshine during the day; very high gusty wind; cloudy evening and calmer. Clear at night.

Slightly warmer than the previous week, and in fact nearly of the average temperature for the first week of September.—G. J. SYMONS.

COVENT GARDEN MARKET .- SEPTEMBER 10.

THE supply of fruit arriving now is almost entirely from abroad, large quantities of Grapes still reaching us from the Channel Isles, the supply of home group haine area limited. home-grown being very limited.

productions.

VINES IN POTS AT COMBE ABBEY GARDENS.

EADERS of the gardening papers are well aware that Mr. Miller, the gardener at Combe Abbey, is a noted grower of first-class Grapes, and most people when visiting these gardens expect to see good results. During a recent visit I saw as good a crop of Black Hamburghs as anyone could wish—fine large berries, and a regular crop of good-sized bunches, all thoroughly well finished. I think it is generally admitted that to be a successful grower of any one kind of fruit it is always necessary to keep renewing the borders, and at Combe young Vine-planting and replanting is the order of the day. In fact, as in everything else, to be successful a gardener must try every means in his power to keep the plants healthy. No standing still will ever win a gardener much credit for his

In one of the vineries I noticed a fine lot of strong healthy pot Vines, well-ripened plants ready to produce an early crop next year. Mr. Miller told me the eyes were not inserted before April this year! a fact of which he hoped to show me ample proof before I left the vineries. I must admit I was inclined to laugh at such an assertion, seeing the Vines were so healthy and the pots so well filled with roots. I cannot do better than explain the whole operation as nearly as possible in Mr. Miller's own words, merely noting that I never saw better pot Vines even from cut-backs.

"In the spring of 1878 it was necessary for various reasons to replant a vinery. For this purpose I had in the autumn prepared some Vines by laying them on some wattle framework, so that in June, when I purposed planting, I could move them into their places without much disturbance of their roots. The spring of 1878 was cold and wet, so that these Vines made but a poor start, and I did not feel justified in planting the vinery with them as I had intended. I had no other young Vines, and there appeared to me no way out of the difficulty but to purchase the required number of young Vines from a nursery; this for various reasons I was very loth to do. It so happened that during the season of 1877 I had encouraged from near the base of our stronger Vines a number of shoots; these were trained horizontally along the front glass of several of the vineries, and they appeared very strong towards autumn. I had no particular object in growing these shoots in this manner at the time; they might have been fruited along the front, or they might be cut away. It so happened that at pruning time they were left and trained along the front. About the middle of April, when I was in a dilemma to know what to do for Vines to plant my house, these rods were breaking beautifully, and the shoots or laterals, which were very fine, were making straight upwards. After looking at them a time or two rather covetously the idea occurred to me to layer them. For this purpose a number of 10-inch pots were filled with loamy soil and placed in rows under those shoots, which were pegged firmly to the surface of the pots, a handful of loam was then heaped over the base NO. 964-VOL XXXVIL. NEW SERIES.

of the laterals and along the horizontal rods to the extreme edge or tips of the pots. This done, our experiment so far was at an end. We did not have to wait long for the result, for in about a week an abundance of fine white roots were seen protruding from the base of the laterals and along the rods to the extreme edge of the pots. Meantime the growth of the lateral shoots took such a bound that no one except those who had an opportunity of observing would have believed it. I was now satisfied in my own mind that the experiment was a success. Whilst these Vines were so preparing we busied ourselves by replacing the old effete border by a new one, and by the time this operation was finished the Vines layered as described were thoroughly rooted, and, having been for several days cut away from the parent stem, were finally planted in the newly-prepared border; some of them reached beyond the top of the house the same season. In the winter they were cut down to within a foot of the ground; they are now splendid rods quite up to the top of the house, after having been stopped several times. So fruitful were they, although being cut so closely down, all of them would have carried three or four bunches of fruit. Referring to the labels in the pots I find that some of the canes were layered on the 23rd of April and the young Vines cut away on the 25th of May, and others in more or less time. Herewith is a sketch (see fig. 26, page 232), which shows pretty clearly how the operation was performed. The whole affair is so practical and so simple that but little explanation is required. The pot Vines raised in the same way this year are very strong and are now ripening out of doors. I have a few rods prepared this year to yield me a good crop of plants next year.

The pots as shown were placed on a plank to bring them near the glass and keep them level and steady. Time is everything to those who have to produce a great deal from a limited quantity of glass. This system of producing young Vines in a few months is undoubtedly a step in the direction of progress; it may be capable of improvement, but to me it seemed so genuine a system and so simple that I need make no excuse for bringing it under the notice of your readers. Mr. Miller is one of those energetic men who well deserve the thanks of all members of the craft, and if this system which I have tried to lay before your readers has any merit, which I undoubtedly think it has, all

the credit belongs to him. It has occurred to me that this system might be considerably extended by nurserymen and others who grow pot Vines largely every year. Why should they not try a house planted out permanently with Vines and so layer them, and thus secure fine Vines in a few months, instead of having to grow their Vines two years in pots as at present? A crop of Grapes might also be had at the same With these few remarks I will leave the readers of your Journal to think this subject over, and I feel sure the Editors will be pleased to receive any practical remarks on this, to me, most interesting subject—the more extended cultivation of the Grape Vine.—JAMES SMITH, Gardener to the Earl of Rosebery, Mentmore.

[The advantages of Mr. Miller's mode of raising Vines NO. 1616.-VOL. LXII., OLD SERIES.

ROSES.

MANY times during this wet summer as I have wandered in my churchyard, where I have for two years been struggling to make a collection of herbaceous plants, and have seen the miserable bedraggled condition of these plants. "Plenty of cover but no game," as Canon Hole has it in his "Book on Roses;" plenty of foliage but no flowers. As I have gazed with mournful eyes at Irises, Pyrethrums, Potentillas, Helianthemums, herbaceous Asters, Phloxes, and Delphiniums decaying and dying away in the pitiless rain and high winds—as the memory of the large sum of money spent on these plants recurs to me I look for comfort or consolation to another flower-my first love, my earliest friend; and here and there on plants so weak that no nurseryman would send them out from his establishment, bravely fighting against the wind and rain, are blooms of Roses which, if not fit for an exhibition stand at one of the metropolitan shows, can still hold their own at the local ones, there once more comes across my mind the conviction, "After all there is nothing like the Rose." Yes, the Rose is still the "queen of flowers" in my eyes, and as my genial friend and your well-known contributor, the "HEREFORDSHIRE INCUMBENT," says, Whatever hobby I may take up, the Rose and its culture, he is sure will ever be the desire of my heart, so I must and shall ever stick to the Rose. And this year, as if to punish me for my desertion (temporary and enforced indeed it is), the wet summer has demolished all my hopes and upset all my calculations as to having a succession of flowers, while the Rose, which has been neglected, alone has bloomed at all freely.

Reproaches of various kinds and degrees have also been addressed to me, all of which have borne bitter fruit. hear," said a lady, who visited my churchyard, in most re-proachful tones, "I hear, but can hardly believe it, that you have given up growing Roses." I feebly point to five beds de-voted to their culture, but she is not to be appeased. "You used to devote the whole of your churchyard to them, and now have only five beds." The old man who has attended a hundred shows with me looks sad as he cuts the grass on the lawn when the Irises are in bloom. "What do you think of these flowers, Job?" I ask, pointing to some fine English Iris. "Nothing at all, sir. I don't like them a bit. They are here to-day and gone to-morrow." I go away humbled, and find another old faithful servant at work weeding among the Iris barbata, which was then at its full (?) beauty. "I don't know what you think, sir; but I don't care anything about these flowers. There's not much in an Iris. Give me a good Rose," pointing to Alfred Colomb. And now punishment of the most severe kind is administered to me. I may deserve much, but I hardly thought I had merited this. Canon Hole has written a long article on Roses to a newspaper. He mentions all the rosarians of any note, together with their place of abode, from Land's End to John o' Groat's; and he leaves me and my county of Dorset out altogether. Nemesis has indeed overtaken me, and Nemesis of another nature. Queen Ross has punished me in another way, but that a very severe one, for my temporary desertion. If the Canon has chastised me with whips, she has administered to me scorpions. On Sunday night after service, on getting down from the wall of the churchyard on the site of an old Rose bed-the first one I ever made, but which is now carted away—I injured my left knee so severely that I am writing in bed enduring torments, and assured by my doctor that for a week at least I must remain there. The thought of the deserted Rose and my own renegade conduct is a very bitter one, and I suffer so much that even the "PARSON'S GARDENER" would pity me, and the returning officer patch up a peace. And now repentance has come, and, as it always should be, is followed by a good resolution. I must have another try to grow Roses; if not for competition, at least for garden purposes. But what am I to do? What steps am I to take so as not to repeat the failure of the last few years?

My mind goes back to those far-away years when I once won first prizes. I shall always remember with pride that one year when I first showed at the Crystal Palace. I obtained two first prizes, and only showed in two classes. Once then I defeated my friend Mr. Baker and many other giants. How did I do it? and why have I not been able to keep up this form? I had not then many Roses; five hundred would be

are apparent, and the usefulness of the system will be admitted the very outside. I did not work half so hard then among by all practical cultivators.—Eds.] manure. I had no means of doing this, and I did not then understand that it was advisable to use it. How, then, was it I succeeded with fewer Roses and without liquid manure? The answer comes like a flash of lightning across my mind. "Virgin soil, and that of the very best kind." Yes, that must have been it. I took away the miserable stuff, half stones and balf sand, which composes my soil, and went into the lanes and got the turfy loam at the sides of the hedges, mixed this with decayed manure, and planted the Roses in this in good time, and left the rest to Nature; and although the competition was not quite so severe then as it is now, for Mr. Jowitt had not come to the front, and the Canon was then a mere beneficed clergyman whom I never had the honour of beating, yet it was sufficiently stiff for one handicapped like myself.

Next as to plants, and what stock did I buy? Well, I went to two of the great nurserymen who live on the Great Eastern line, and they supplied me with grand plants. Half were on the standard and half on the Manetti, and one did as well as the other. The seedling Briar was not then in existence, and I am free to own that when it did put in an appearance I was strongly advised (from perhaps an interested person) to have nothing to do with it. From that day to this I have never tried it except in the case of Marie Baumann, which is known to do well on it. But I mean soon to give it a thorough trial, and if it succeeds with me I shall once more put in an appear-

ance at the shows.

And now how can I combine Rose-growing with the herbaceous plants, bulbs, &c.? for it will of course be impossible for me to give up the latter. I know many people will say "If you try so many things you will fail in all." It may be so, but still I mean to try. My idea is this: To renew the soil in a certain number of beds, and to grow Roses planted therein at midd distance of the soil of the s wide distances. I would next plant bulbs between the Roses. In one bed 1 will have seedling Briar Roses and English Iris; in another Spanish Iris and Roses; next Gladioli mixed with dwarf Roses, and in another bed Daffodils; in the fifth bed Liliums, in the sixth Colchicums, in the seventh Amaryllises, and in the eighth Phlox; all these beds to contain dwarf Roses. I shall then have a succession of flowers as well as Roses, for bulbs according to my experience, so far from doing harm do good to Roses; for the liquid manure that is applied to Gladioli when in a growing state assists the Rose at the most important stage of its existence—viz., just before and while blooming. While speaking of liquid manure I must warn brother rosarians, or rather neophytes, against the undue or excessive use of this stimulant. Roses can stand a certain amount, but if the dose be over-strong instead of doing good the manure positively kills them. Manetti Roses are much more sensitive on this point than standards worked on the Briar. This is accounted for by the nature of the roots. The Briars has strong sucker-like roots which put forth rootlets that have the same relation to those of the Manetti as whipcord has to ordinary string. Anyone taking up a Manetti Rose must be struck with the very fine silk-like roots the Manetti sends up from the base; over-strong liquid manure entirely kills these

and the plant cannot grow.

Of all liquid manures night soil is the most dangerous. It is frightfully strong and burning, and can only be used with the greatest care. Being also the easiest and cheapest obtainable it is more frequently used than any other. No one has greater reason to know its dangerous qualities than myself, for I have killed I may say thousands of plants by the use of it. This year a friend of mine asked me to go and see his Roses; they were all young plants on the Manetti growing in virgin soil, and doing fairly well. He told me he had a tank full of liquid manure, mostly night soil, and asked my advice about using it. I advised him to put it on weak, and I myself superintended the mixture of it. We made it quite weak enough according to my judgment; but when I had left, the man, finding that as he began to empty the tank he found it looking weaker and ceased to mix it. He was misled by the clearer appearance of the water, and imagined it weaker, when all the time it was equally strong. What was the consequence? The Roses ceased for the time to grow, the foliage has fallen off, and my friend writes to me to ask if I can let him have any buds, as his Roess have made no wood and are apparently going back. My friend, Mr. Baker, uses liquid manure with the greatest success, but never night soil. His mixture is made from sheep manure, soot, and a little guano. He applies this all through the blooming season—i.e., before and during the shows, for as soon as

the last show is over he never stimulates his plants, but leaves them to grow as Nature dictates. But some great resarians have grown and shown splendid Roses without ever applying liquid manure. The late Rev. George Arkwright, whose Roses, particularly his Souvenir d'un Ami, will never be forgotten, used to say, "I never water; I live on the side of a hill, and have no means of watering, and I do not find my plants require it. In the driest seasons I only move the soil with a hoe so as to let the dew and moisture the easier down to the roots." is therefore possible to grow Roses to great perfection without the aid of liquid manure. I am of course now referring to cutback Roses, not to maidens, for very few of the nurserymen ever attempt to apply liquid manure to their plants. They grow far too many to be able to do this. Mr. Cant of Colchester does indeed use liquid manure, but only in limited quantity, and among these the famous Tea La Boule d'Or, which he alone appears to grow well, receives the most.

Another fallacy that appears to be exploded, at all events to have been abandoned as such by the amateur champion of the year, is the custom of buying new plants every year. Some few years ago the idea was that plants more than three years old were useless for exhibition. Now the great exhibitors believe that the older the plants the better they are. Mr. Baker is firmly convinced of this, and now only discards weak plants and replaces them with new ones.—WYILD SAVAGE.

CURRANTS AND GOOSEBERRIES.

IT appears to me that sufficient attention is not given in the gardening papers to small fruits, especially bush fruits, and as a consequence there are many inferior varieties cultivated to the exclusion of those which are of superior quality. I do not feel at all qualified to dictate on the subject, as I am not sure of some of the names of the best of those I grow, and will therefore merely send these remarks as a feeler, and ask for contributors to help to eradicate the worthless varieties, for good varieties will take no more room and their cultivation is not more difficult.

Probably to many of your readers a Black Currant is a Black Currant and nothing more, but there is as much difference in the quality of Black Currants as there is in that of different kinds of black Grapes, and nearly as much difference in their time of ripening. The cultivation of them is also quite as important, for they are, or should be, everybody's fruit. Birds are less troublesome to these than to most other fruits, and so long as a Black Current is not starved it is not particular about soil or situation. If you say, "Black Currants are sour," I reply, Did you ever taste Lee's Prolific well grown? This Currant is worthy of a place amongst the dessert of any nobleman's table. I do not, however, consider it the best for cooking purposes, but I may be wrong. It is a notorious fact that many of the best flavoured fruits lose a great portion of their good character when cooked, and I am inclined to think this excellent Currant does. Black Naples is the earliest and the most acid Black Currant I have; it is the one which we generally gather in quantity for preserving, and for which purpose it is exceedingly good, but it wants gathering as soon as it is ripe or the best of the fruit will fall. Next comes Lee's Prolific Black, and if you eat a berry of this and then go back to Black Naples you will find there is a considerable difference in Black Currants. Black Grape is also an excellent Currant, not so sweet as Lee's, but considerably less acid than Black Naples, and in my experience it is the latest to hang on the bushes. I am gathering very fair fruit from it now (September 4th). There is still, I believe, in extensive cultivation the old black variety which should be entirely got rid of.

Of Red Currants Raby Castle under many aliases is undoubtedly king. Its only fault is that it fruits too freely, and consequently grows too little: it wants liberal treatment. When trained to a wall it is an easy matter to thin the fruit, but it is not easy to do this on large bushes. It retains its foliage longer than any other Currant with me, and consequently its fruit remains plump till the end of November, and sometimes later. It is not so long in the bunch as the long-bunched Red, but it has a larger berry of brighter colour, and it certainly makes a very handsome-looking dish. I have just measured some berries seven-sixteenths of an inch in diameter, or more than 1½ inch round, and that too from large bushes with at least a peck of fruit on each. It is late in ripening. I have tried many varieties and more names for the early and general crop, but I do not think the Red Dutch is yet superseded, certainly not by La

White Dutch is the only white variety I know worth growing. Of Gooseberries the first to come in is Early Sulphur; it always crops well, and is less subject to the caterpillar than other varieties. Next is Green Gascoigne, and then what is here called Cockspur, a medium-sized rough red, one of the very best flavour. I have what appears to be the same sort from a local nursery under the name of Red Champagne, but I can hardly think it is the true Red Champagne, as it scarcely keeps well enough for that, which I have seen hanging very late in the north. Can anyone tell me if Red Champagne will keep well in the south? say as well as Warrington, which is by far the best for keeping, and it always bears very abundantly. I have one called Yellow Warrington which is useful as a variety at this time of year, but its keeping qualities are not excellent, nor is its flavour to be compared with the red variety. Moreover, it is not a Warrington at all, for its growth is erect and that of Warrington is drooping. The varieties I have named keep up a continuous supply in ordinary seasons from the middle of July to the end of September, and are in their respective seasons the best which I have. I should like to have other colours if I could secure quality at the same time, say a good first early red or a good late yellow or green, for the Gooseberry is an important crop. I have had Yellow Champagne, or at least one called by that name, and discarded it as of not sufficient merit. Who will help me to make my selection complete ?--WM. TAYLOR.

CULTIVATION OF ZONAL PELARGONIUMS.

WE know of no class of plants so easy of cultivation, while rewarding us at the same time with so much late bloom during the winter months, as these Pelargoniums. Cuttings that were struck in the spring and the plants grown on in pots for indoor decoration should now be cut back, and, if necessary, shifted into larger pots or be top-dressed. Place them in a position where they will get as much sun as possible to ripen their wood; they will soon break freely, and will again commence flowering. Plants that are not required for indoor decoflowering. Plants that are not required for indoor deco-ration during the summer should be potted and plunged in the ground in an exposed situation, and when the usual occuants of the conservatory during the summer months—viz., Fuchsias, Achimenes, Coleuses, &c.—are getting past their best the Geraniums can be taken up and introduced into the house as required. The advantages of planting them out in their pots are obvious. Firstly, they will not make such rank growth during the summer, and will show no signs of flagging in removal to their new quarters. The blooms should be picked off during the summer before they commence seeding, and a shift into No. 32 pots will last them during the winter. They should be kept as near the glass as possible; in fact, the lighter and drier the house is during the winter the better they will bloom. As regards the temperature required—if the plants are wanted merely for decoration 50° by day and 45° by night during December and January will be sufficient, but if a large supply of cut flowers is required 10° higher both by night and day will be advisable. The soil well suited for growing Pelargoniums is three parts of good loam, sharp sand and well-decayed manure to compose the remaining part. On choosing the varieties suitable for winter flowering select those that were exhibited by Mr. Cannell at the Royal Horticultural Society's meeting last winter; but no collection must be without the Scarlet and White Vesuvius, the latter being quite as free-flowering and quite as indispensable as the former.—WM. ETHERINGTON.

STRAWBERRY FORCING.

In discussing the merits of the two plans of raising Strawberries—viz., layering in 3-inch pots and afterwards potting on, and layering in their fruiting pots at once, Mr. Bardney lays great stress on the fact of his having tried both ways, and therefore settled the question, as he thinks. There are others, however, who have experimented in the same line, and the question has also been discussed before, and the general result of experiences and observation among Strawberry forcers seems to be that the system of layering in the fruiting pots possesses no advantages over any other, while it is cumbersome and inconvenient in various ways, for which reason the plan is seldom practised. If Mr. Bardney is anxious to find an authority who has tried and compared both systems like himself let him turn to page 232 of Thomson's "Fruit Culture Under Glass," where he will find that the author decides in favour of layering

in 3-inch pots first and potting off in the usual way. The present writer has seen Mr. Thomson's plants many times, and his crops as well, and better he never saw, and very seldom as good. Our plants are first layered in a ridge of good soil, where they root more quickly than in pots standing above the surface of the ground, and are lifted with one bunches of roots, and never even flag in potting. Layered in this way not a tenth of the labour in watering, &c., is incurred.—FORCER.

POTATOES.

I AM tempted by reading dismal accounts of Potato failure to give my small experience. I planted small whole sets from March 25th to April 15th, all my earliest being Myatt's Prolific. Following the advice of the Journal I made very wide rows, some by way of experiment 34 inches wide, and the result to me is very gratifying. I have a splendid crop; in some instances I have taken as many as thirty-six good sized tubers from one plant, and am glad to say there is no disease, while my neighbours are all bitterly complaining. 1 am convinced that the wide rows are a great cause of my success, as the haulms get plenty of air—an essential in such weather as this. About a fortnight ago I had all the haulms pulled out as a preventive. As a sample of the lateness of the season I may tell you that one of my neighbours, a farmer, was cutting his first crop of hay to-day, September 8th.—C. C., Cheshire.

ROSES AND THEIR CLASSES.

WITH the recent influx and probable multiplication of Mr. Bennett's lovely pedigree Roses, and the introduction of hybrids from the continental and home raisers, it is becoming a somewhat difficult matter to catalogue such under their proper class; and as the former may be largely shown next year, some perplexing questions may arise for the judges, which perhaps a timely hint may prevent, and allow the schedules for next season's shows to be amended. For instance, Bennett's lovely Duchess of Connaught (H.T.?) is so much like La France (H.P.?) in colour, that except for its foliage and perfume it would not readily be distinguished from it; and although from the receipt of the provided class these pedigraes Receipt the Tage. observation I should class these pedigree Roses among the Teas for convenience, it becomes a question whether a separate class could not be created for them and other Hybrid Teas-Madame Bernaix for example. Cheshunt Hybrid, again, is to my thinking out of place shown in a box with Teas, while Boule de Niege, Olga Marix, and its congeners are not quite at home with Noisettes (the latter has done us good service as a pure white), though not often shown; while Madame Noman and Mdlle. Bonnaire are scarcely Hybrid Perpetuals, though they come in well for colour in a front row. If La France is to be classed as a Hybrid Perpetual, where is the distinction to be drawn between it and the Duchess of Connaught as named above? Further, the Gloire de Dijon race, which now contains some distinct and fine varieties—Belle Lyonnaise, Bouquet d'Or, and Madame Berard, are not at home with the Teas; and I have heard rosarians object to their being pitted against such chaste blooms as Niphetos, Marie Van Houtte, Devoniensis, &c., while Gloire de Bordeaux, which if I recollect rightly, was once called a Bourbon, is now sometimes classed in Teas. This would with Cheshunt Hybrid come into a class with the Dijons, but then Baron Gonella is first cousin to it.

I throw out these hints and remarks with a view of starting the question. The matter might be taken up by the National Rose Society, and their dictum would soon cause it to assume a practical shape. While on this subject allow me to state that some reformation is required in the schedules of many societies as regards the larger classes for Roses. The competition does not always allow that "fair field and no favour" which all exhibitors look for. For instance: A, B, and C show forty-eight trebles; A sets up all Hybrid Perpetuals; B thirty Hybrid Perpetuals and eighteen Teas; and C shows the best and brightest Hybrid Perpetuals and few Teas. The judges with, perhaps, an excusable partiality for Tess, give B the first, C the second, and A the third prizes. A complains that by the unwritten law of rosarians he is rightly first and complains; C says his Roses are the best and he ought to have had the first place. As a preponderance of Teas his stands are deficient in size and colour as viewed occasionally, and Teas should not have placed B over him. Why does not the Rose Society make a rule that forty-eight trebles shall not contain more than twelve Teas, twenty-four trebles not more than eight, and so on; while singles might follow on the | fine bunches of Black Prince and four small but finely finished

same plan? I agree with those who think that Teas and Hybrid Perpetuals should compete in separate classes, but in the singles a few Teas are a great feature; the delicate colours of Adam, Madame Bavy, Alba Rosea, &c., and the rich golden yellow of Maréchal Niel can scarcely be overlooked.

If Mr. Bennett's Roses are to be classed as Teas there is little doubt they will be largely drawn on for contrast in boxes of twenty-four and upwards; in fact, the Tea class, always attractive at exhibitions, might increase its numbers, say to eighteen and thirty-six. Everyone admires Rose buds, and justly so; nothing can be more lovely than such. I have often wondered why prizes have not been offered for twelve or eighteen varieties, four buds of each. Possibly some of these matters may have previously come under the notice of the National Rose Society, but I have not a schedule by me. If they have received attention it should be made known to a wider circle.—Gronge BUNYARD, Nurseries, Maidstone.

EXHIBITION OF THE ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

THIS Exhibition, held at Edinburgh, September 10th, was the best this Society has held since the International of 1875. The best this Society has held since the international or 1848. The show of Grapes was especially remarkable, out-of-door fruit as a matter of course being next to a failure as a feature of the Exhibition. Vegetables were very largely shown, but were very deficient in quality to that generally staged in the northern capital. Cut flowers were also very deficient both as regards quality and quantity, whilst the show of pot plants was over the average both in numbers and quality. The Lawson Seed and quality and quantity, whilst the show or pot plants was over the average both in numbers and quality. The Lawson Seed and Nursery Company boldly eschewed the tables, and at the west end of the market filled a space of something like a quarter of an acre with fine groups of plants arranged on the floor. The centre bed of the group, oval in shape, was composed of a rich collection of hardy ornamental shrubs. This was flanked with round beds to match at each side, composed of stove and green-house foliage plants. The westmost group was made-up like the centre one of ornamental shrubs, was long and narrow, and arranged in an easy flowing line. The eastmost bed next to the ranged in an easy flowing line. The eastmost bed next to the body of the building was heart-shaped, and contained a rich collection of ornamental flowering and foliage plants. In continuation of this bed the other nurserymen connected with Edinburgh had large groups of plants staged on tables right down the centre of the hall, whilst a series of smaller tables on either side contained the competition produce, a broad table at the east end of the market backed with Firs finishing the furnishing of the hall in that direction. Altogether viewed from the gallery the hall in that direction. Altogether viewed from the gallery running all round the market the effect was very good, though we hope to see the Lawson Company's lead followed at any rate by the nurserymen at future shows. The nurserymen's tables were arranged with very much the same class of materials, Tree Ferns and Palms being profusely used for the centres, and furnishing plants filling up the remainder. In the table set-up by Messra. Ireland & Thomson the newer Crotons and Dracesnas, new Colemes, Pitcher Plants, and the newer foliage subjects were freely used, rendering theirs the most reckerche in the Show. In the Messes. Methew's, small plants of Lilium anratum were used in quantity with good effect to lighten up their group. Downie & Laird relied on boxes of cut florists' flowers, such as it is necessary to come to Edinburgh in order to realise their beauty. There were the best of the Phloxes, a splendid lot of Pentstemons, cut Roses, and some of their new strain of bedding Pansies. Phloxes in pots were also mixed amongst the foliage plants. In the Messrs. were also mixed amongst the foliage plants. In the Messas. Dickson & Co.'s stand we noted some boxes of cut flowers of double Chamomile well worth looking after. Mesers. Todd & Co. contented themselves with laying out a table for twenty-eight dinners, which though rather heavy in the arrangement attracted a deal of interest. Mr. Robertson Munro filled a large table with cut hardy herbaceous flowers, some 150 kinds being laid under contribution. Some stands of good Roses were exhibited by Mr. Hugh Dickson, Belfast, and Mr. T. Smith, Stranzer.

The fruit tables however, were the great centre of attractions.

The fruit tables, however, were the great centre of attraction, the Grapes especially being worthy of great praise. Something like three hundred bunches of these were shown, one exthing like three hundred bunches of these were shown, one exhibitor staging nearly fifty bunches on his own account. In the class for twelve bunches, six black and six white, Mr. McIndoe, Hutton Hall, Guisborough, Yorkshire, occupied the leading position with the following varieties:—Foster's Seedling, Golden Champion, two of Muscat of Alexandria, rather passe; Duke of Buocleuch, extra fine, and a small bunch of Bowood Muscat; Gros Guillaume, large, but hardly ripe; Gros Colman, the same; Madreefield Court, large and extra fine; Black Hamburgh and Alnwick Seedling, both extra fine; and a small bunch of Frankenthal completed the number. The second place was held by Mr. McIntyre, gardener to C. Tennant, Esq., M.P., The Glen, Peebleshire. The six white bunches in this collection were all Muscat of Alexandria, fine, but not up in colour. The blacks consisted of two fine bunches of Black Prince and four small but finely finished

Black Hamburghs. Mr. Hammond, gardener to Sir W. Lewson, M.P., Brayton, Carlisle, was the only other competitor, and to his collection the third prize was awarded. Three very fine bunches of Alicante were staged in this collection. In the class for eight bunches were five collections competing. Here Mr. J. Kirk, Ernspie, Castle Douglas, occupied the first place with an even and extra fine lot. Buckland Sweetwater and Alicante were particularly fine, the other varieties being Black Hamburgh and Duke of Buccleuch, two bunches of each. Mr. McIndoe second with Duke of Buccleuch, extra large Black Hamburghs, Foster's Seedling, and Madresfield Court, two of each. Third Mr. Louden, gardener to T. Daines, Eeq., The Quinta, Chirk, Yorkshire, Muscats were finely coloured, and Gros Colman extra fine in this collection but the collection but the collection of the collection but the collection of the collection collection, but as a whole the bunches were irregular in size. Seven exhibitors contested the class for four bunches, Mr. McIndoe being again successful here with an extra fine lot-Duke of Buccleuch and Muscat of Alexandria, grand; Black Hamburgh and Madresfield Court, extra fine. Mr. Kirk second, and Mr. Louden third. For two Muscat of Alexandria Mr. McConnachie, gardener third. For two Muscat of Alexandria Mr. McConnachie, gardener to Mr. Smollet, Cameron Honse, Alexandria, first with splendidly finished specimens, yellow as gold; Mr. McIndoe second, with bunches rather past their best. Two Black Hamburghs.—First Mr. J. Boyd, gardener to W. Forbes, Bsq., Callender Park, Falkirk, with extra fruit; second Mr. Curror, gardener to G. Douglas, Esq., Eskbank, with large double bunches. Two Golden Queens.—First Mr. McIndoe; second Mr. M. Ferguson, gardener to A. Usher, Esq., Oswald Road. An exceptionally bad class. The heaviest bunch of white Grapes was from Mr. Dickson, gardener to J. Jardine, Esq., Arkleton. with a handsome White Syrian, weighing 18 tbs. 8 ozs. white Grapes was from Mr. Dickson, gardener to J. Jardine, Esq., Arkleton, with a handsome White Syrian, weighing 18 lbs. 8 ozs. Mr. Kirk second with Trebbiano, 11 lbs. 2½ ozs. For heaviest black Mr. R. Cameron, gardener to J. Welsh, Rsq., Ericstane, Moffat, was first with a shabby bunch of Alicante, weighing 7 lbs. 1½ ozs.; Mr. J. Dickson second. For one bunch Muscat of Alexandria Mr. L. Carruthers, Stillwood, Corstorphine, was first with a small bunch, line in berry. For one Black Hamburgh Mr. J. Boyd was first with a fine specimen; Mr. W. Lees, Hillsbro' Castle, Co. Down, Ireland, was first for Alicante, compact and fine. For Lady Downe's Mr. J. Maule, gardener to Mrs. McMab, Howwood, Renfrew, was first with a small bunch, large in berry but not finished. Mr. McIndoe was first for Venn's Black Muscat; Mr. Gould, gardener to J. White, Esq., Dolphinton, for Gros Colman, wanting in colour; Mr. W. Kay, gardener to Sir J. Foulis, Bt., Milburn Tower, for Golden Champion, extra fine; Mr. G. Gordon, gardener to J. McIntosh, Bsq., Teviot Bank, for Duke of Buccleuch, poor; Mr. Boyd was first for Muscat Hamburgh, with a splendidly finished bunch. In the class for any white Grape not named in the schedule Mr. J. Dickson, Arkleton, was first with Golden Hamburgh, extra fine; Mr. Anderson, gardener to the Earl of Stair, Oxenford Castle, being second with a rice bunch of Mrs. Pearson. The finest flavoured white Grape was Duchess of Buccleuch, the corresponding black being Mrs. Hamburgh. The lavesthereth, the The finest flavoured white Grape was Duchess of Buccleuch, the corresponding black being Muscat Hamburgh. The largest-berried Grape was Gros Colman. The centre of the Grape table was raised, and furnished with table plants and bouquets.

raised, and furnished with table plants and bouquets.

Next in importance to the Grapes were the collections of fruit. For twelve sorts there were only two exhibitors, Mr. Johnston, gardener to the Earl of Strathmore, Glarmis Castle, Forfar, being first with a lot not quite up to his average. The Muscats, Alicantes, and Golden Queen Grapes were the finest in the Show, Black Hamburghs not so good, a Smooth Cayenne Pine Apple, Melons Victory of Bath and Lord Strathmore's Favourite, both fine, fine dishes of Peaches Red Magdalen and Gros Mignonne, Nectarines Pitmaston Orange and Duc du Telliers, and Brunswick Figs made up the collection. Mr. McIndoe was the other exhibitor, and was a very close second. Mr. McIndoe took first honours in the collection of eight sorts, showing eight bunches of Grapes, a Melon, Violette Hátive and Alexandra Noblesse Peaches, and Rigs. Mr. Fairgrieve, gardener to the Duchess of Athole, Dunkeld, second, and Mr. M'Connochie third. In the cellection of ten sorts of hardy truits Mr. Fairgrieve was first, Mr. McIntyre second, and Mr. McIndoe third. Pine Apples were limited in number; Melons a large competition. To Peaches the same remark applies, Mr. McKinnon, gardener to Viscount Melville, Melville Castle, taking first with a grand twelve, Mr. Hammond, Brayton, running a very close second. Other fruits do not call for particular mention. In the cut flower section the class for twelve Zonal Pelargoniums, three trusses of each variety, formed the most attractive display, other flowers being far below the average.

In the plant classes were some fine specimens; particularly so were the Fuchsias, which were large, well bloomed, and healthy. In the class for six flowering plants Mr. J. Paterson, Millbank, staged four healthy Heaths, well bloomed and large, a grand Statice, and a good Eucharis amazonica. The same exhibitor was also first for four Cape Heaths. Mr. Hammond, Brayton, was first with four foliage plants with Crotons majesticus and Weismanni, Thrinax elegans, and a Dasylirion; also for two Dracemas and two Crotons. For six Ferns Mr. A. Paul, Gilmore Place, was first with three grand Gleichenias, Microlepia hirta cristata, and a couple of Adiantums. For four Adiantums Mr. McDonald, gardener to D. McGibbon, Esq., was first with Flemingii, gracillimum, pedatum, and cuneatum, in grand order. Dr. Paterson, Bridge of well, I believe, on the London clay unless there was some chalk in the soil, and another authority said that Carolina superba only thrives well in the soil, and another authority said that Carolina superba only thrives well in the soil, and another authority said that Carolina superba only thrives well in the soil, and another authority said that Carolina superba only thrives well in the soil, and another authority said that Carolina superba only thrives well in the soil, and another authority said that Carolina superba only thrives well in the soil, and another authority said that Carolina superba only thrives well in the soil, and another authority said that Carolina superba only thrives well in the soil, and another authority said that Carolina superba only thrives well in the soil, and another authority said that Carolina superba only thrives well in the soil, and another authority said that Carolina superba only thrives well in the soil, and another authority said that Carolina superba only thrives well in the soil, and another authority said that Carolina superba only thrives well in the soil, and another authority said that Carolina superba only thrives well in the soil, and another authority said th

Allan, took the Orchid prizes. We had almost passed unnoticed a table furnished from the Botanic Gardens by Mr. Sadler. This group was very interesting. Numbers of carnivorous plants, such as Darlingtonias, Sarracenias, Nepenthes, Droseras, &c., medicinal and other useful plants, a grand panful of Disa grandiflora and various rare and uncommon plants were contained in it.

FAULTS IN GRAPE CULTURE.

What are the most common faults in Grape culture? Overcropping, excessive restriction of growth, deep narrow borders, bad drainage. What are the evils resulting from such a state of things? Poverty of colour, shanking, small bunches and small berries, sickly attenuated growth, and barrenness. These are all matters of moment to which the trying weather of the present summer emphatically draws attention. Never were badly coloured Grapes so frequently to be met with. Do not, however, let us lay all the blame upon the season, for undoubtedly the borders are often at fault. Very confidently do I assert that there never was a better season for Grapes having the advantage of well-drained shallow borders. It is mere repetition to write this, but apparently it will have to be written many more times before the full significance of the lesson is grasped and its teaching applied. Why is it that faulty Vine borders are so common? Ignorance of the process of bordermaking cannot be pleaded, it has been too frequently and thoroughly expounded for that. I fancy it must be that the first cost so often proves too heavy, and so the border is hurried over, the Vines are planted, and once established and fruiting tolerably well are left undisturbed, and the fault, though hidden for a time, is nevertheless there, and will inevitably makes its presence felt sooner or later.

I would suggest, whenever it is found impracticable to complete a full-sized border at first, to make it piecemeal year by year till the whole is accomplished. With care this method proves highly beneficial for the Vines, the roots quickly spreading into the annual supply of fresh soil, and sending up ample stores of sap to maintain that vigour of branch and foliage without which there never can be an abandant crop of well-finished fruit. The full value of shallow borders has long been known to our best Grape-growers. Many years ago when a very young man I went to see the Royal gardens at Windsor, and found in the vineries the finest crop of Grapes I had ever seen. Upon asking the depth of the very wide borders I was informed that they were of an uniform depth of 18 inches. Such a shallow border was then new to me, but I could not call it in question, for the sight of the huge clusters of fruit carried conviction with it.—EDWARD LOUKHURST.

THE GEOLOGY OF STRAWBERRY GROWING.

MR. C. P. PEACH has described his soil, which appears to words about mine. In the first place I live in a valley cut out of colitic rocks at some time or other by the river Churn, which is a tributary of Old Father Thames. In this valley the bare rocks and clay are not exposed but filled up more or less with gravel, and in this gravel various waterworn fossils are found, some of which are from the inferior colite and other formations miles away in the upper part of the valley. There are about 2 feet of soil on the top of the gravel, but part of this is made ground, the debris of houses, &c., during the Roman occupation of this place. The Romans were very fond of this valley, perhaps from the easy access to water, and in our garden there are the remains underground of part of at least six distinct buildings, and Roman coins, &c., are frequently turned up. In this soil the Strawberry flourishes well if properly manured. We already have grasses advertised to suit the various geological strata, and perhaps one of these days may have Strawberries the same. The late Mr. Rivers said his Eliza only flourished properly where there was some chalk in the soil, and another authority said that Carolina superba only thrives well in the sandy soils of the red sandstone formations, and the late Mr. Beaton said that no mortal man could grow the British Queen at Shrubland Park unless the whole nature of the soil was altered. This Strawberry, Mr. Darwin says, succeeds but in few places either in England or

admixture of sand or gravel. They succeed best on loamy soils, or where there is a deep loam on gravel; and in so many cases in this country the soils are not entirely derived from the rocks on which they rest, but composed of gravel, sand, and clay, the débris of other formations, that it would be difficult to construct a table of varieties suitable for each formation that would be practically useful, although I believe it would be right in the main, and the same difficulty has been experienced with regard to the Grapes. The soil also has experienced with regard to the Grapes. The soil also has something to do with the quality of the fruit. Some years ago when Trollope's Victoria was more generally grown the flavour was not considered good in some places, whilst here, and in some other soils, this fresh-eating Strawberry was attention of force with a red to the property of the property of the property and the property of the prop rather a favourite, and it is the same with some others, and our object should be to find out their peculiarities and grow those which thrive and do well in the district in which we live .- AMATEUR, Cirencester.

BRIGHTON HORTICULTURAL SOCIETY.

SEPTEMBER 10TH AND 11TH.

THE Autumn Exhibition of the above Society was held in the rooms and grounds of the Royal Pavilion, Brighton, proving a success in every respect. Plants were well represented; cut flowers were numerous, the Dahlias being especially good, but the flowers were numerous, the Danias being especially good, but the display of fruit was excellent, the entries numerous, and the general quality of the exhibits very fine both in size and finish. One large marquee contained the majority of the plants and cut flowers, the former being arranged on stages down the centre and the latter on side stages, while from the roof hung a number of large Chinese lanterns that were employed to illuminate the marquee on the first exemina of the Exhibition. In the remarkably hand, on the first evening of the Exhibition. In the remarkably handsome and spacious apartments of the Pavilion itself were arranged with excellent taste the Tree Ferns, foliage plants, and the extensive miscellaneous collections of plants from the various nursery-men in the neighbourhood. One fine group of new plants, such as Dracænas, Crotons, Orchids, &c., from Messrs. Veitch & Sons of Chelsea attracted considerable attention. The table decorations were in one room, while another contained the collections of fruit. There was only one disadvantage in exhibiting plants in these apartments, and that was their somewhat dark heavy appearance, but no doubt under artificial light the effect was excellent. The schedule enumerated a large number of classes in two divisions, one open to all England and the other confined to the gardeners and amateurs of Sussex. In most of the former the competition

was close and good.

PLANTS.—Stove and greenhouse plants were well shown; Mr. W. Balchin, nurseryman, Brighton, securing the chief award in the open class for eight varieties with a good Bougainvillea glabra over 6 feet high; a fair Allamanda Chelsoni; Dipladenia Brearleyana with handsome flowers; a neat pyramidal specimen of Rondeletia speciosa major, and several other plants. Mr. Meachen, gardener to C. Armstrong, Esq., Withdeane, followed, among his plants being a beautiful specimen of Erica cerinthoides. Mr. W. Huggett, gardener to Dr. Jeffery, Eastbourne, was placed third, the most noticeable plant in his collection being the elegant Swainsonia galegifolia albiflora, which is rarely seen in the exhibition tent. In the corresponding county class Mr. Meachen obtained the principal prize. These plants occupied nearly all one side of the stage in the marquee. On the opposite side were some remarkably handsome specimens of Coleus. Mr. W. Trangmar, gardener to Henry Davey, Esq., Mayor of Brighton, was most deservedly awarded the first prize for six enormous and richly coloured specimens of the following varieties—Sir Bartle Frere, Princess Louise, Queen Victoria, Nil Desperandum, Golden Gem, and a seedling. This was an exceptionally fine collection, the plants being 6 to 7 feet through. Mr. J. Shrives, gardener to the Corporation of Brighton, was placed second with good specimens, among which The Shaha and Victor Lemoine were especially noticeable for their vigour and colour. Mr. W. Balchin was third. The last-named exhibitor was adjudged the chief prize for six exotic Ferns: his specimens were large and good, including Cibotium regale, Cyathea dealbata, C. medullaris, and Gleichenia spelunce. Mr. W. Miles, nurseryman, Brighton, followed with much smaller specimens. The same exhibitors divided the prizes for foliage plants, both contributing good specimens. Fuchsias, Pelargoniums, Begonias, and Orchids were also shown, but not in such condition as to merit specification. was close and good.
PLANTS.—Stove and greenhouse plants were well shown; Mr.

condition as to merit specification.

CUT FLOWERS.—Over forty boxes of cut Roses were staged, and many of the blooms were good and bright for the time of year. In the open class for forty-eight triplets Messrs, Keynes and Co., Salisbury, obtained highest honours for a collection of rather small but bright blooms. The best were Maréchal Niel, Exposition de Brie, Madame Marie Rady, Marie Baumann, Ferdinand de Lesseps, Mons. E. Y. Teas, and Alfred Colomb. Messrs. Paul and Son, Cheshunt, were placed second with fair blooms; and Messrs. Mitchell & Sons, Uckfield, were third with indifferent specimens. For twenty-four triplets Messrs. Keynes & Co. and Mr. W. Balchin were awarded equal first prizes, but the blooms were not very good in either collection. Mr. J. Ridout, gardener to J. B. Hayward, Esq., secured the chief prize for twelve triplets with fair blooms, and he was followed by the Rev. R. C. Hales, Woodmancote. Dahlias were exhibited in superb condition, Messers, Keynes and Co.'s premier collection of forty-eight blooms being magnificent. The blooms were large, finely formed, and of the best varieties. The most noticeable were Perfection of Primrose, fine pale yellow; Christopher Ridley, rich glowing crimson; Sidney Herbert, bright purple lake; Criterion, an excellent pink; and Thomas Goodwin, very dark velvety red. Mr. W. Seale, nurseryman, Sevenoaks, was second, also sending good blooms, but not so regular as the preceding. Several fair collections were also staged in the county classes, notably by Mr. Allfrey, gardener to Miss Melvil, Henfield, classes, notably by Mr. Allfrey, gardener to Miss Melvil, Henfield, and by Mr. Edwards of Three Bridges. Messrs. Keynes & Co. were awarded first-class certificates for the following new and were awarded first-class certificates for the following new and excellent Dahlias—Lord Chelmsford, extremely dark purplish red; Mrs. Hodgson, yellow, the florets tinged with crimson purple; Ethel Britten, tinged with pale purple; Charlie Scott, scarlet, outer florets tipped with white, neat and pretty. Asters were shown, but of only medium quality. Mr. Cannell, nurseryman, Swanley, Kent, exhibited a large and choice collection of cut flowers not for competition, including Verbenas, French Marigolds, Pelargoniums, Hollyhocks, &c.; and Messrs. Wm. Paul of Waltham Cross and Messrs. J. Laing & Co., Forest Hill, contributed boxes of cut Roses in fair condition.

The table decorations were numerous and generally tasteful.

The table decorations were numerous and generally tasteful. The principal prizetakers were Mr. Seale, Sevenoaks; Mr. Burley, Brentwood; Mr. R. Miller, Shoreham; and Mr. Craggs, South

Norwood.

FRUIT.—As we have already observed fruit was abundant and in excellent condition, there being entries in nearly all the thirty-two classes provided. The chief interest, however, centred in the open class for six bunches of Black Hamburgh Grapes, where the first prize consisted of a cup, valued at ten guineas, presented by James Ashbury, Esq., M.P.; and here we may remark that there was great disproportion in the value of the prizes, for the second was only £2 and the third £1, and it was especially noticeable in this case as the competition was close. Mr. W. Coleman, gardener to Earl Somers, Eastnor Castle, Ledbury, was awarded the coveted cup for six superb bunches, fine berries, and handsomely finished; Mr. J. Williams, gardener to C. Liddell, Esq., Peasmarsh, was an excellent second, his collection being very close to Mr. Coleman's in point of merit, and indeed the Judges experienced some difficulty in arriving at a decision. Mr. J. Goldsmith, gardener to E. Hardwick, Esq., Tonbridge, was placed third with rather small bunches but of fair quality. There were ten competitors in this class. Mr. Coleman was again to the front with six fine bunches of Muscat of Alexandria, and was followed by Mr. Osborne, Kay's Nursery, Finchley, and Mr. W. Lacey, garclass for six bunches of Black Hamburgh Grapes, where the first six fine bunches of Muscat of Alexandria, and was followed by Mr. Osborne, Kay's Nursery, Finchley, and Mr. W. Lacey, gardener to C. S. Mortimer, Esq., Wigmore, in the order named, with fairly ripened fruit but small; seven entries. Mr. Coleman was also first with three bunches of Black Hamburghs; Mr. A. Bashford, gardener to Miss Douglas, Tunbridge Wells, and Mr. Wickham, gardener to Colonel Hannington, Hurst, being second and third respectively. For a collection of ten dishes of fruits Mr. Rutland, gardener to the Duke of Richmond and Gordon, Goodwood, secured highest honours with fine Walburton Admirable Peaches, well-ripened Kirke's Plum, good Morello Cherries, a small Melon, and rather poor Grapes. Mr. H. Apted, Broadwater, Worthing, was second, his collection including good Black Alicante Grapes and Brown Turkey Figs. Many other fruits were well represented both in the open and the county classes, especially Peaches, Nectarines, Plums, and kitchen Apples, which we cannot note in detail; but the principal prizes were obtained by Messis. Rutland, Ford, Holman, Wise, Hutson, and Wady.

The management of the Show was entrusted to Mr. Shrives, gardener to the Corporation of Brighton, who has charge of the

gardener to the Corporation of Brighton, who has charge of the well-kept Pavilion Grounds, assisted by the Secretary, Mr. Edward Carpenter, and considerable credit is due to both gentlemen for the taste and care displayed in the arrangements. Visitors were very numerous on the opening day, but on the second the weather proved unfavourable, and that somewhat diminished their numbers.

GRAPES WITHOUT FIRE HEAT.

THE only explanation I can give to "A. C. M." (page 207) with regard to the Grapes exhibited at the Glamorganshire Show on the 20th ult., and ripened without fire heat, is that there is no means of heating the vinery in question excepting by an old crooked flue. When the fire is lighted at the end of this, sometimes it draws towards the chimney, but just as frequently out at the furnace door; always managing, however, to consume a good quantity of coal-often so much, indeed, that it is entirely out of proportion to the heat which we get from the flue, and we never use the flue at all when we can possibly avoid it. During April last, when the Vines were starting into growth, the fire was sometimes lighted at night, but it was never

in for more than two days at a time; and altogether the firing might amount to about ten days this season, but from the beginning of May until this day no attempt has ever been made to heat the house artificially. As "A. C. M." thinks it important to know whether the Vines were started with fire heat or not, perhaps he will inform us how much importance he attaches to the amount of firing I have just stated, and if it proves that the Grapes were ripened with the aid of fire heat? Respecting the climate of Glamorganshire being salubrious, it may be more so at times than some other parts, but it would be difficult to find a person in the county who can remember it being so this season. The fact of the matter is, and it may interest "A. C. M." to know it, that those who have to grow Grapes, Pines, &c., in quarter-heated houses have just to do the best they can under the circumstances, and they soon find out that the hard-and-fast line laid down about temperatures and artificial heat is not so absolutely necessary to fair success as some imagine it.-J. MUIR, Margam.

THE HOLLYHOCK FUNGUS AND ITS PREVENTION.

AFTER having been baffled by the disease which at one time threatened the extermination of the Hollyhock, we tried a plan which has been not only completely successful, but at the same time the operation is so simple that all whose plants are infested with the fungus can soon destroy it with very little trouble by carrying out the following simple plan.

After the plants have done blooming (or earlier if desired) cut them down in the usual way, removing any shoots that have grown at the base of the plants, taking care not to disturb the dormant buds that will be found beneath the soil. Burn at once all the stems, leaves, and shoots that have been cut from the plants, and cover each plant with any light soil 3 inches in depth. Allow the plants to remain in the ground for about three or four weeks. By this time many will be pushing through the soil and quite free from fungus; they can then be taken up and potted, and are ready to be placed in heat when required to produce cuttings for propagation. We have about a hundred plants growing this season, clean and healthy. Many of the leaves measure from 12 to 15 inches in diameter, and yet the parent plants were greatly infested with fungus last autumn, but after passing through the above opera-tion we have not seen the slightest appearance of the fungus. We hope the day is not far distant when this pest will be banished from our land, and the Hollyhock again take its place as one of the finest and most majestic of our autumnal decorative plants.—JOSEPH OLIVER, Eslington Park.

ROYAL HORTICULTURAL SOCIETY. SEPTEMBER 16TH.

THIS was the last of the fortnightly meetings for the season and there will not be another until October 14th. Numerous collections of plants and cut flowers were exhibited, the Dahlias

sections of plants and cut flowers were exhibited, the Dahlias being especially fine, and Messrs. Veitch's group of plants attracted general attention owing to the large number of Nepenthes it contained. Messrs. Cannell, Keynes, and Walker were the principal exhibitors of cut flowers. Those from the first-named gentleman admirably illustrated the gradual floral advancement of the Dahlia. FRUIT COMMITTER—Henry Webb, Eq., in the chair. The duties of the Committee were very light on this occasion. Mr. C. Osman, South Metropolitan District Schools, Sutton, Surrey, sent a scarlet-fleshed Melon not of very good quality. Mr. Hyde, Farnborough Park, was accorded a letter of thanks for a seedling Melon of fair quality named Hyde's Hybrid. Mr. Killick sent a Melon of fair quality named Hyde's Hybrid. Mr. Killick sent a dish of a white transparent Apple, which was characterised by the Committee as very good and deserving of cultivation in every collection; also dishes of Suttons' Magnum Bonum Potato, which Mr. Killick states was the only variety out of forty grown in one field that was quite free from disease; and Suttons' Hed Fluke, of

which only 5 per cent. were diseased.

FLORAL COMMITTEE.—J. McIntosh, Esq., in the chair. tensive and imposing group of plants was exhibited by Messrs. Veitch & Sons of Chelsea. From a bar elevated about 6 feet above the table wave encounted. above the table were suspended numerous fine Nepenthes in baskets, and below them were arranged Orchids, Crotons, Rhodo-dendrons, &c., the central plant being a handsome specimen of Nepenthes Rafflesiana bearing nearly twenty large pitchers. The Orchids were good, and the most noticeable were the following:— Zygopetalum maxillare, with nine spikes of its distinct flowers; Saccolabium Blumei majus, three long spikes of fragrant delicate-hued flowers; Cattleya Harrisonii, very pretty, sepals and petals pale purple, labellum with a crimped margin slightly tinged with

the same colour; Odontoglossum grande, bearing seven large and handsome flowers; Leelia elegans, labellum extremely rich bright namesons in the principal Nepenthes that were represented were N. hybrids, N. Chelsoni, N. Wrigleyans, N. Ratcliffians, N. zealanica rubra, diminutive pitchers; N. Courti, N. Hookeri, N. intermedia, N. hybrida maculats, N. Sedeni, and N. Kennedyans rubra, all of which vary considerably in the form, size, colour, and markings of their pitchers. Among many other noteworthy plants the bright-coloured hybrid Rhododendrons Princess Fredericki and Duchess of Edinburgh were especially prominent, also the finely variegated Erythrina marmorata, and several Crotons. First-class certificates were awarded for Cypripedium cenanthum, a hybrid between C. insigne Maulei and C. Harrisonianum, the petals and labellum are dark-coloured, the upper sepal being streaked and ispetium are dark-coloured, the upper sepal being streaked and spotted with dark red, margin white; C. calanthum, small flower, sepals spotted near the base, upper sepal greenish, streaked with dark red; Nepenthes Rigleyana, a hybrid between N. Hookeri and N. phyllamphora, narrow greenish pitchers mottled with red. A special vote of thanks was awarded for the group.

special vote of thanks was awarded for the group.

Mr. William Bull, Chelses, sent several new plants, including Coleuses, Orchids, Palms, and a Drosera, D. dichotoma rubra, for which a second-class certificate was awarded. It differs from the species, as the name expresses, in the red colour of the glandular hairs that cover the leaves. Dendrobium Goldiei, an exceedingly pretty Orchid, bears a spike of small, bright, purplish-lake-coloured flowers, the sepals having a fine margin of white. Calyptronoma Swartzi is a handsome Palm with graceful bright green pinnate leaves. Messrs. J. Keynes & Co., Salisbury, exhibited a stand of three dozen Dahlia blooms in superb condition, and including several beautiful varieties. The best were Ethel Britten, florets white tipped and tinged with purple, excellent form, first-class certificate; Triumphant, bright purple lake, a handsome flower; William Ady, very distinct, pale purple streaked with maroon. Miss Browning, bright yellow, Mr. J. M. Gilkes, Wickham, Newbury, sent cut blooms of Quilled Asters, several of which were very good, but no names were attached. A silver Banksian medal was awarded.

Mr. H. Cannell, Swanley, Kent, contributed an extensive collection of Dahlia blooms representing the bedding, Pompon, Show, and Fancy types, also the single forms. The best of the bedding varieties were King of Dwarfs, very deep purple; Queen Victoris, good yellow; Rising Sun, bright scarlet; Crimson King, very dark crimson or maroon. Among the Show varieties the most dark crimson or maroon. Among the Show varieties the most noticeable were Rifleman, neat flower, bright crimson; Countess of Lonsdale, large, beautiful in form, pink; Victory, very dark maroon; E. Newcombe, pale yellow; H. Turner, white, with a faint tinge of purple in the lower florets. The Fancy varieties Queen Mab, R. Burns, and Summertide were the best. The best Pompons were Sunshine, scarlet; Snowflake; Hercules, bright pink; Triomphe, good yellow; Sappho, dark crimson; White Aster; Sensation, pale yellow; and Rigoletto, maroon. The single forms represented were Cervantesti, mexicana, coccinea, lutes, glabra, viridifora, the peculiar green-flowered form; Yuaiczii, the scarlet Cactus Dahlia, for which a botanical commendation was awarded; and Paragon, a remarkably pretty form, mendation was awarded; and Paragon, a remarkably pretty form, the outer florets large, dark marcon in colour, with a light margin. Mr. Cannell also sent a box of Cockscombs and Tigridia Pavonia var. grandifiors, all very good and showy. A cultural commenda-tion was awarded for the Tigridias, and a vote of thanks and a silver Banksian medal were awarded for the entire collection. Mr. B. Lloyd, Brookwood Asylum, Woking, exhibited some seedling Coleuses and a specimen of Ophiopogon Jaburan aureo-varieing Colenses and a specimen of Ophiopogon Jaburan aureo-varie-gatum, with narrow variegated foliage and scapes of pale purple flowers. Mr. J. Smith, Edmonton, and Messrs. Rawlings Bros., Romford, each sent collections of seedling Dahlias, some of which were very bright and neat. The former was awarded a vote of thanks. Mr. J. Y. Mould, The Nursery, Pewsey, Wilts, sent cut flowers of Verbenas. A first-class certificate was awarded for the

flowers of Verbenas. A first-class certificate was awarded for the variety Mr. Thompson, flowers large, scarlet with a white centre, and compact truss. Several other good varieties were shown, notably Mrs. Mould and Warren Hastings.

Mr. B. S. Williams, Upper Holloway, exhibited a group of plants, including Orchids, Palms, Ferns, and miscellaneous stove plants. A specimen of Tillandsia Lindeni, claiming to be the true species, was awarded a first-class certificate, but it was referred to Dr. Masters for identification. The bracts are pink, closely imbricate, and flattened out into an elliptical-shaped spike, bearing purplishblue flowers, affording an agreeable contrast. A similar honour was awarded to Nepenthes robusts, a hybrid between N. Hookeri and N. phyllamphora, very free in growth, and bearing numerous and N. phyllamphora, very free in growth, and bearing numerous pitchers marked with dark red. A vote of thanks was accorded. Mr. J. Walker, nurseryman, Thame, exhibited an extensive collection of Dahlias and Asters in fine condition as regards colour and form. The best Dahlias were Monarch, very dark marcon; Prince Asthur, good vellers, Fael of Pedner, purplish lake. Signarch. Arthur, good yellow; Earl of Radnor, purplish lake; Bismarck, crimson maroon. The best Quilled Asters were Purple Prince, Snowfiske, and Oxonian, purple with white centre. A silver Banksian was awarded. A vote of thanks was accorded to Mr. W. Clarke, gardener to J. Rains, Esq., Clapham Common, for Lilium auratum bearing a large number of flowers. Mr. H. Boller

of Kensal New Town sent several succulent plants. A secondclass certificate was awarded for Agave marmorata, dark green

leaves with whitish transverse bars.

Mr. C. Green, gardener to Sir G. Macleay, Bart., Pendell Court, mr. O. Green, gardener to Sir G. mackey, Barc, renden Court, exhibited flowers of Carolinea insignis, one of the Bombaces. The flowers are large, with narrow, whitish, recurved petals and numerous stamens with reddish filaments; it is extremely fragrant. A cultural commendation was awarded. Mr. Green also sent ruit spikes of Gunnera manicata, and flowers of Aristolochia Ksempferi and Nymphesa Eugénie. A vote of thanks was accorded for the group. A large collection of good seedling Tuberous Begonias was sent from the Society's garden at Chiswick. Many of the varieties were remarkably distinct and the flowers large. flowers large. A number of fine Asters were also contributed from Chiswick.

PORTRAITS OF NEW AND NOTABLE PLANTS.

DRACENA FLORIBUNDA. Nat. ord., Liliacese. — "This is one of the largest and most striking of all the known Dracenas. For many years the plant has been one of the most conspicuous members of the group of arborescent Liliacese in the Palm house at Kew, but it has never flowered until this present summer. Now that we know it completely, it proves to be a well-marked new species, remarkable for its very large drooping panicle and the great number of its crowded cylindrical racemes. It was received many years ago from the Botanic Garden at Mauritius, when Mr. Duncan was Curator there, without any precise information as to its native country. Mr. Horne, the present Director of the Mauritius Garden, thinks it very likely the plant was brought from Rodriguez, but it was not seen in that island by Professor Bayley Balfour. Its nearest ally is the West African Dracæna arborea of Link."— (Bot. Mag., t. 6447.)

Nat. ord., Labiate. - "Apparently a SALVIA ELEGANS. common and variable mountain plant of Mexico, as it is found amongst the collections of almost all the botanical travellers of that country, where it inhabits elevations of about 9000 feet. Seeing how vivid its colours are, it is singular that it should not earlier have been introduced into English gardens. The first person who appears to have cultivated it in this country is Mr. Wilson Saunders at his fine garden at Reigate, now dispersed, to the great regret of all horticulturists."—(Ibid., t. 6448.)

TRILLIUM NIVALE. Nat. ord., Trilliacere.-" One of the dwarfest of the genus, and is distinguished by its distinctly petioled leaves and white petals without purple stripes. It inhabits woods in the North-western States from Ohio westward to Wisconsin. It flowered in the herbaceous department at Kew this present summer."—(Ibid., t. 6449.)

RHODODENDRON LEPIGOTUM var. OBOYATUM. Nat. ord., Erices.—Native of Sikkim Himalaya. "In no way specifically distinguishable from Wallich's Nepalese plant, but it has larger more marcon-coloured flowers, and more copious glands on both surfaces of the leaf, this hardly differs from typical R. lepidotum. R. lepidotum is a native of the loftier interior ranges of the Nepal and Sikkim Himalaya, at elevations of 8000 to 16,000 feet. The specimen figured was raised from seed sent to the Royal Gardens from Sikkim by Mr. Gammie, which flowered in May of the present year. A stout or slender twiggy shrub, forming extended clumps, 1 to 4 feet high, branching from a woody tortuous rootstock."—(Ibid., t. 6450.)

ALLIUM KARATAVIENSE. Nat. ord., Liliaces.—"One of

the recent discoveries of the Russian explorers in Central Asia. It was first found several years ago by Sewerzow and Krause in the Karatau Mountains, east of Samarcand, and was gathered again in the summer of 1876 on the Alatau range by Dr. Albert Regel, who sent bulbs to his father at St. Petersburgh, from whom we received it. Of old familiar types in the genus it most resembles Allium nigrum, but it is much dwarfer, with large prominently veined leaves of firmer texture, and smaller flowers with very acuminate perianth-segments. It is quite hardy in England, and flowered in the herbaceous ground at Kew in the month of May of this present year."—(1bid., t. 6451.)

THE INTERNATIONAL POTATO EXHIBITION.

SEPTEMBER 17TH AND 18TH.

THE annual meeting of the Society whose object is the improvement of the Potato was held as usual in the Crystal Palace, and the quality of the exhibits was good considering the season. In the fourteen classes enumerated in the schedule, all of which were open except Class B, seventy exhibitors appeared, staging about 2000 dishes. The judging should have commenced at ten o'clock, but it was considerably past that hour before any awards were made, and all the classes had not been judged Potatoes. Messrs. Harrison & Sons of Leicester also exhibited a

until past one, before which time the public had been admitted,

until past one, before which time the public had been admitted, much to the inconvenience of the reporters.

In Class A, for twenty-four distinct varieties, Mr. Peter McKinlay, Headley Lodge, Penge, was first with Rector of Woodstock, Beckenham Beauty, Late Rose, Woodstock Kidney, Vicar of Laleham, Climax, Triumph, Snowflake, Beauty of Kent, Womerleighton Seedling, Manhattan, Breadfruit, Trophy, Early Rose, Schoolmaster, International Kidney, Seedling 18 B, Shelburne, Beauty of Hebron, Blanchard, Wiltshire Snowflake, Magnum Bonum, Grampian, and Barly King, all very good. Mr. Thomas Pickworth, Loughborough, Leicestershire, second; Mr. W. Kerr, Dargavel, Dumfries, was third; Messrs. Lott & Hart, Faversham, fourth; Mr. W. Ellington, West Bose Gardens, near Mildenhall, was fith; and Mr. J. Akchurst, Davington Priory, Faversham, was awarded an extra prize. Thirteen entries.

In Class B, for eighteen distinct varieties, Mr. F. Cresswell,

was awarded an extra prize. Thirteen entries.

In Class B, for eighteen distinct varieties, Mr. F. Cresswell, gardener, Stoke Park, Ipswich, was first with Covent Garden Perfection, Alpha, Brownell's Vermont Beauty, Woodstock Kidney, Blanchard, Porter's Excelsior, Snowflake, Cyster Kidney, Triumph, Brownell's Superior, Sutton's Magnum Bonum, Late Rose, International Kidney, Lady Webster, Norfolk Giant, Grampian, and Veitch's Improved Ashleaf. Mr. James Matthews was second, Mr. W. Finlay was third, Mr. W. Crump was fourth, and Mr. Wildsmith was fifth. Sixteen entries.

In Class C. for twelve distinct varieties. Mr. T. Pickworth

Mr. W. Finlay was third, Mr. W. Crump was fourth, and Mr. Wildsmith was fifth. Sixtsen entries.

In Class C, for twelve distinct varieties, Mr. T. Pickworth, Loughborough, Leicestershire, was first with Lady Gordon, Beauty of Hebron, Blanchard, Bresse's Peerless, King of Flukes, Triumph, Grampian, International, Early Vermont, Bresse's Probléc, and Premier; a fine collection. Mr. C. W. Howard, Bridge, Canterbury, was second; and Messers. Lott & Hart, nurserymen, Faversham, were third. Mr. Farquhar, gardener to Col. W. C. Gordon, Fyvie, N.B., fourth. Seventeen entries. One collection from Mr. James Clark, Cranemoor, Christchurch, arrived too late for competition. In Class D, for six varieties, Mr. T. Pickworth was first with Bressee's Prolific, Trophy, King of Flukes, Early Vermont, International, and Beauty of Hebron, very even and good; Messers. Lott & Hart were second; Mr. G. Martin, gardener to H. Day, Esq., Weybridge, was third; and Mr. James Matthews fourth. There were twenty-four entries. In Class E, for four dishess of distinct varieties, two round and two kidneys, Mr. F. Miller, Northdown, Margate, first with Snowflake, Ashtop Fluke, Radstock Beauty, and Blanchard, very good and even. Mr. James Matthews, gardener to E. Twopenny, Eq., Sittingbourne, was second; and Mr. Richard Dean, Hanelagh Road, Ealing, was third. Twenty entries. In Class F, for four distinct new varieties, Mr. Peter McKinlay, Headley Lodge, Penge, was first with Shelburne, Beckenham Beauty, Vicar of Laleham, and Woodstock Kidney; Mr. Richard Dean was second with Avalanche, Vicar of Laleham, Cosmopolitan, and Early Purple; Mr. R. Farquhar was third. Seven entries.

In Class G, for two varieties, one round and one kidney, Mr.

Mr. Richard Dean was second with Avalanche, Vicar of Laleham, Cosmopolitan, and Early Purple; Mr. R. Farquhar was third. Seven entries.

In Class G, for two varieties, one round and one kidney, Mr. J. Matthewa was first with International Kidney and Porter's Excelsior, extremely fine. Mr. C. W. Howard was second with International Kidney and Schoolmaster, also large. Mr. W. Charles, Fyvie, N.B., was third with the former variety and Grampian; and Mr. James Miller, Hamshall Park Gardens, Newbury, was fourth. Twenty-three entries. In Class H, for a dish of any white kidney variety, Mr. W. Kerr was first with Schoolmaster; Mr. Richard Dean second with Porter's Excelsior, and Mr. J. Pallister, Topcliff, Thirsk, third with Woodstock Round. Twenty-two entries. In Class I, for a single dish of any coloured round variety, Mr. R. Dean was first with Lye's Favourite; Mr. J. Miller second with Blanchard; and Mr. T. Pickworth third with the same variety. Sixteen entries. In Class K, for a single dish of any coloured kidney Potato, Mr. W. Finlay, gardener to Col. North, M.P., Banbury, was first with International, very fine. Mr. H. Harris, gardener to C. Eversfield, Esq., Horsham, was second with Woodstock Kidney, and Mr. P. McKinlay third with Beckenham Beauty. Twenty-nine entries. In Class L, for a dish of any coloured kidney Potato, Messrs. Lott & Hart were first with a good dish of Trophy; Mr. W. Kerr, Dargavel, Dumfries, N.B., was second with Red Kidney, and Mr. F. Oresswell was third with Brownell's Superior. There were seventeen entries. In Class M, for a dish of Radstock Beauty, Mr. F. Miller, gardener to J. Friend, Esq., Margate, was first with fine tubers; Mr. J. Hughes, Eydon Hall Gardens, Byfield, second, very close in quality, and Mr. F. Cresswell third with smaller tubers. Ten entries. In Class N, for the best dish of Suttons' Magnum Bonum, Mr. William Crump, gardener to His Grace the Duke of Marlborough, Blenheim, Woodstock, was first with fine tubers. Mr. W. S. Baldwin, New Brompton Kent, third; and Mr. C. W

large collection of Potatoes. Mesars. Vilmorin, Andrieux, & Cie., Paris, contributed a large stand of Gladiolus blooms; Mr. Boller a collection of Cacti, &c., and Mr. H. Cannell cut flowers of Dahlias, Verbenas, and Tigridias.

NOTES AND GLEANINGS.

Mr. IGGULDEN writes as follows on the FRUIT CHOPS IN ESSEX:-" It may be worth noting for the encouragement of the more northern readers of the Journal that Peaches, Nectarines Apples, and Plums are ripening well. Royal George and Bellegarde Peaches on the south wall are nearly ripe and of good size and colour. We gathered our first dish September Ilth from a west wall, the variety being the Grosse Mignonne. We shall have plenty of highly coloured Hunt's Tawny Necta-rines by the end of the week. Green Gage and Purple Gage Plums on the west wall are excellent, though in rather small numbers. Both the above varieties, and also the Orleans, Victoria, and Goliath, are ripening fast, but all are cracking badly in consequence of the wet weather. The Winesour is the only Plum that appears unlikely to come to perfection.

There is a good crop of them, and they are much prized for tarts, &c. Apples are ripening well, especially the Red Quarrenden, which are better than usual. Early Red and White Margaret have been over some time, but Doyenné d'Eté and the Jargonelle are the only Pears that have ripened as yet. Williams' Bon Chrétien are of good size, and will I think be fit for use in about ten days. Where flies and waspe are troublesome to the fruit crops nothing excels bottles containing a mixture of sugar, water, and beer. We to-day counted the contents of one bottle hung up only two days, and there were upwards of four hundred flies and wasps in it."

—— A CORRESPONDENT, "R. B.," writes as follows relative to the CROPS, &C., IN KING'S COUNTY, IRELAND:—"Crops of all kinds are very late, even Kidney Beans for the first crop are only forming their pods. Pears will be very small and probably ef inferior quality. Apples are more plentiful, although the excessive rain and almost sunless weather must have a very deteriorating effect on their quality. Plans are a tolerably fair crop, but since the late downpour of rain a large quantity of frait is dropping from the trees. From Saturday night it mined with very little intermission for thirty-six hours. Everywhere was flooded; a native declared in expressive language that it came down as "thick as himself." What will become of the farming peasantry I scarcely dare conjecture; the results must be very serious, as hay is scarcely all housed yet, and with the soft boggy land in a continual state of quagmire it will be no easy matter to save it in proper condition. Much corn is lying as flat as if the roller had been run over it. For fuel purposes peat is chiefly used; but then "turfs," as they are called, have been cut a considerable time, and sunshine is urgently needed to dry them, and altogether the prospect is a gleomy one both for gardeners and husbandmen."

— WITH a view of settling a disputed point as to whether CHMYSANTHEMUM TRIOMPHE DU NORD should be classed as a Japanese or a reflexed flower, the Kingston and Surbiton Chrysanthemum Society at a committee meeting recently held unanimously agreed that the variety in question should be allowed to be exhibited in all the classes for which prizes are offered in their schedule for Japanese collections, and not among the reflexed flowers, where it is usually to be found. That it is a pure reflexed flower no one disputed, but it was considered by the meeting to be as much a Japanese flower as Elaine, Peter the Great, and numbers of the other so-called apanese varieties. Triomphe du Nord is one of the oldest arieties—a very good grower, free bloomer, of large size, and a most telling colour in a large collection of cut blooms.

—— WE are informed that the ARBROATH COLLECTION OF ORCHIDS, collected by the late Mr. Miln, are to be sold at an early date.

— In the glass houses attached to the Finsbury Park we recently noticed a plant of the peculiar and rare MARTYNIA PROBOSCIDEA in flower. This is a North American annual related to the Sesamums and included in the natural order Pedaliacese. The flowers are large and curiously spotted, and emit an odour that may be considered agreeable by some persons, although the majority, perhaps, would not find it very pleasant. The leaves are large, cordate, and opposite, and the flowers are clustered near the summit of the stem. The strangest part of the plant is the fruit, which has when fully ripe two long curled horn-like processes. The fruit is rarely ripened

in England, but the plant mentioned is bearing some in a young state.

— MR. WILLIAM NICHOL, who has for upwards of twelve years been gardener to T. H. Powell, Esq., of Drinkstone Park near Bury St. Edmunds, has been appointed by Lady Gage as agent on her estate of Hengrave, also near Bury St. Edmunds. Mr. George Palmer, gardener to Col. Tremayne of Carclew, Perranarworthal, Cornwall, has been appointed as gardener to T. H. Powell, Esq., of Drinkstone Park. Mr. S. H. Brech has succeeded Mr. Marsh as gardener to the Marchioness of Bath, Muntham Court, Worthing. Mr. Thomas Carlton, Ashtead Park, Epsom, succeeds Mr. Don as gardener to Sir Charles Mills, Bart., The Wildernesse, Sevenoaks. Mr. W. Clarey, Wilderwich Park, succeeds Mr. McBean as gardener to W. R. Arbuthnot, Esq., Plawhatch, East Grinstead; and Mr. W. Goodall, late foreman at The Grange, Alresford, succeeds Mr. Beale as gardener to C. Hambro, Esq., Milton Abbey, Blandford.

— WE have received from Fisher, Clark, & Co., Boston, samples of their WATERPROOF TREE AND PLANT LABELS. They are very neat in appearance, and though made of specially prepared paper appear to be strong and durable. When written on with pencil and the writing is placed under a running tap the water has not the least effect on it. It is an inexpensive and useful label.

— MR. E. COOK, writing to us from Cornwall, states that the favourite mode of ERADICATING SLUGS in that county is by laying heaps of grains fresh from the brewers where the slugs abound, and three hours after dark spreading quicklime over the grains, which will be quite covered with slugs. By adopting that practice he has destroyed thousands in a night, and by repeating it half a dozen times during the summer his crops sustain no injury. It is, he observes, important that the grain must not lie on the ground for more than three hours after dark before the lime is applied, or the alugs will have finished their meal and departed. The same grains will not do for two nights, but must be used in a fresh state.

— MANY beautiful plants are now flowering in the HERBACHOUS GROUNDS at Kew that merit a place in every garden where this class of plants is specially grown. Echinacea angustifolia is a very attractive plant, as indeed are all the species of this genus; it grows 3 to 4 feet high, and bears numerous large conical heads, the outer florets of which are liguiste, reflexed, and bright rosy pink in colour, the central florets being darker in colour and tubular. It is a native of North America, and was introduced about twenty years ago. Linaria maroccana, a pretty annual from Marocca with linear leaves and dense racemes of bright purplish lake flowers, the lower lip being tinged with yellow. Chelone obliqua is, next to C. glabra, the oldest species of Chelone known in our gardens, having been introduced from North America about 1750. The lance-shaped leaves are opposite, seesile, and very dark green; while the large rosy flowers are borne in dense terminal spikes.

— WE regret to hear that Mr. DAVIS, for forty years gardener to Viscount Bridport at Cricket St. Thomas, Chard, Somersetshire, has met with a fatal accident by falling from a ladder when decorating the ball-room. Mr. Davis was highly esteemed by the family which he served so well, and by all who enjoyed his acquaintance.

FRENCH NOTES .-- No. 1.

EXHIBITION OF ROSES, &c., AT BRIE-COMTE-ROBERT.

EVERY Rose-grower has heard of Brie and its rosy surroundings, and they have known that it has Rose shows, for have they not grown Exposition de Brie for years? and as I had received a courteous invitation as Secretary of the National Rose Society to "assist" at its Show this year as one of the Jury, and had the time at my disposal, I consented to go, especially as I was very desirous of seeing my dear old friend M. Souchet of Fontainbleau, of whose increased infirmities and suffering I had heard very sad accounts, and so on Saturday week I was enabled to carry out my wishes. Brie is a small town of about three thousand inhabitants, and about twenty-three miles from Paris by the direct Vincennes route, but it was not thus that I reached it. I was at Fontainbleau, and was told by my friends there that if I went towards Paris as far as Comte-la-Ville I should find an omnibus that went from there to Brie, which was about four miles off; so on Saturday morning I left Fontainbleau, believing (although I had some slight misgivings on the subject) that I should reach Brie by one o'clock. When I arrived at Comte-la-Ville there was not a ghost of an omnibus to be seen. Was there no way? Oh, yes; there

was a volture a volonté, but, alse! it had started off early in the morning to Brie, and would not be back for some time. What was to be done? The innkeeper was away with the fly, but his wife rose to the occasion. Would monsieur object to a charrette? She would drive their cart horse. We should meet the fly, and then could get into it. I was glad to accept the offer, although the charrette, which was simply a market cart, was all but springless, and the seat was covered with American cloth, from which one continually slipped, and so, accompanied by a female friend of madame's, who evidently came for the fun of the thing, I in a most undignified manner started for Brie. My companions were merry enough, and what between the joiting, laughing, and talking, one's sides ached, so that about halfway I was glad to see the innkeeper returning. We got into the fly (a sort of sociable), madame taking the reins, and poor Mouton (why do the French so often call their horses this?) had to retrace his steps to Brie, where we arrived at a little before two, and thus far too early for the Exhibition. I was glad to recognise Mr. William Paul and

Mr. Arthur Turner, who were to act with me, and three French Judges, MM. Lacharme and Guillot, file, who is now a grey-headed old man and M Vignerous

old man, and M. Vigneron.

The Exhibition displayed the usual excellencies and defects of a French show. The tent was in the shape of a T, with a long corridor at the upper end of the cross of the T, in which were arranged the collections of fruit and vegetables; some fine groups of plants contributed by M. Bergman, gardener to Baron Rothschild at Ferrières, occupying the central position, to which they were fully entitled. At the further end of the tent was a rockery, from which issued the inevitable waterfall and rivulet running through the centre of the tent, and very prettily arranged. The Roses were in beds, the blooms being sunk in bottles and then the surface covered with moss, giving it a very pleasing appearance. Nor was all idea of beauty confined to the inside of the tent. The ground on which it stood was part of a common only six weeks ago; it was then handed over to the Committee, the space enclosed, and round the tent a garden was formed with

Fig. 26.—RAISING VINES AT COMBE ABBEY (See page 223).

its beds of Geraniums, Phloxes, &c., and its shrubberies of trees; grass seed was sown, and a pleasant spot was the result of the labours of the Committee of the Horticultural Society of Melun and Fontainbleau, under whose auspices the Exhibition was held.

and Fontainbleau, under whose auspices the Exhibition was held. The grand prize was worthily awarded to M. Bergman for six collections, consisting of some fine Dracenas, Crotons, and varie-gated plants; a fine central group, consisting of Palms, Orchids, Nepenthes, Anthuriums, Tillandeias, Begonias, a small group of Azaleas Comtesse de Flandres, Ceres, Princese Charlotte, and Madame Dominique Vervaene nicely in flower (but how was it done at this time of the year?) and for some very fine Grapes, consisting of Frankenthal, Chasselas de Fontainbleau, Chasselas Rose, Black Prince, Alicante, Gromier du Cantal, Foster's Seedling, Muscat of Alexandria, &c.

Muscat of Alexandria, &c.

The corresponding prize for nurserymen was given to M. Scipio Cochet for groups of stove and greenhouse plants, Bromelias, Ferns, Roses, Begonias, and Conifers. M. Leroy received a medal for a fine collection of about 300 varieties of Pears and 200 of Roses —most wonderful considering the season, which has been as unpropitious in France as it has been with us. There were some cut blooms of Dahlias in boxes, one stand having the number of the flower neatly pinned on a small piece of paper on the eye of the bloom! Asters, Gladioli, and certainly the most splendid lot of double Zinnias I have ever seen, and I have seen a good many both in France and England. I have seen them as double, but never so large; some of them were as large as a medium-sized Dahlia, and fully up in the centre. These were exhibited by M. Pernet, nurseryman of La Varence.

And now as to the Roses. Had I not known France and France exhibitions I should have been most grievously disappointed; but I was fully aware that Roses were never exhibited in France is anything like good form as we consider it, and that it was not to be expected in the month of September of such a season as this. It will be sufficient for me to say that I do not think there was in the Show a Bose we should have given third place to in any close competition. The prizes evidently aimed at quantity rather than quality, as they were offered for two hundred, one hundred, fifty, and twenty-five varieties. Quantity there was, but many of the Roses were unterly undistinguishable, and might also have borne any name the grower chose to affix to them. It settled completely to my mind the question as to whether we cannot substitute some more artistic plan and better arrangement than our own. Where there is competition I emphatically say, No I If you want to make a pretty sight you may do it with Roses as shown to-day, but the most lamentable confusion was the result. Let me take one instance: one bed contained the entries of one exhibitor for three different prizes, and two of these were arranged in circles round the bed, so that you had to find out how many rows went to one and how many to another. "Order dd not reign" at Brie, and had it not been for the efforts of the worthy son of a worthy sire, our good friend Rruset Bergman, it would have been impossible to have got through the judging at all After we had decided as to the winners of the prizes, we had then decided as to their value, whether they were to have gold, silver gilt, or allver medals, and the sort of medal, of which there were three or four different sizes of each kind. I cannot say that my

experience is "they manage these things better in France." What a waste, too, of time! The whole Show was not so large as many of our provincial ones, yet the whole of Saturday was given up to the preliminary work of judging, &c. It was not open to the public until the following day, and was to remain open on Monday. In what sort of condition could the Roses be in that hot tent by that time? Were there no seedlings oxhibited? Yes, M. Lacharme showed a light-coloured Rose of the Capitaine Christy style, but lighter in colour, I believe a cross between Victor Verdier and Sombreuil. It was, however, shown in but poor condition, and we could only indge honefully of it especially as its owner (a good could only judge hopefully of it, especially as its owner (a good judge) spoke very highly of it. There was also a red Rose shown by somebody else, which seemed promising, but it was of a shade of colour of which we have a large number, and so the Judges, as it was not in very good condition, made no award concerning it. I wish that I could have given some more satisfactory information to the readers of the Journal, but one cannot alter facts. One great cause of the difference between the shows of the two countries is the almost entire absence of amateur exhibitors. Amongst Roses there was not one, and until this alters it is absurd to compare the shows of the two countries.

absurd to compare the shows of the two countries.

But if there were failure in any way in the Show—and taking it from the Mench point of view there was anything but that, in fact most creditable to so small a place—there was none whatever in the banquet which followed, which was held at the Hôtel de Grâce de Dieu (what a name for an hotel!), and to which upwards of seventy sat down, presided over by M. Bose Charmeux, the President of the Society. The dinner was of the most recherched character, and I could not but think of what a contrast it was to one that one would be set down to in a small country town in England, while the vivacity and the talking were councily in contrast with one that one would be set down to in a small country town in England, while the vivacity and the talking were equally in contrast with the sober solemn way in what a company of the same number and character would go through their dinner with us. Well, we have high authority for saying the Rthiopian cannot change his akin; we cannot change the nature and characteristics of race, and hence we must learn to respect each other in our separate lines; even if we do take our pleasures sadly, still they are pleasures to us.

The Resistant is happy in having appear its more provincent mem-

The Society is happy in having among its more prominent members such men as MM. Camille Bernardin and Eugène Delamane.

More indefatigable and untiring men I never saw. Need I say that their courtesy was on a par with their energy, and that the English visitors had every reason to feel gratified with their re-ception? The banquet was not over when we were obliged to

English visitors had every reason to feel gratured with all a very specifion? The banquet was not over when we were obliged to leave. We got into a vehicle that was intended to hold three, but in which five managed to get; we had a jibbing horse, the cart came down on the springs with some ominous growls, and we were glad to be deposited at the railway station.

During the dinner M. Camille Bernardin announced to me that the "Journal des Roses" wished to present a medal similar to the one offered at Bris, a very handsome one, to the National Rose Society, to be competed for at our Exhibition at the Crystal Palace mark year, I believe for the same class—twenty-four Roses, three of each variety, one expanded, one half blown, and the other in had.

A pleasanter day, taking it all in all, I have not spent for some time, and shall have cause gratefully to remember Brie and its Exposition.—D., Deal.

NOTES ON STRAWBERRIES.

In reply to Mr. Thomas Forman on page 214, where he begins by suggesting that those who give their Strawberry experience should state soil, climate, &c., I might suggest it would have been as well if he had carried out his own suggestions, especially as he has written in a more than usually critical tone.

I never give notes about Strawberries that I have tried only a year. I have had Coxcomb for twelve or thirteen years, and Rivers' Eliza four seasons. Under certain conditions Coxcomb might be a medium season variety, but I have invariably found it later than Sir Joseph Paxton, Lucas, President, or in fact than three-fourths of about fifty varieties of Strawberries I have tried. My present collection with recent additions, after cutting out inferior sorts and duplicates, numbers thirty-one varieties. I planted Coxcomb in rows between Gooseberry bushes and Currants closely pruned, and I rathered some Strawberries only two days ago. Rivers' rows between thoseberry bushes and Currants closely pruned, and I gathered some Strawberries only two days ago. Rivers' Eliza is the better Strawberry and latest 1 know for a fine crop, very large, very prolific; with me the crop from only last year's plants is extraordinary. Traveller and Newton's Seedling are the other decidedly late Strawberries, all of which this late year I gathered in September. I have no doubt that by picking off early blossoms, or all June blossoms off some sorts, it would be quite possible to have fruit in the end of September and October; but onery. May we not have too much even of a good thing. but query, May we not have too much even of a good thing, just as I see many gardens spoilt by the anxious desire to have a bunch of Grapes in all months, in season and out of season? -C. P. PEACH.

CAMPANULA ISOPHYLLA.

I send you a spray of what I consider one of the most charming basket plants in cultivation. It is grown in cottage windows in this district, and is admired by everybody. It has been named as above by the authorities of Kew, but I am

Fig. 27.—Campannia isophylla.

doubtful if it is the true species, but only a variety of C. isophylla. In growth it is pendant, and the sprays become a mass of beautiful porcelain blue flowers, which continue in beauty for a considerable time. If you engrave the spray, I am sanguine that you will place before your readers one of the most charming plants that can be grown either for brackets, the margins of stages, window boxes, or various other decorative purposes. It is of the easiest possible culture, and is nearly or quite hardy.—J. B. B., North Riding.

THE LONDON PARKS. BATTERSEA PARK.

THE picturesque park on the banks of the Thames opposite Chelsea is widely noted for the tasteful manner in which subtropical and carpet bedding are carried out, and even in this adverse season there is much to admire. The great clumps of Cannas are not quits so imposing as usual owing to the

diminished growth of the plants, and the same may be said of the other exotics employed in the subtropical garden, such as Tree Ferns, Palms, and Musas, but the tall-growing species of Polygonum, particularly P. Sieboldii, are especially vigorous and striking. Funkias have also succeeded well here this season, as, indeed, they have in most localities, abundant moisture being evidently their chief requirement. Both F. subcordata and F. Sieboldiana are grown, and the freedom with which they flower and the fine foliage (particularly of the latter species, render them extremely serviceable for edging large beds of Cannas or similar plants. A bed of the graceful Bonaparteas with a central Dasylirion, in a carpet of Sedum glaucum, S. acre elegans, and Alternanthera amoena is pretty, the bright colour of the latter pleasantly relieving the softer hues of the Sedums. In another portion of the subtropical garden is a charming hed of Eucheine and Kalesonthes interspecied is a charming bed of Fuchsias and Kalosanthes, interspersed with the brilliant showy Tigridia Pavonia, and near to it is a clump of the distinct Polymnia grandis, surrounded by Veronica Andersonii variegata, Pelargonium Robert Burns, and Sempervivum tabulæforme, the spaces between the plants being occupied by Heliotropes. An elliptical bed of Grevillea robusta is also noticeable. Beneath the Grevilleas is the pretty foliage of the variegated Vine, and around them are bands of Lonicera reticulata aurea, Alternanthera magnifica, and Stellaria graminea aurea.

Of the carpet beds those on the east side of the subtropical garden, near the lake, are deserving of notice. Three beds there are always attractive—a small circle between two long beds. The two long beds are similar in design. In the centre are small ellipses of Alternanthera paroxychoides, margined with Kleinia repens in a ground of Mentha Pulegium gibraltarica, and surrounded by bands of Alternanthera amena, Sedum glaucum, and an edge of Echeverias. The circle is rather dull in appearance, for the Geranium molle aureum that occupies the centre intermixed with Lobelias has not coloured well; the edging consists of Herniaria glabra and Leucophyton Brownii. A short distance from the Tigridias already mentioned is a circular bed with a pretty design in Alternanthera amoena on a ground of Mesembryanthemum cordifolium variegatum, Leucophyton Brownii, and Pyrethrum Parthenifolium aureum, edged with Sedum glancum and Echeverias, a plant of Sempervivum canariense occupying the centre; and near by is another circle with a centre of Alternanthera versicolor, surrounded by bands of Mesembryanthemum Boltii, Leucophyton, Alternanthers amona, A. paronychoides, the golden Stellaria, Sedum glaucum, and Echeveria—a most pleasing and artistic covered with Antennarias are tasteful; a chain of Pyrethrum extends down the centre of each, and the small circles thus formed are planted alternately with Alternanthera amoena and A. versicolor, then follows a broad band of Mentha and an edge of Feverfew, the elegant Stonecrop, Alternanthera amœna, and Echeverias. In addition to those we have noticed the visitor will find several pretty designs round the refreshment rooms near the river, and the "coffin beds" on the road to the Albert Bridge entrance are worthy of attention, and equally so are the grand lines of Anemone japonica alba; the Yuccas (flaccida), too, near the rockery are very beautiful. The general appearance of the park is excellent, and reflects great credit upon Mr. Rogers and his able assistants.

KENNINGTON PARK.

Although this park is of small extent the bedding merits some attention, owing to its neat and bright appearance and the simplicity of the designs. The principal beds occupy that portion of the park near the Kennington Road, and are in two large oblong turfed divisions, one on each side of the lodge, and another extends down the centre of the park at right angles with the above. The central space in each division is sunk below the level of the paths, and the large beds there situated are planted with subtropical and flowering plants; on the higher portion are small circles and long beds of flower-ing plants, and at each angle is a carpet bed. Each opposite pair of the latter are similar in design, and all are pretty. One has a ground of Stellaria graminea aurea, a central circle of Alternanthera versicolor surrounded by fine lines of Feverfew and Herniaria glabra; two smaller circles of Alternanthera amorna on each side of this, and an edge of the same Alternan-thera and Sedum glaucum. Another bed has, in place of the Stellaria, Mesembryanthemum cordifolium variegatum, small circles of Alternanthera amœna, and bands of Mentha, Feverfew, and Alternanthera versicolor, margined with Sedum glaucum and

Echeverias. The beds of flowering plants are mostly edged with Pelargonium Daybreak, Viola Blue Bell, and Stellaria graminea aurea; the centres being occupied with Pelargoniums. One long ribbon border near the road is very attractive. At the back is a line of Polygonum orientale, in front of that Anemone japonica and hortensis flowering most profusely; next rows of Pelargonium Edward Sutton and Mrs. Holden, and a mixed edge of Lobelias and double Pyrethrums. This park is under the direction of Mr. Rogers, but the management is entrusted to Mr. Brown, who maintains it in excellent condition.-L. C.

HARPENDEN HORTICULTURAL SOCIETY.

THE first Exhibition of this newly established Society was held on Thursday, September 11th, in Rothamstead Park, Harpenden, and within the shadow of the famous laboratory of Messa. Lawes & Gilbert, whose patient and long-continued researches in the cause of agriculture have conferred immense benefits, not only on all cultivators of the soil, but on the whole civilised only on all cultivators of the soil, but on the whole civilised world; and it is somewhat surprising that long ere this the pursuit of practical horticulture, so closely allied with the botamical work of the Rothamstead Institution, should not have received public recognition in the locality. However, the matter has at length been taken up by several able and spirited horticulturists of the neighbourhood, and a Society formed under the Presidency of Mr. Lawes, the Committee having also the valuable services of Lieut.-Col. Durnford as Chairman, and the success achieved on Thursday angurs well for the permanency of the rathering.

Lieut.-Col. Durnford as Chairman, and the success achieved on Thursday augurs well for the permanency of the gathering. The principal marquees were tastefully decorated, and the twe ensemble of the largest, which was devoted chiefly to plants, was very effective. The plants, although not large nor extensively shown, contained a very good collection from C. R. Fenwick, Eq., High Firs, Harpenden (gardener, Mr. Underwood), who was first. Mr. Fenwick was also first for six foliage plants with well grown and healthy specimens of Bonapartes gracilis, Yucca curvitolia variegata, Croton pictum, C. Nelsoni, and Latania borbonica. The best six Ferns also came from Mr. Fenwick, who had hadsome and well-coloured plants of Adiantum trapeziforms. A. con-The best six Ferns also came from Mr. Fellwick, who have some and well-coloured plants of Adiantum trapeziforme, A. concinnum latum, A. cuneatum, Asplenium Nidus, Gymnogramma chrysophylla, and Pteris cretica albo-lineata. For six Tuberous Begonias Mrs. Warde, Harpenden (gardener, Mr. J. Elmer), was first, having fine plants of the best varieties. In Fuchsias a fine Begonias Mrs. Warde, Harpenden (gardener, Mr. J. Elmer), was first, having fine plants of the best varieties. In Fuchsias a fine bushy plant of Avslanche, with enormous double purple flowers, in the first-prize lot from Mrs. Warde was very attractive. An excellent collection of Caladiums, not for competition, came from Mr. W. Valentines of Bramingham, Luton. Colcuses were well shown and in high colour, and amongst the inter alia was a remarkable Orange tree about 2½ feet high from H. T. Hodgaes, Eeq., Harpenden, literally laden with clusters of large rips fruit, said to be the Myrtle-leaved variety, but the specific name of which I could not ascertain. A peck measure would hardly contain the fruit, which were all rips. Mr. J. Watson of St. Albans showed some good seedling Begonias of his own raing, in all shades from pure white to deep crimson. Six Cockscombs in all shades from pure white to deep crimson. Six Cockscombs from Mr. Toulmin showed good cultural skill.

rom Mr. Touimin showed good cultural Mill.

Cut Roses were staged, but not for competition, by Messra.

William Paul & Son of Waltham Cross and Mr. E. P. Francis of Hertford, and both being "at home" the blooms were fresh and the colours good. Messra. Paul had Alfred Colomb, Star of Waltham, Le Havre, Gabriel Tournier, Charles Lefebyre, Louis Van Houtte, Baronne de Rothschild, Niphetos, Souvenir d'Elise, Royal Standard Cetharine Marmat Souvenir d'un Ami Meddame Victor Standard, Catherine Mermet, Souvenir d'un Ami, Madame Victor Standard, Catherine Mermet, Souvenir d'un Ami, Madame Vicole Verdier, Duc de Montpensier, and Marie Baumann in good form, also a small, well-shaped, clear white bloom of Mabel Monison. There is, however, less in this Rose than its reputed derivative the Baroness, and it is not up to the show standard although a good garden Rose. It is wonderfully suggestive of my own Princess Louise, which was raised by crossing Madame Vidot by Virginal. Messrs. Paul also showed Duchess of Bedford in very fine autumn condition and it is satisfactory to find so good a Rose fine antumn condition, and it is satisfactory to find so good a Rose also a free autumnal bloomer. Mr. Francis had clean and highalso a free autumnal bloomer. Mr. Francis had clean and highcoloured blooms of John Hopper, Anna de Diesbach, Paul Neyron
(almost invariably fine and in show condition in the autumn),
Duke of Edinburgh, Louis Van Houtte, Dr. Andry, and Mälle.
Marie Verdier. For twelve Roses, single blooms, Mr. W. Valestines, Bramingham, was first, and for the twenty-four blooms
A. Flower, Esq., The Hyde, Luton, was to the front, his stand
containing good blooms of Marsechal Niel and Baron Hausmann.
Dahlias were for the season respectably shown by Mr. J. Henshaw of Harpenden, who was first both for twelve and six blooms.
Mr. Henshaw had also an extra stand of Pompon, Liliputian, and
other sorts, which included Cannell's single Paragon, very
striking, especially placed in contrast to the "bunchy" Mona.
Chauvière. For twelve Victoria Asters and twelve Quilled ditto
Mr. Flower was first, and for the former Mr. Henshaw second.

Mr. Flower was first, and for the former Mr. Henshaw second.
For six Victoria Asters Mr. Henshaw was first. The class for dinner table decorations was well contested, the regulations requiring tables 5 feet by 8 feet 9 inches completely laid for six

persons so arranged as to show the best means of utilizing fruit and flowers in their adornment. In most of the exhibits scarlet and nowers in their adornment. In most of the exhibits scarlet and masses of bright colour were dominant and the tables were producely loaded, but in the display made by Miss Henshaw lightness and the lighter tones prevailed. Miss Martha Elmes of Colewood, Harpenden, was placed first, Mrs. J. Mardale of Harpenden second, and Miss Henshaw third. In out flowers some fine Zonal Pelargoniums were shown by Mr. Fenwick; Masterpiece, Kleon, and Vivid being very fine, the individual blooms of the former exceeding 2 inches in diameter.

Fruit was not largely appears but the collection from Mr. C.

Fruit was not largely shown, but the collection from Mr. C. Pollard, gardener to H. J. Toulmin, Eq., Childwick Park, was very creditable. Mr. Pollard showed Black Hamburgh Grapes, St. Michael Oranges (of refreshing odour and colour), Pine Apple Nectarines. Green Gage Plums, and Morello Cherries. The Black Necturines, Green Gage Plums, and Morello Cherries. The Black Hamburgh Grapes from James Lyde, Esq., Ayott, St. Lawrence (gardener, Mr. Chuter), and the single bunch of Golden Queen from Mr. Fenwick were excellent. For a Melon Mr. J. Oakley, Lawrence End, Luton, was first with a large and prime Little Heath, and Mr. Valentines second with Scarlet Gen.

getables were good, and especially in the cottagers' depart-the tent allotted to the latter being well furnished; resert, the tent allotted to the latter being well furnished; Veitch's Autumn Giant Cauliflower being notably prominent and first-rate, but upon the whole the vegetables of Herts were not equal to those from the adjoining county of Bedford. For the collection in the gardeners' class Mr. C. Sibley, gardener to H. T. Hodgson, Esq., Harpenden, was first. For a brace of Cucumbers masset of the competitors staged Telegraph in fine condition, and in several instances 20 inches long, the first prize being awarded to Mr. Valentine, and the second to Mr. Toulmin. Onions were large, but in nearly all cases unsound. The best Peas shown consisted of Supreme, Veitch's Perfection, Omega, Ne Plus Ultra, and Connoisseur. Magnum Bonum Potato was also generally good. In the miscellaneous exhibits Mr. J. Willis of the Rothamstead Laboratory, the courteous Secretary of the Society, showed forty admirably mounted botanical specimens of dried British plants, evincing great neatness in manipulation. The Judges testified their appreciation of his work by awarding an extra prize. Mr. J. Watson of St. Alban's showed a very simple and cheap suspension

Watsen of St. Alban's showed a very simple and cheap suspension boiler, a great improvement on the old wedge-shaped apparatus. The boiler is said to be safe and lasting, and so it appears, and is said can be easily kept going for twelve or fourteen hours without attention—a veritable boon to amateur stokers. The management of the Memoral of the Memo ment of the Harpenden Show was unexceptional, and the Show as a first attempt a success. I trust it may be so financially, but this has indeed been a bad season for the experiment of a new show when so many of the old societies will, from want of funds, be compelled probably to close their doors.—T. LAXTON, Bedford.

THE ROSE ELECTION.

I SHALL be glad to receive all replies to the two questions at the latest by the 27th of September. I repeat the questions. 1, Newer exhibition varieties. Name the best thirty-six Roses for exhibition purposes introduced since 1871, not including that year; distinguish the best and second best twelve. 2, Name the thirty best garden Roses for all purposes, distinguishing the best and second best ten.-JOSEPH HINTON,

NOTES ON VILLA AND SUBURBAN GARDENING.

DAMP foggy mornings and shortening days warn us that the DAMP foggy mornings and shortening days warn us that the winter is again approaching, although we can truly say that as yet we have had no summer; it is now too late to expect any, and it is necessary to make preparations for another year, which we all hope may be drier, brighter, and warmer. Flower beds have not been so bright and gay as usual, the Potato crop has in many instances been very nearly destroyed, Vegetable Marrows have not set freely, a total absence of ripe Tomatoes, French Beans very late, and many other things entirely out of season. Notwithstanding these drawbacks we must commence again, and the commencement of a new year in the garden begins with the commencement of a new year in the garden begins with the autumn. It is before the summer occupants are removed or destroyed that we should note the faults and failures of the past with a view to finding a remedy in the future. It is much easier to learn this in the garden by actual observation than anywhere else. Those combinations of colours which are most pleasing should be noted. These are minor points, which if carefully done should be noted. These are minor points, which if carefully done now will save an amount of labour, thought, and time another year. Cuttings of most plants may yet be taken off, and if placed in heat will strike readily. Should there be any fear of frost and the old plants are wanted for another season they should be lifted and placed in the smallest pots it is possible to place their roots in. Those cuttings struck in the open ground should be acted at once. should be potted at once.

GREENHOUSE,—This house should now be prepared to receive the winter occupants. The stages and all woodwork should be well cleaned, and such plants as Ericas, Epacrises, Azaleas, Ca-

mellias, &c., that have been placed out of doors to ripen their growths should now be returned. Bulbs for early forcing should be now potted. The small Roman Hysointh is invaluable for blooming towards Christmas, when flowers are very scarce. The flowers, which are smaller than the ordinary Hyacinth, are produced in great profusion, each bulb throwing up three or four spikes of delicately scented clear white blossoms. Five or six bulbe should be potted in a 6-inch pot. Light loam, plenty of sand, and rich leaf soil or dried cow manure is suitable. Place the pots in a frame or near a wall, and coverthem over with coocanut fibre to the depth of 4 or 5 mohes. In the course of a month if examined the bulbs will be found to have commenced growing.

The strongest should then be removed to the greenhouse for a few days prior to introducing them to a warmer structure to accelerate their flowering. If cut blooms are required a number of bulbs may be placed closely together in shallow boxes, and when in may be placed closely together in shallow boxes, and when in bloom may be moved to a cool greenhouse or conservatory to cut as required. If a good display of Hyacinths is desired to follow the Roman the single varieties are, as a rule, by far the best to depend upon. Many good varieties are to be purchased tolerably cheap. The following are all reliable varieties, and as some of them are naturally earlier in blooming than the others they will form an uninterrupted succession:—Alba Maxima, Baroness Van Tuyll, Grandeur à Merveille, Madame Van der Hoop, and Queen Tuyll, Grandeur à Merveille, Madame Van der Hoop, and Queen of the Netherlands. Of the various shades of blue, Argus, Baron Van Tuyll, Charles Dickens, Grand Lilas, Couronne de Celle, Leonidas, Marie, and Mimosa. Of single reds, Gigantea, Mrs. Beecher Stowe, Norma, Ornement de la Nature, Solfaterre, and Von Schiller. The above are chosen principally for their cheapness. The whole of them will, if good bulbs are received and grown well, throw up handsome flower spikes, more particularly the blue varieties. For eighteen varieties for exhibition the following may be selected — Fabiola, creamy nink: Gigantea, delicate grown well, throw up handsome hower spikes, more particularly the blue varieties. For eighteen varieties for exhibition the following may be selected:—Fabiola, creamy pink; Gigantea, delicate rose; Macanlay, rose, with carmine stripe; Von Schiller, deep salmon pink; Alba Maxima, pure white; Grandeur a Merveille, blush white; La Grandesse, pure white, and the finest of its class; Queen of the Netherlands, pure white; Blondin, silvergrey; Charles Dickens, iliac; Czar Peter, pale lavender; De Candolle, reddish illac; General Havelock, nearly black; Grand Lilas, porcelain blue; King of the Blues, dark blue; Lord Derby, clear azare blue; Ida, clear primrose; and Koh-i-Noor, a semidouble, bright salmon pink. Six good single Tulips are to be found in Joost Van Vondel, Keyzers Kroon, Proserpine, Vermillon Brillant, White Pottebaker, and Van der Neer. Both the double and single varieties of Van Thols and the Tournesols are most useful for forcing. But all these make but a fleeting display when forced very rapidly. They should be removed to a colder house as soon as the flower buds are discarnible. Both the double Roman Narcissus and Paper White are excellent for forcing if potted at once, but Gloriosa, Grand Monarque, Newton, and Soliel d'Or are grand varieties to form a succession. The most important point with all bulbs is to pot them early.

WORK FOR THE WEEK. KITCHEN GARDEN.

POTATOES are in some localities much diseased. Any yet remaining in the ground should be taken up in favourable weather, separating the diseased tubers and those required for planting. separating the diseased tubers and those required for planting. The latter tubers should be placed thinly on a dry floor or on lattice shelves in a cool, airy, and dry shed. The late varieties will not be ready for lifting for some time. The vacant ground may be forked over and planted with early Cabbages, which will be very acceptable as the Potato supply is hkely to be short; indeed, a good supply of greens in spring is sure to be appreciated. Thurning late Turnips must be attended to, and winter Spinach and Onions will require similar attention. The principal object in this department will be clearing the ground of Peas and Beans and destroying weeds. If Lettuce seed was sown as advised in late destroying weeds. If Lettuce seed was sown as advised in late July the plants will now be fit to thin out to about 6 inches distance apart, and if the plants are in the open they should be pricked out in frames so as to become well established before winter, but the lights must not be employed until the weather is frosty. Similar remarks apply to Endive for spring. Lettuces and Endive may also be planted at the foot of walls so as to afford an early spring supply. Onions that have been taken up should be placed under cover and stowed away thinly in a dry room or on shelves, stringing the larger bulbs or tying them in bunches. Take advantage of dry days to tie up Lettuces and Endive and to earth up Celery as required. Sow Radish seed upon a warm border, which with protection in severe weather will afford a supply till a late period. Mustard and Cress must soon be sown under class. be sown under glass.

Forcing Department.—A first sowing of French Beans should now be made in 9 or 10-inch pots. Fill the pots three parts with rich rather strong loam. Place six or eight beans around the sides of each about an inch deep, and stand the pots in a house or pit, the nearer the glass the better. When the plants are above the rim of the pots earth up with some rich compost. The temperature should be 66° at night falling to 55° in the morning;

60° to 65° by day by artificial means, and 75° to 80° with sun and air. Water will only be required moderately until the plants are flowering, when it must be freely supplied, and also weak liquid manure. Osborn's Forcing is one of the best varieties.

HARDY FRUIT GARDEN.

In an ordinary season but little requires to be done in this department at the present time, with the exception of attending carefully to ripening fruit of various kinds. This year the wood continues growing, and must be restrained by frequent stopping. Peaches and Nectarines are growing very vigorously. Shoots intended for next year's bearing should be stopped at a length of about 12 inches, which will to some extent act as a check on the growth, laterals being pinched at the first joint. Although root-pruning under ordinary circumstances should be performed when the leaves are beginning to fall, in seasons like the present it is better done earlier, with a view to check late growth and secure if possible the ripening of the wood. After the fruit is gathered the possible the ripening of the wood. After the fruit is gathered the soil should be removed from the roots of those trees that are growing too vigorously, shortening back some of the strongest roots, and take out a trench parallel with the wall, the distance being regulated by the vigour of the trees. The old soil should be picked out from amongst the roots without disturbing them too much, and be replaced with fresh rather strong loam, to which has been added a tenth of chalk or old mortar rubbish and a has been added a tenth of chalk or old mortar rubbish and a sprinkling of half-inch bones. The trees should be syringed every day for a few days if the weather be bright, and a good watering given the roots after adding the fresh material, mulching the surface with short manure. Plums and Apricots may be ing the surface with short manure. Plums and Apricots may be treated in a similar manner, they being too vigorous for fruiting satisfactorily. It is important that it be done whilst the trees have leaves, so that fresh roots may be emitted before winter ready to support the blossom and fruit in due season. Apples, Pears, and Plums should be gathered as soon as they are fairly ripe. If gathered too soon they shrivel, and if allowed to remain too long on the trees the flavour is deteriorated. Autumnal Raspberries promise well, and will prove exceedingly useful if the weather should be at all favourable. This crop is not so general as it deserves. All that is required is an open situation, the soil well enriched; and as soon as the fruiting season is over the canes should all be cut down close to the surface of the soil, carefully selecting the young canes in spring, cutting away all those that selecting the young canes in spring, cutting away all those that are weak.

FRUIT HOUSES.

Melons.—The latest plants will be showing both staminate and pistillate flowers. The first fruits may remain if the object be to get the crop quickly off, or they may be removed and the fruit on the second laterals waited for, provided the requisite degree of heat is at command. The latter course is advisable where space is not an object and a full crop is desired. Do not earth up the roots till after the fruits are set and swelling. Fire heat will be necessary to maintain a temperature of 70° to 75°, rising with sun heat to 80° or 85°. Be sparing with water, employing the syringe only on bright warm days, and then in the early part of the afternoon. Considerable attention will now be necessary to plants just swelling their fruits in guarding against canker and preventing the cracking of the fruits. Fresh slacked lime applied on the first appearance of canker will subdue it. A lessened supply of water both at the roots and in the atmosphere is the proper remedy for both at the roots and in the atmosphere is the proper remedy for cracked fruits, or cutting the shoot half way through a few joints below the fruit in the case of very vigorous plants. Wet the foliage of plants growing in pits and frames as little as possible, and water only at the roots to prevent flagging. Benew or renovate the linings to finish off the crop directly the heat is found to be on the wane, and employ a covering on cold nights.

Pines.—When exterior conditions are favourable ventilate freely

all Pine structures containing young growing stock, also those in which the plants are expected to provide the spring and early sumwhich the plants are expected to provide the spring and early summer supply of fruit next year. In order to maintain the sturdy habit and healthful appearance which plants assume at this period it will be necessary in conjunction with free ventilation to maintain the heat at the roots steady at about 80°, watering whenever the plants require it, employing weak liquid manure, and instead of sprinkling overhead merely sprinkling the pathways, &c., morning and evening. Except to prevent the temperature falling below 60° no fire heat is necessary. Plants lately potted may be allowed 10° to 15° more heat at the roots in order to stimulate them to renetrate the fresh material Suckers recently started should as penetrate the fresh material. Suckers recently started should as

penetrate the fresh material. Suckers recently started should as soon as well rooted be raised near to the glass, bringing them on very gradually. Fruiting plants should have a night temperature of 70°, and 80° to 90° during the day, closing at 85°.

Cucumbers.—Keep young plants near the glass to ensure a sturdy growth, and pinch out the growing point at the second leaf if the plants are to be trained with more than one stem. It is important that the shoots on the stem in either case be rubbed off until the plants have a clear than the shoots of the stem in either case. plants have a clear stem to the trellis, when they may be allowed to make side shoots for bearing. Continue the preparation of fermenting material where that is employed for bottom heat; manure will require to be turned every three or four days, while tan will only require turning once, and that as soon as it is fairly warmed through. In forming the beds whatever material is em-

ployed tread it well down. Use the syringe sparingly, giving a light syringing only in the early part of the afternoon on bright days, but moderate moisture must be secured by sprinkling in the morning every available surface, and damping down before nightfall. The temperature should be maintained at 70° to 75° by artificial means, falling 50 through the night, and allowing an advance to 80°, 85°, or 90° from sun heat, closing at 80°. In pits and frames the temperature must be maintained by renovating the linings as necessary, and employ night coverings to prevent too great dim-nution of temperature during the night. Water very carefully, and sprinkle overhead only on bright days. Keep the foliage thin, frequently removing bad leaves and exhausted growths, and husband the sun heat as much as possible by early closing.

PLANT HOUSES. Greenhouse.—Cyclamens should have every encouragement to make free growth by an intermediate temperature—viz., 55° to make free growth by an intermediate temperature—viz., 56° to 65°, keeping the plants near to the glass, and supplying them with liquid manure. Seedlings established in small pots should be shifted as they fill the pots with roots, or plants as yet in the seed pan should be potted off singly in 8-inch pots as soon as they can be handled. Employ good loam with about a sixth of sand, placing the plants near the glass in a pit or other structure warmer than an ordinary greenhouse. Chrysanthemums should have their final staking and tying. The ordinary upright bush fashion is the best for general purposes, using as many stakes as will be necessary to keep the plants in form. Where good blooms are wanted all the small lateral side branches should be removed from the principal shoots, retaining the latter in numbers propor from the principal shoots, retaining the latter in numbers proportionate to the size of flowers required. Three to five shoots with the flowers thinned to one to each shoot will afford good blooms, or for very large blooms one shoot and bloom only should be retained; even the small varieties should be thinned, the blooms in consequence being finer. Afford plenty of liquid manure but not too strong, and syringe overhead every afternoon if the weather be bright. The principal stock of bulbs should be potted if not already done. The pots should be plunged in ashes under a wall where protection can be afforded from frost and heavy

Azaleas that flowered early will have completed their growth long since. If they have been outdoors they must at once be placed under glass in a light airy position in a cool house, from which they may be removed into the forcing house from a month to six weeks before they are required to flower. Varieties suitable for forcing to produce flowers for cutting and for conservatory decoration and A Remis double white and small second and the suitable shall be white and small second. for forcing to produce flowers for cutting and for conservatory decoration are A. Borsig, double white and sweet scented; Narcisiflora, double white, sweet scented; the old alba, still one of the best for this purpose; Fielder's White; Raphael, double white, sweet scented; vittata elegans, white with red edge; amena and its variety Caldwelli, crimson; Jean Vervaene, rosy pink tipped with white, promises to force well, and is one of the very best Indian Azaleas. Plants subjected to forcing do not require pest Indian Azaleas. Plants subjected to forcing do not require much training or tying, but later plants should at once be tied into the required shape. The plants if placed outdoors must be housed before they become saturated by rain. Camellias that have been placed outdoors after their buds were set should be taken in before there is danger from frost or drenching rain, either of which will cause the buds to drop. If the plants are either of which will cause the buds to drop. If the plants are infested with scale they should have a thorough cleaning, sponging the leaves on both sides, which adds considerably to the appearance of the plants. Any plants that have acquired an early-flowering habit and have the buds well advanced may be brought into flower with a temperature of 50°. Plants that have not the buds so forward as desired for the required time of flowering may be placed in a house which is kept slightly warmer than an ordinary greenhouse, with a little moisture in the atmosphere, but there must be no attempt at forcing, or the flowers will probably fall before they open. All hardwooded plants must be at once placed in their winter quarters. The lighter positions should be given to such as have the softest leaves and make growth in once piacest in their winter quarters. The ingineer positions solven be given to such as have the softest leaves and make growth in the winter, as Boronias, Gompholobiums, Phenocomas, Tremandras, Pimeleas, Leschenaultias, the latter having the warmest position, as the temperature for them should not often fall below 45°, but 40° is sufficient for the general stock. The whole of this case and do not crowd them. class of plants should be kept near the glass, and do not crowd them. Where no separate house or houses exist for wintering Heaths they should be placed at the coolest end of the greenhouse. If Cytisuses well advanced for flowering be placed in gentle heat, 50° being ample, they come into flower quickly and will be very restal and the flowering of Flowering on Flowering of Flowering on Flower useful, and the flowering of Epacrises may be accelerated in the same way. Rogiera gratissima gives terminal and axillary trusses of white sweet-scented flowers at this season, expanding more freely in gentle warmth than in a greenhouse; it is deserving of extended culture.

TRADE CATALOGUES RECEIVED.

Dick Radelyffe & Co., High Holborn.—Catalogue of Bulbs.

The New Plant and Bulb Company, Lion Walk, Colchester.—
Catalogue of Lilies, Orchids, and Dutch Bulbs. R. H. Vertegans, Edgbaston.—Catalogue of Bulbs.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

BOOKS (J. Mitchell).—The "Garden Manual," post free 1s. 8d., contains information relative to the culture of the fruits you name, also of vegetables and florists' flowers.

EXHIBITING FERNS (H. M. P.).—Pteris tremula, being a native of New Holland, is not eligible for being placed in competition in a class for British Ferns.

AGRICULTURE versus HORTICULTURE (J. Morgan, jum.).—By employing the land (attached to your house as a garden) strictly for growing flowers, fruit, and regetables, you would not be engaged in agriculture but horticulture. As to obtaining possession of the land, you had better consult a solicitor.

selicitor.

LAPAGERIA UNHEALITHY (H. L. F.).—If there are worms in the tub they may be brought to the surface by well watering the soil with clear lime water; but the chief cause of the foliage turning yellow is, we apprehend, a deficiency of support. A plant so large can scarcely derive sufficient nourishment from the soil in a tub unless the tub is of an unusually large size. The plant should be planted out, but as that would be difficult, perhaps, on account of the great mass of growth affixed to the root, you might tilt the tub and remove a portion of the bottom so that the roots might pass into the ground below, which should be made good by the addition of turfy loam, peat, and charcoal. If you can do this your plant will regain vigour, but if that plan is not practicable you must then remove as much of the soil from the tub as you can without materially disturbing the roots, and replace with fresh compost, to be top-dressed with decayed cow dung or other well-decomposed manure. Applications of weak and perfectly clear soot water would be beneficial. As you say the tub is well drained, a plant so large can scarcely have too much water during the growing season.

TRITELEIA UNIFLORA (A. James).—This plant is not only quite hardy

TRITELETA UNIFLORA (A. James).—This plant is not only quite hardy when planted on rockwork as you have been informed, but succeeds well on the level. If planted thickly in lines or beds it produces a very pretty effect early in the season. By all means plant builbe of it in your rockery, placing not less than a dozen in each patch, and cover them about 9 inches deep with light andy soil. You may plant them now, or as soon as you can obtain them.

Succular nem.

Succulary Plants for Spring Bedding (A Lody).—Echeverias are greenhouse plants and would be injured if not destroyed by exposure to the frosts and wet of winter and spring. Some of the Semperviums are hardy, such as 8. arachnoideum, 8. fingelliforme, 8. globiferum, 8. hirtum, 8. montanum, 8. pumilum, and 8. tectorum, but these require dry positions and well-drained soil. The last named is one of the hardiest and most useful for spring bedding. Sedums are hardy, and some of them are very useful for ferming dwarf lines, or a close groundwork for beds in spring and summer. A few of the most useful are 8. acre and its varieties elegans and surreum, 8. anglicum, 8. lydium, and 8. glancum.

CYCLAMERS AND SPRING-LUWERING PLAFTS (Law) —The Cyclameter of the spring and summer.

CTCLAMENS AND SPRING-FLOWERING PLANTS (Idem).—The Cyclamen plants will do very well in the pit you name provided you water them carefully and maintain a night temperature of about 50°. It is impossible for us to say in what condition the corms will be that you expect from the Continent, but they will require great care in watering after they are potted, and even then you must not be surprised if you lose some of them. You would succeed much better by obtaining plants in a growing state from an lagitah nursery, or you may raise plants from seed which all English seedsmen of repute supply. The varieties of Cyclamen persicum grown in this country are not surpassed if equalled by any grown on the Continent. The Primulas should be placed at the coolest end of the pit, and the Cinerarias cannot be kept too cold provided they are safe from frost. They succeed much better when standing on a base of moint sahes than on a stage. Not knowing the size and condition of the plants we cannot tell you when they will flower. Cyclamens and Primulas may be had in flower from January cuwards, according to conveniences for growing them, Cinerarias following in March and April.

SHRUBS AND TREES FOR A GARDEN IN DORSETSHIRE (L. F.).—

1, Strubs for a Peat Border:—Let Rhododendrons predominate, taking care to secure a fair proportion of early and late-flowering sorts. Of early, select altaclerense, A. coccineum, White Gem, Nobleanum with its varieties, cancasicum, C. album, C. pictum, Broughtonianum, Welizianum, Vesuvius, ignescens, coriaceum, and Blanche Superbe. Of late, Mrs. John Clutton, John Waterer, Mrs. Holford, macranthum, maximum and its varieties album and purpureum, Alarm, Grand Arab, Barclayanum, geranicides, Lady Dorothy Nevill, Comet, Decorator, Hogarth, Frederick Waterer, Fieur de Marie, Duc de Brabant, Purity, Jenny Lind, Old Port, Mrs. William Bovill, Lady Lopes, Lord John Russell, Minnie, Ne Plus Ultra, Princess of Wales, Star of Ascot, and William Downing. Azaleas you can have in many charming varieties, among which pontice alba should always have a place with such Ghent varieties as Geant des Batailles, Lineata, Julius Cesar, Leopold L., Elector, delicata nova, Admiral de Ruyter, Fanny, Imperatrice, miniata floribunda, versicolor, Splendens, Rubens, Oscar I., Morteri, Unique, the evergreen Azalea amons, and some of the best varieties of Azalea mollis. Then there are Andromeda Catesbeel, A. floribunda, A. formoss, Kalmia latifolia, K. glauca, K. rubra, K. angustifolia, Ledum latifolium, Pernettya angustifolia, Menziesia polifolia, and M. alba, and all the varieties of Krica (hardy Heaths), if you have space. The best are meditermane, Alportii, arborea, the Corniah Heath Erica vagans, vagans alba, carnes, so beautiful in early spring, codonodes, ciliaris, and the varieties of cinera and vulgaris. Carefully arranged masses of these are always attractive, some of them flowering every month, from E. codonodes in January larges.

to R. herbacea in December. Skimmia japonica also thrives best in peat, its bright crimson berries render it very ornamental, also Daphne Cneorum. 2, Flowering Shrubs for Ordinary Soil:—Evergreens—Escallonia macrantha, Berberis Darwinii, B. stenophyla, B. duleis, B. japonica, B. Hookeri, B. Wallichi una, Mahonia aquifolia, Desfontainia spinosa, Daphne japonica, Ligustrum japonicum, Escallonia pterocladon, E. illinita, Viburnum Tinus, V. T. lucidum, Spartium junocum, S. multiflorum, Veronica decussata, V. salicifolia, V. Andersoni, Ulex europea flore-pleno. Deciduous—Deutzia crenata flore-pleno, D. gracilis, Hibiscus syriacus in variety, Hydrangeas paniculata grandiflora, and H. hortensis, Kerria japonica variegata, Pesonia in variety, Philadelphus grandiflorus, Leycesteria formosa, Lonicera odoratissima, Sambucus nigra aurea, Rhus Cotinus, Syringa grandiflora, S. Josiksa, S. vulgaris, Spirsaa Thunbergii, S. arizefolia, S. Douglasii, S. Lindleyana, S. calloca, S. Nobleana, Ribes sanguineum, R. sanguineum album, R. sanguineum aureum, Rubus fruticosus flore-albo-pleno, R. roseo-pleno, Weigela rosea, W. Desboisii, W. varlegata, W. Van Houttei. 3, Flowering Trees:—Deciduous—Tilla europesa, T. microphylla, Robinia Pseud-Acacia, R. hispida, R. hispida macrophylla, R. hispida rosea, Pyrus aucuparia (Mountain Ash), Liriodendron tulipifera (Tulip Tree), Pyrus prusifolia (Siberian Crab), Pyrus Aria (White Beam), Oratægus Crus-galli, C. coccinea plena, C. punicea, C. coxea, C. coxea, C. coxea, C. coxeantha, Cerasus avium multiplex, Cercis situusstrum, Catalpa Kæmpferi, Amygdalus persica, Amelanchier Botryapium, Pavia rubra, P. macroetachya, and Laburnum. Everyreen:—Magnolia grandifora, Laurus nobilis, and Cerasus Institucius. 4, Trees with Handsome Autemnal Foliage.—Acer rubrum, A. polymorphum atropurpureum, A. Negundo variegatum, Fagus purpurea (Purple Beech), Cerasus Padus, Betula alba, Liquidamber styracifiua, Quercus coccinea (Scarlet Oak), Ulmus montana variegata (Variegated Elm), and Esculus Hippocastanum (Horse Ches

FRANCOA RAMOSA (F. T., Dublin).—The Francoas are very variable in the colour and form of their flowers, and by some authors the three known forms are regarded as simply varieties of the original F. ramosa, but others consider them as distinct species. F. ramosa has sessile pinnatial leaves, a long raceme of white flowers, calyx four-parted, petals four, stamens eight, and stigma four-lobed. Probably your plant is one of the two following—F. appendiculate, large leaves, pinnate at the base, raceme of pale pink, flowers densely crowded near the apex. This most resembles the one you describe. F. sonchifolia, looser raceme of larger and purplish flowers with a red line down the centre of each petal.

PRIMULAS AND CYCLAMENS (J.B., jun.).—The flowers sent, Williams's Prince Arthur, rosy crimson, semi-double; Suttons' Ruby King, ruby crimson, are very fine, the white is also good. They represent excellent varieties admirably grown.

DOUBLE LILIUM AURATUM (T. B. Dolby).—The flowers sent indicate the gradual transformation of stamens to petals that characterise double flowers. Four of the normal six stamens are partially converted into petals, but in a very irregular and deformed manner. Possibly the seed of this plant might give rise to plants bearing flowers approaching still closer to the true double form. Try the experiment.

PICEA PINSAPO UNHEAUTHY (J. Byron).—We do not advise you to prune the ends of the branches as a remedy for preventing the growths in the interior of the tree dying. The tree, if it is not suffering from stagnant soil, does not derive the support that it needs. If you can remove a portion of the surface soil for a considerable distance round the stem (further, indeed, than the branches extend), and replace with fresh soil and decayed vegetable refuse, and surface this with manure, the specimen will probably regain its lost vigour and again become ornamental.

regain its lost vigour and again become ornamental.

Fungus on Roses (E.W.).—Your Roses appear to be attacked by the orange fungus, to destroy which dissolve 2 ozs. of blue vitriol in hot water, and then add two or three gallons of cold water, and with this sponge the foliage or syringe the trees. As the fungus, however, is principally on the under sides of the leaves, syringing is not effectual unless special care is taken to apply the solution to the parts affected. Three or four ounces of soft soap dissolved in a gallon of water and similarly applied will also check the spread of the fungus. Enrich the soil if needed by applications of farmyard dung or liquid manure to promote a stronger growth of the Roses.

Stour for the Green of the contraction of the stronger of the contraction of the contr

STOVE FOR GREENHOUSE (C. C. K.).—We do not know to what stove you refer. One apparatus which we noticed was, as we subsequently announced, withdrawn from sale. We do not know of a stove that would satisfactorily heat a conservatory 26 feet long by 16 wide; but as the one you have "answers well so long as it is attended to," cannot you obtain a larger stove of the same kind that would "keep in all night?" If anyone who has had experience of a stove that has been found to answer requirements similar to yours, we will readily publish particulars of it if communicated.

PEARS CRACKING (A. B. C.).—As the fruit on the two trees "always crack," you had better carry out your proposition of destroying the trees and planting others. Beurré d'Amanlis and Louise Bonne of Jersey are two free-growing, good, and hardy varieties. They succeed well on the Quince stock, and are suitable either for growing as pyramids or espaliers. The variety you have is, we think, Souvenir du Congrès, a seedling from Williams Bon Chrêtien.

RRICAS AND EPACRISES (Iden).—For flowering in the late autumn months, such species of Ericas as hyemalis, gracilis, caffra, and colorans are amongst the most useful for decorative purposes. E. exudans, E. pellucida, E. decora, and E. discolor also flower late in the year. A few good early-flowering Epacrises are Vesta, Viscountess Hill, Lady Panmure, The Bride, Alba odorata, and hyacinthifiora rosea. Good later-flowering sorts are Walkeri, rubella, fulgens, Fairburnians, hyacinthifiora candidissims, and courascens. These, however, will not flower before Christmas, Primulas, Cytisuses, dwarf Chrysanthemums, perpetual Carnations, and Solanums are attractive before Christmas, and at the same time are comparatively hardy. By potting bulbs at once of Roman Hyacinths and early Paper White Narcissuses they will flower late in the year.

GRAPES SHANKING (R. H).—Various theories have been submitted on shanking, but it is doubtful if the subject is yet fully understood. Shanking is an ulceration or gangrene attacking the footstalks of the bunches, and appears to be occasioned, like shriveiling, by the temperature of the soil being too much below that in which the branches are vegetating, and consequently the supply of sap to the Grapes is much diminished, and the parts which thus fail to support immediately begin to decay. This is an effect always the consequence of a diminished supply of sap, apparent either in the leaves, flower, or fruit. The coldness of the soil causes this torpidity in the action of the root, and this, perhaps, at the very period when the greatest

demand is made upon it to sustain the excessive perspiration which is going on in the leaf, and to furnish fresh matter for elaboration, to both which ends it is frequently quite inadequate owing to drenching rains. If the young fibre be examined at such inclement periods it will be found somewhat discoloured, and in some cases quite rotten. Shanking, we conceive, is generally caused by the unnatural disagreement of temperature between the root and top, independent in the main of the question of moisture. It generally occurs with Vines which have been somewhat forced; seldom on open walls, seldom with Vines forced in pots or tubs. Vines that produce a mass of healthy fibrous roots near the surface and are in other respects well managed, and if a congenial relative temperature to the roots and foliage is maintained, are rarely disfigured by shanked berries. Vine borders are often made too rich, light, and large at the first, and a few long and strong succulent roots are produced instead of a multiplicity of fibres, as is the case when borders are made firmer and are increased in size yearly as the roots require more space and the Vines more food.

HELIOTROPES FROM SEED (A. S.)—Seedlings usually grow much more

require more space and the Vines more food.

HELIOTROPES FROM SEED (A.~S.)—Seedlings usually grow much more strongly than cuttings, but your plants appear to be exceptionally luxuriant, the leaf sent being 7 inches in length and upwards of $3\frac{1}{6}$ inches in diameter. Had the plants been grown in small pots and placed in a very sunny position in the open air they would probably have flowered. We should strike cuttings of them at once, winter them on a shelf in a rather warm greenhouse, and pot them off in spring, keeping them in small pots until they show their flowers; then place them in larger pots or plant them out. You can also keep the old plants if you prefer, but you could probably occupy their space more profitably, but do not destroy them until the cuttings are rooted. If the weather continues fine your Grapes will ripen, but if dull days ensue employ more fire heat. The practical lesson you have had in thinning-out the berries will be of more value to you than a page of instructions. No precise rules can be laid down for thinning Grapes, as so much depends on the varieties grown and the condition of the Vines.

PIPING FOR HOUSE (C.~Ee).—We always advocate a liberal quantity of

PIPING FOR HOUSE (C. Eve).—We always advocate a liberal quantity of piping, as the requisite temperature can then be maintained without overheating the pipes, which means an undue expenditure for fuel, and a temperature not congenial to vegetation. One hundred feet of 4-inch pipes would enable you to maintain a temperature in the house of 45° to 40° during the severe weather of an ordinary winter, and would keep out frost if the external temperature was only a few degrees above zero. The most expensive mode in the end of heating houses is unduly restricting the quantity of piping.

quantity of piping.

ROSES AND LILIUMS (Mrs. H).—Nearly all the Liliums will grow well in partial shade provided the soil is good and well drained, and at the same time is not dry in summer. You cannot do better than select such of the inexpensive varieties that are offered by nurserymen. Roses do not grow well under trees. You may order what number you require of the stronggrowing Hybrid Perpetuals and try them, or state your wants to a nurseryman and he will send those best suited for your purpose. You do not state the number you require, so that we cannot give a list of either Lilies or Roses. Some of the Lavateras are annuals, some blennials, and other perennials, and we cannot tell to which section yours belong without sesing a flowering specimen.

Specimen.

CLIMBERS FOR NORTH-EAST ASPECT (Berkshire).—The Virginian Creeper will thrive admirably and will cover the wall quickly, but it is deciduous, as also is the ornamental Ampelopsis Veitchii; both are quick grovers. Such Roses as Gloire de Dijon, Amadis, Bennett's Seedling, Dundee Rambler, and Felicité Perpetué would all grow freely in good soil and cover space quickly, as also would such Loniceras (Honeysuckles) as flexuous, brachypoda, pubescens, and sempervirens. Clematises such as montana and fiammula, as well as the fine hybrids Jackmani, Prince of Wales, Star of India, Rubella, Lady Bovill, Miss Bateman, and several others, would grow and flower well. Some of the lytes are also ornamental, and the bright yellow Jasminum nudiflorum succeeds well on a north aspect.

Lioux for Depunys (F. 1). The following as general the most mortus.

VIOLAS FOR BEDDING (F. J.).—The following are some of the most profuse and persistent bloomers:—Bluish Purple—Alpha, Queen Victoria, Tory, and Blue Bell, very free. Purplish Violet—Beauty of Clyde, Cornuta Perfection, Lady Diana, Admiration, and Waverley. Yellow—Dickson's Golden Gem Lutea grandiflora, Sovereign, and Yellow Boy. White—Pilrig Park, Pearl, Purlty, and Nonparell.

GATHERING PEARS (E. Davenport).—Such fruit as you have sent is not by any means ready for gathering. It should remain on the trees until the kernels assume a chestnut colour, or until the fruit when raised by the hand separates readily from the tree without breaking the stalk. Pears cannot be named in a hard green state. The plant is Euphorbia Lathyris, the Caper Spurge.

Spurge.

FRAMES FOR FLORISTS' FLOWERS (J. G. S., Leves).—Brick pits about 6 feet wide, 1 foot high in front, and 2 feet high at the back, are valuable adjuncts to any garden, not only for preserving comparatively hardy plants in the winter, but for growing more tender plants in, also such crops as Cucumbers in the summer. Such plants as Carnations, Pansies, Phloxes, Chrysanthemums, and various others, including Auriculas, may be safely wintered in such pits, the plants, except those last named, being grown in the open air during the summer. We should not have any concrete bottoms, but should have the foundations of the brickwork 18 inches or more below the ground level and fill in with rubble to the requisite height, surfacing it with coal ashes. The water would then pass away freely, and the pots could, if necessary, be partially plunged in the ashes, and thus their roots would be protected. In the summer the pits could be deepened so as to accommodate taller plants or crops. The pits should face the south. For Auriculas moveable frames should also be provided, as a southern aspect except in winter is unsuitable for these plants. In the summer Auriculas require a very coal position, such as the north side of a building, while in the spring an easterly or southerly aspect is preferable, except when the flowers commence expanding, when the plants must be placed in a shaded position. The plants except in summer are best placed on stages of wood, which can be realily formed in the frames, and the plants should be close to the glass. We should thus have both pits and frames, having ashes in the former, placing a few boards on the ashes if any plants required a dry base at any time, and wood shelves in the frames for the Auriculas. We do not know of any special mode of obtaining plants. Private growers frequently exchange plants, but do not namally self them below their current value.

POTTING SHED (An Irish Subscriber).—We readily answer all questions on gardening subjects that are submitted to us in an intelligible form. Your question as put now is totally different from that of last week. Estimates

of cost we do not give, and it appears by your question now before us that you do not desire us to do so, but simply wish to know "what a gardener would require in a lean-to shed, say 20 by 10 feet, and whether it would be more suitable to glaze the roof like a greenhouse, or slate it?" This question is answerable, the other was not. A glass roof is not necessary for a shed of the width named even if it faces the north; ample windows in the front wall will admit all the light that is required. The potting bench, about 3 feet wide, should be placed near a window, and should be made of 2½ inch planks planed smoothly on the upper side; benches made of thin boards are always unsatisfactory. A shelf next the wall over the bench is very useful for labels, nails, and shreds, paint, strings, whetstones, pegs, and other small articles in constant request. In the back wall stout pegs should be fixed at proper heights for various tooks used in the garden, and others should be placed in a convenient position for water pots, baskets, &c. Three or four bins should be formed on the floor, the one for loam being much the largest. This provision for soil is very important. If the height of the shed permits a few strong beams should be placed across from wall to wall to support boards for forming a loft, which would be valuable for mats, nets, brooms, stakes, &c.; and nails should be driven into the rafters on which could be hung Onions, herbs, and other products and articles. Drawers and boxes for roots and seeds are necessary, their size and number depending on circumstances. Further, means should be adopted to render the shed frostproof during severe weather; a row of hot-water pips, a fireplace or portable stove will answer. Various roots can then be preserved, plants can be potted, and much other work done during inclement weather. By adopting the mode of arrangement suggested, subject to such modifications that you doem necessary, you will have a shed of great useful-

ness. The floor may be of bricks, stome slabs, or asphalte.

SOWING GLORIOSA SUPERBA (D. Wilson).—Sow the seed early ners March in a compost of equal parts peat, loam, leaf soil, old cow dung, or well-decayed manure, and sand, covering the seeds about a quarter of an inch deep, and place the pots in a hotbed of not less than 75° nor more than 90°. Keep the soil moist, but not wet, and when the seedlings are up let them have abundance of light; keep the young plants near the glass, but still in bottom heat. They must be kept moist at the roots, and have a moist atmosphere, a temperature of 80° to 70° at night, 75° to 85° by day, or 90° with sun and air. When the seedlings can be well handled pot them off singly in 3-inch pots, and return them to the hotbed, shading for a few days until they have recovered from the potting, them admit air, and expose to light. When the pots are filled with roots shift the plants into 5-inch pots, which will be sufficiently large the first season, keeping them in the hottest structure you can command, with a moist atmosphere, up to September, when the moisture should be diminished, and the plants dried off before winter, and kept dry until March. Then shake away all the soil and repok, covering the bulb about an inch or so with soil. Place the plants in a hotbed, and do not give any water until the bud appears above the soil. Rencourage growth with strong heat and moisture, training as it proceeds. The plant will succeed in the greenhouse after it has advanced to the flowering state. When the leaves are turning yellow coase watering, and when the flowers are completely decayed place the pots where they will be dry until the following March.

NAMES OF FBUITS (A. Z.).—The Annle is Cellini, the Pear we think

NAMES OF FRUITS (A. Z.).—The Apple is Cellini, the Pear we think Beurré de Capiaumont. Fruit should be ripe when sent for identification.

Beurré de Capiaumont. Fruit should be ripe whea sent for identification.

NAMES OF PLANTS (S. E. W.).—Achilles Ptarmics flore-pleno. (A. C.).

—1, Cupressus sempervirens (Upright Cypress); 3, Thuja Warreana; 3, T. orientalis, or Chinese Arbor-Vitze; 4, Stachys lanata; 5, Clethra siniolia; 6, Myrica cerifera. (Clitton).—Cineraria scanthifolia. (Hornotexch).—The specimen resembles Impatiens Noli-me-tangere. (W. C.).—Cinscinuga Serpentaria. (L. B.).—1, Cnicus arvensis (Creeping Plume Thistle); 3, Cnicus palustris, or Marsh Plume Thistle; 5, Polygonum avienlare; 4, Bartaia odentites (Red Bartsia); 6, Hieracium sabaudum (Shrabby Hawkweed); 5, Crepis biennis (Rough Hawksbeard); 7, Lapsana communis (Common Nipplework). (Rosa).—The smallest flower is probably Neottia sestivalis, but in the absence of root and leaf it is scarcely recognisable. The other is probably Dendroum chrysanthum, but the specimen is very imperfect. (3, Turnbul).—1, Specimen insufficient; 2, Francos ramosa; 3, Pilea miscosa. (String).—1 appears to be an Ixia, but the specimen was not sufficient for identification; 2 resembles a Veltheimia, but we cannot undertake to name plants from a single small flower alone. (J. P.).—1, Calamintha officinalis; 2, Santolina incana; 3, Sedum carneum; 4 resembles Malva moschata siba; 5, Silene perfoliata.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

CULTIVATION AND USAGE OF GORSE OB FURZE.

Gorse or furze is found in almost every district of the United Kingdom, and although it commonly grows in its wild and uncultivated state upon the poorest and most barren lands, yet it has been in use as food for horses and cattle from time immemorial. In Wales—according to the most reliable evidence obtained from the farmers of the counties of Carnarvon, Anglesef, and Denbigh—it has been used principally for the feeding of horses, either by itself or in conjunction with other provender, and in seasons when the hay has been damaged it has proved a most valuable substitute for it. At the same time, and particularly upon farms where no roots are cultivated, gorse is the best provender for milch cows in the winter months, and the results of its usage have been most satisfactory. It gives to the milk and butter a fine cowslip colour and a rich flavour. Those who have applied it to this purpose hold the opinion that cows yield

more profit than when fed with the best hay, or even with roots, such as Swedes, turnips, or mangolds. The practice of feeding sheep with gorse has hitherto been somewhat limited. This has chiefly arisen from the attention of the small or peasant farmers not having been directed to the keeping of sheep stock. In those cases, however, when the experiment has been made in conjunction with turnips, hay, &c., sheep have been found to eat it freely, and improve in condition rapidly. It is in feeding horses, however, that gorse has been most generally and usefully employed, particularly by the small farmers—not only in Wales, but Ireland, Scotland, and also in France and Belgium. In ordinary seasons the grass and other produce of many of the small farms as they have been cultivated would barely suffice for the horse or horses employed upon them.

The cultivation and careful management of this plant, common as it is, deserves the greatest attention, and presents to all classes of farmers advantages, some of which we propose to enumerate-It grows luxurisatly on the thinnest, the coldest, and apparently the most sterile soils. It may be cut as circumstances requireat one year's growth as well as at two. With moderate care in its culture, and by keeping it protected from the bite of sheep, cattle, &c., it will produce in one year's growth from 8 to 10 tons per acre of good succulent food; but in case it is out every second year it will yield at the rate of from 12 to 15 tons per acre. The gorse, however, at two years' growth is a very different article from that of one year's growth, because a portion will have become hard and wiry, and in proportion as the woody fibre has been established so the nutritious portion of the plant has been used in forming it, and its value as food lessened in proportion. Although we have found that gorse will grow under the greatest disadvantages as regards soil and aspect, still it will grow more luxuriantly and produce much heavier crops, even on the poorest land, in a warm aspect and mild climate. Many poor sands, gravels, or chalk hills now furnishing but scanty food in pasture for sheep or other stock would, under gorse cultivation, yield abundant crops of great value compared with the little herbage produced under ordinary circumstances.

We must now refer to the cultivation of gorse so as to insure as nearly as possible a regular plant. There are two or more varieties of gorse. The small brown variety, commonly seen on heaths and moors, is of little use. It is to the French variety that we look for the production of full crops, and somewhat large quantities of seed are annually imported from France and Belgium and it is now selling at 1s. 6d. per pound. The best time to sow the seed is in March or April, and when sown broadcast amongst com, as is often done, 16 or 18 lbs. of seed will be required per acre; if drilled 13 or 14 lbs. will be sufficient. This mode of culture is similar to sowing clover with Lent corn, which always suffers if the corn is bulky and laid, and gorse will suffer precisely in the same way. There is, however, another plan of sowing similar to the cultivation of lucerne, in which case it is drilled at intervals of 15 inches between the rows for the purpose of hand-hoeing, or at intervals of 18 to 22 inches for the advantage of interculture by horse-hoeing whilst the plants are young, for they are sure to suffer nearly as much as young turnip or mangold plants if overrun with weeds or couch grass, There is also another mode of obtaining a good plant of gorse, and, although it may be more expensive, it is probably the surest way of obtaining early maturity. It is by sowing a patch of garden ground in the month of March and setting out the plants in clean and well-cultivated ground in the month of September, similarly to the planting of cabbages. The plants may be set at about 12 inches apart in the lines, and 18 inches between the lines. This plan will yield a crop fit for cutting as cattle food in November of the following year, but during the summer the land should be kept free from couch and weeds. Each of these modes of sowing has advocates, but it is found that in the broadcast, or even in the drilling system, the seed does not usually vegetate regularly, probably from the circumstance of some of the seed being new and some several years old. This will undoubtedly cause the seed to start at different periods, the newest seed always

being the first in growing; we therefore commend the system of planting as being the safest plan of obtaining and retaining a regular plant of gorse. The mode of cutting the crop yearly is very cheap and simple. Every cutting should be done with the scythe, and by cutting close to the ground there will be no old hard stems to contend with. If, however, the crop is only taken at two years' growth the cutting is more difficult. On many soils the plant is indigenous, and in case we have any rough land hitherto overgrown with strong gorse this land, after grubbing-up the old stumps, will be sure to become thickly planted with young gorse the first year after grubbing, and may thus be converted into a field for the growth of food for horses, cattle, dc.

One of the reasons why gorse has not attracted more attention as food for stock is in consequence of the difficulty of reducing it into a state fit for food, by breaking down the prickles and points on the stems of the plants. The old-fashioned method of chopping the stems and beating with a mallet on a block was succeeded by a plan whereby the stems were passed through an ordinary chaff cutter, which if carefully done would be sufficient to induce horses to eat it; but not so the cattle. It was therefore necessary, when required to feed cattle or sheep, to crush it under heavy revolving stones on a platform by horse power. We have, however, now a machine for use by which even gorse of two years' growth may be manipulated if required. This machine is called a Gorse Mas-ticator, and was exhibited at the late Show of the Royal Agricultural Society at Kilburn, where it received a special silver medal. This new machine is sold by McKenzie & Sons of Cork, and will reduce the most stubborn gorse to a pulp, so that any stock will eat it readily; but owing to the heating and forcing effect of this food it is usually given in conjunction with hay or straw chaff for horses, and with roots of some sort for cattle and sheep. We must new call the attention of the home farmer to the growth of gorse, for upon any poor portion of the farm or any hilly rough ground it may be turned to account, and especially where game is reared by the proprietor or occupier of the property, for in such a case the gorse field would be sure to attract game and furnish capital breeding ground, especially for partridges, as it lies quiet all the spring and summer down to the month of November, when the gorse is cut. If required for the protection of rabbits it may be cut in patches every two years, thus leaving intervals between the two growths for the purpose of facilitating the sport of shooting, and still the advantages and value of the gorse for feeding purposes may be maintained. Farm horses may be allowed daily about 40 lbs. mixed with a little hay chaff; cows may be allowed the same quantity, with about 10 lbs. of roots and straw chaff, bran, or oatshells mixed daily. This food should and straw chaff, bran, or ostshells mixed daily. This food should be prepared only as required for use, for it will ferment and turn sour if prepared beforehand. The clippings of gorse fences are sometimes used as cattle food, and the sloping banks often found in hilly districts as well as the banks of railway cuttings may be turned to account by the growth of gorse. Various instances can be adduced where a number of horses let for hire, and large dairies of a hundred and upwards of milch cows, have been maintained in capital condition during the winter months from November 1st to March, with prepared gorse in admixture with other food.

Analyses by various chemists have been taken, but that given by Mr. Lawes and Dr. Voelcker in comparison with other food is the most important. As follows—

Name of Food.	Flesh- formers.	Fat- formers.	Name of Food.	Flesh- formers.	Fat- formers.

WORK ON THE HOME FARM.

Horse Labour.—Horses will be as yet employed in connection with the harvesting, carting, and stacking the crops of corn and wiles and also the second cuttings or late crops of hay. The next pulse and also the second cuttings or late crops of hay. brings and also winter vetches; 80 lbs. of seed per acre for the former, and 2 bushels mixed with 1 bushel of winter oats for the latter, would be none too much seed under present circumstances and prospects. At the same time the autumn cultivation of all land intended for roots next year should be continued whether the harvest work has been concluded or not, and where the horse power on the home farm is insufficient for this steam power should be resorted to immediately. Every day of dry weather at this late period of the year is of the greatest consequence, and where steam power is not maintained upon the farm it should be hired. Several seasons past must have taught the home farmer lessons which he should not forget-that is, that where autumn tillage has been neglected clean fallows for roots could not be effected in the spring, especially for early sowing with mangolds and other roots. We have during the past week or two had abundant opportunities of seeing the result of a succession of bad seasons for fallowing the land on the mixed and strong soils; the fields in most instances are ex-tremely foul with couch, watergrass, and the various weeds of the farm. This is more especially the case where autumn fallowing has been neglected, and where farmers have neglected to prepare the land for roots until the spring of the year, but is nowhere so

visible as upon farms cultivated under the four-course rotation. The reason of this is fully apparent when it is considered that the root land when the season is unfavourable cannot be cleaned as the fallow, in which case there is no other opportunity for eradicating the couch grass until the land is again under cultivation with roots, unless it is done by forking out the couch amongst the roots, or, as a last resort, instead of taking a second crop of clover a bastard fallow, as it is termed, is made after the hay crop has been taken and before sowing the land with wheat. Upon the generality of soils, however, this practice is often prejudicial to the wheat crop, for the late fallow makes the land too hollow, and when it settles down in the winter it oftentimes leaves the roots of the wheat plants comparatively bare; the crop then frequently has not sufficient root hold, and the wheat falls before harvest. This statement, based upon our own experience, should teach the home farmer that autumn cultivation of the fields intended for roots the next year should be done by fallowing or surface cleaning in the autumn, either by the horse power of the farm or, which is

better, by steam power, because so much more of this work can be done in a given time.

Hand Labour.—Potatoes are now being taken up, but the early varieties, particularly the Early Rose, have suffered much from the disease when they have been allowed to remain in the land. The only exception we have seen is where the haulm was cut off The only exception we have seen is where the hailm was cut off as soon as it turned yellow, and in such cases the roots have proved sound. It is yet too early to dig the late varieties, because it is quite impossible to say what portion of the tubers would rot if stored before they are ripe. When the haulm is affected by disease it is best to let the potatoes remain in the ground until the month of October, in which case any tubers affected will have decayed, and the remainder will generally do well in store. Cattle intended for Christmas will not improve much in condition from this time on the neatures unless some grass has been especially this time on the pastures unless some grass has been especially reserved for them, and even in that case they should go into the house or yards at night time and receive some cake, cracked beans, house or yards at night time and receive some cake, cracked beans, or maize, dc., or be put into the boxes or stalls for winter quarters, as the nights are becoming chilly for the animals. The dairy cows, too, should have some assistance beside the grass, as the pastures are becoming stale and short of grass; and to enable them to continue to yield a full quantity of milk they should receive a little hay at night, or, what is better, green fodder in the racks at milking time if such has been provided, consisting of clover, late trifolium or watches and man wixed, but up the because of providers. trifolium, or vetches and rape mixed; but in the absence of assistance of this kind the yield of milk will rapidly diminish. Weaned calves should now come into hovels at night time and receive some chaff with pulped roots, but steer calves intended for fattening early should be kept in entirely and fed upon early turnips, chaff, cake, and beans cracked; a small portion of inferior wheat crushed would answer now, the samples are so light, mixed with other food. This is the heavy would great for house when crushed would answer now, the samples are so light, mixed with other food. This is the heavy working period for horses when they are just going off the feeding with clover, and it should be quite understood that it is a bad plan to change suddenly from green food to hay or all dry food of any sort. It is much better for the animals to get some roots with hay, chaff, &c., and an increased allowance of corn until the heavy work of the autumn months is finished. Colts will now be weaned, and when taken from the mares should be placed in well-fenced paddocks with a hovel attached for feeding them in. The best food they can have is white carrots cut with Gardener's cutter, and bean or maize meal mixed with the roots, and good park or meadow hay well saved ad libitum. Where the manure has been laid out for wheat either upon the fallows or lea ground it should be spread immediately, in order that it may be the more readily covered in when the land is ploughed, for if allowed to lie long in heaps it is sure to make the corn grow irregularly and injure the yield of grain.

INDIA AS A WHEAT-PRODUCING COUNTRY.

A REPORT on Indian wheat by Dr. Forbes Watson has recently been published by command of Her Majesty and presented to both Houses of Parliament. This subject, which is one of great importance, has been treated in a most exhaustive manner, and the report may, and no doubt will be, read interestingly by the landed gentry, farmers and capitalists of the kingdom.

In accordance with a resolution of the Government of India upwards of a thousand samples of wheat were sent to the India Office for examination—by far the most complete collection of Indian

Office for examination—by far the most complete collection of Indian wheats ever brought to this country. These samples were submitted to critical examination, and their relative values were assessed and compared with the current values of the produce of the chief exporting countries and with the current quotations of English wheat. Divided into five grades, it was found that of the best white wheats from India 101 samples were of superior quality—valued at 44s. to 48s. per quarter of 496 lbs., while only nine samples were inferior and of a value below 87s. per quarter—the average value 41s. 9d. Other classes were of proportionally lower value, yet it is worthy of notice that out of 827 samples 459 were above average value, while 368 were of ordinary or inferior quality, but only 114 decidedly inferior. By a comparison of value of the wheats of the great exporting countries the Indian

produce compares very favourably, only being a little lower than Danzig, Australian, and the best American grades, while it exceeded by 2s. per quarter the average price of English wheat, but in this by 2s. per quarter the average price of English wheat, but in this case, as is explained, home-grown produce was of a low average character. After showing that India is well adapted by such aids and precautions as are suggested for the growth of wheat of the highest quality, and after adverting to the present low level of prices (which have only been reached twice within the last hundred years—viz., in 1835 and 1851), the conclusion arrived at is that India is well adapted for the growth of wheat of the finest quality, and may shortly become one of the chief sources of supply for the United Kingdom.

The relative quantities of wheat grown by different countries is thus estimated:—"The production of the United Kingdom amount.

thus estimated:—"The production of the United Kingdom amount to only about 10,000,000 to 18,000,000 quarters per annum. Austrothus estimated.— The froducion of the Ontest Anguona mount to only about 10,000,000 to 18,000,000 quarters per annum. Austro-Hungary, Italy, and Spain each produce about the same quantity. Germany produces from 15,000,000 to 18,000,000 quarters, and the two countries which produce the largest amounts are France and Russia, each producing from 30,000,000, to 35,000,000 quarters per annum. Both are surpassed by the United States, which produced during each of the past two years upwards of 45,000,000 quarters. No complete statistics exist for India, but the yearly production of the provinces under direct British rule will amount to from 30,000,000 to 35,000,000 quarters, or to the same quantity as that produced by Russia or France. But if the native States in the Punjab, Rajpootana, Malwa, Bundelkund, and Guzerat be added, in all of which wheat is largely cultivated, it will be found that India must be considered as being, next to the United States, the largest wheat-producing country in the world." Much other information immediately affecting the interests both of this country and India is contained in the Report, which is highly worthy of perusal by all who are interested in the important subject on which it treats.

LA FLÈCHE.

FASHION prevails far too much with poultry fanciers. It is FABRION prevails far too much with poultry fanciers. It is true that certain old-fashioned breeds hold their own, as they ought and probably ever will do. Many kinds, however, are tried and discarded without any fair trial, some of them doubtless because they do not answer the particular requirements of the breeder; others because they have been unduly extolled, and being found not to come up to the character given them by some over-enthusiastic admirer are thought good for nothing; others simply because their owner is fond of novelty, and only bought them as something new and uncommon. Among breeds which them as something new and uncommon. Among breeds which we suspect have not had a fair trial are La Fleche. Some twelve we suspect have not had a fair trial are La Flèche. Some twelve or fourteen years have elapsed since French poultry came into vogue in England. Crèves had been known for some time before, but were only occasionally seen in the "Any variety" classes of poultry shows. Suddenly a regular furore for French poultry sprang up; it was much stimulated, if we remember rightly, by the sight of the splendid birds, most of them imported, then shown by the long-since-defunct National Poultry Company, and by Colonel Stuart Wortley. Classes were everywhere given for the three varieties, Crèves, Houdans, and La Flèche, and they took their place as recognised breeds. Handsome Crèves have held their own, though we learn that they, especially the former, have not been improved in utility by the very arbitrary standards of beauty which have been made for them.

La Flèche have almost entirely disappeared from English shows, a few sometimes compete with Crèves, and a few are found in "Any variety" classes, but anything like a good collection of the breed could not, we believe, be made in the three kingdoms. Why is this? We have inquired much and can get no satisfactory answer. We are told that they do not thrive in the English climate. This may be so, but we have great doubt about the truth of the assertion, there is much variences in it too for the

answer. We are told that they do not thrive in the land the climate. This may be so, but we have great doubt about the truth of the assertion; there is much vagueness in it, too, for the climates of Yorkshire and of Devonshire are very dissimilar, and birds which do not thrive in one very probably might in the other. Certainly La Fleche are not beautiful, and probably they are susceptible of cold, and for these reasons we fancy no one has taken much pains with them. They are noble birds, however, when well grown and in fine condition, and though their hornlike combs perhaps look somewhat Satanic, we cannot but admire their glossy black plumage.

combs perhaps look somewhat Satanic, we cannot but admire their glossy black plumage.

As they are eminently a breed for use and not for fancy, we shall not give any minute particulars as to their exhibition points. La Fieche are a large breed, somewhat long on the leg, but still not deficient in breast; their plumage is tight and of a glossy black throughout; they have no comb in the ordinary sense of the term, but two fleshy horns; their legs are slate colour; their flesh is white and very juicy. The famous poulades of the Parisian markets are almost always of this breed. They are fair layers of large eggs, very like those of Spanish fowls, to which they are evidently related. There were immense and excellent classes of them at the Paris Exhibition, though few of the birds individually equalled the finest specimens we have seen at English shows. A few years ago very fine birds were exhibited by one or two fish breeders, but the grandest specimens we have of late seen are

those belonging to Mr. De Faye of St. Helier's, Jersey. An old and the moulting sickness comes about. As a natural consequence cock from this yard, which carried off the first prize and a cup at the weakness flies to the extremities.—Geo. J. Barnesey. the last Jersey Show, was a truly magnificent bird, and though at least six years old he was in full and good plumage—a sign of great strength of constitution at that age. We have since inquired the weight of the bird, and soon after a long voyage to an English show, from which he suffered much, he weighed 11 fbs. 10 css., and the hen which went with him 10 fbs. 2 css.! Their owner keeps all three French varieties, and therefore is an impartial judge of their merits. He wrote to us in April: "My Le Flèche hens have laid all the winter, and I have not found an egg unfertile, and yet the winter has been one of the coldest and most severe we have had for years, and I consider the breed one of the best either for laying or eating; I find them more hardy and better able to stand the cold than the Houdans or Creve-Cours. I keep the three breeds, and have given them fair trials. The reason why many are discouraged with La Fleche in beginning is simply owing to the way they feed their birds; I find by experience that they must have a good and generous diet at all times, but above all a good warm meal in the morning, and if confined a certain quantity of animal food."

Such being the opinion on the breed given by so good a judge, we should certainly advise those who live in a good climate in the southern or western counties to try La Flèche. Table poultry are terribly neglected in England, and any good addition to our breeds is a boon. When a variety has been let down as this has it generally gets into the hands of a few fanciers whose stocks are probably related; we should therefore recommend that a vigorous cock or two be procured from a good French yard from time to time. With a little care we feel sure that the breed might succeed well in the hands of a careful poultryman.—C.

RHEUMATISM IN CAGE BIRDS.

We have heard of many cage birds becoming weakened in their feet and claws besides those of a correspondent, "H. L. F.," whose birds are not affected with cramp or paralysis, or they would not, as is remarked, be otherwise in good health. There is scarce any wonder at birds being affected considering the damp and changeable weather experienced throughout the summer, especially when so much humour has prevailed and birds have had the use of the bath the same as when the air is dry and sultry. It is not easy to prescribe a remedy without knowing how the inflicted birds have been treated, but generally the first step to take is to remove them into other cages, separating the Canaries, Goldfinches, &c., from the foreign birds. For the first week bathe the feet of the birds in warm salt and water for two or three minutes each time, and before placing them in their cages tenderly rub the claws betwixt your thumb and finger with brandy and salt. At the expiration of the week anoint the claws with almond oil two or three times. Supply a free vegetable diet, such as watercress, plantain seed, and lettuce, plenty of which may now be obtained. The foreign birds may in addition have ripe fruit and grass to eat. Mix with the Canary and white millet seed mustard seed, linseed scalded, rape seed, and groats. When the birds are recovering the use of their claws they will be much benefited if permitted to fly about in a spare open room with branches and rudely constructed perches fixed therein. It is surprising to find

radely constructed perches fixed therein. It is surprising to find how quickly the birds regain strength and pass through their moulting sickness when they have their liberty as suggested. Perhaps a few remarks about perches will be of use. Birds in their free natural condition have the advantage of perches of various degrees of thickness and form. The chief consideration about be that birds should have perches such that they can well grap, so that the muscles of their claws and legs are properly brought into play. The perches in an aviary should vary in con-struction, for those which will be suitable for the larger and stouter claws of many small foreign birds will not be so suitable for the smaller and more delicate claws of Canaries, Goldfinches, Linnets, Sakins, and Redpoles; besides, smooth perches are a disadvantage to birds always caged up, for they have to use them or none, for there is no choice, and thus no relief when all are alike constructed. It is true the branches and twigs of trees are round and often smooth, but they so vary in shape and possess a coating in the shape of bark, which birds can much better grasp and cling to than they can to perches smoothed and rounded to a degree of man they can to perches smoothed and rounded to a degree or niesty with scraping and sand-papering as they are often prepared. No greater proof can be given as to the injury accruing to the feet of birds when their muscles are not brought properly into play than the fact of fowls suffering when having to ever contend with a smooth surface for their claws. There may be a great difference betwixt fowls and cage birds, but still if cage birds only suffer in a slight degree it is far better that Nature be assisted as much as within it is wished that and up a test should be mistigated in a slight degree it is far better that Nature be assisted as much as possible if it is wished that caged-up pets should be maintained in a state of health to afford us pleasure. With such perches as I have above referred to birds lay hold of with more difficulty of maintaining their equilibrium when flying from or delivering themselves from perch to perch. This difficulty robs the birds of confidence and tends to bring about a weakness in their claws, more especially when the system is at a low ebb at the decline of summer

VARIETIES.

THE INCUBATOR TOURNAMENT AT HEMEL HEMPSTEAD.—The following are the results of the trials of the several incubators : Christy's Hydro-incubator.—Number of eggs placed in incubator one hundred, found fertile ninety, unfertile ten. Christy's Hydro-incubator No. 2.—Eggs placed in incubator eighty, found fertile seventy-one, unfertile nine. Howell's egg-hatcher No. 1.—Eggs placed in incubator one hundred, found fertile sixty-seven unfertile thing the home hand on the seventy of the sev placed in incubator one hundred, found fertile sixty-seven, unfertile thirty-three. Howell's egg-hatcher No. 2.—Eggs placed in incubator sixty, found fertile fifty-three, unfertile seven. Cashmore's No. 1, heated by gas, failed. Cashmore's No. 2, heated by oil lamp.—Eggs placed in incubator fifty, found fertile forty-two, unfertile eight. Watson's Scotia, heated by oil lamps.—Eggs placed in incubator sixty, found fertile fifty-four, unfertile

America and Canada. It appears that in the case of cattle the loss is about 8 per cent. of the numbers shipped; while sheep suffer to the extent of only 2 per cent. The heaviest mortality is in the case of pigs, being over 10 per cent. The compilation of these calculations has been carefully effected. They show a great diminution in the proportion of loss since the first establishment of the trade in live stock, at which time the deaths amongst the cattle amounted in many instances to 25 per cent. The decreased ratio is due to the more enlightened means which are now adopted for the comfort of the cattle on the voyage.

— In spite of adverse seasons and the recent bad weather, Messrs. Webb & Sons' seed farms at Kinver present a very healthy appearance. A recent inspection of the principal farms held by this enterprising firm was sufficient to prove what is already well known—viz., that careful culture, good nourishment, and unsparing toil and trouble will do something to mitigate the evils even of bad seasons. With respect to the crops grown by Messrs. Webb & Sons at their various farms this year, we may say that they include over 180 acres of wheat, 146 acres of Kinver Chevalier barles of first three acres of the act this farm acres of the form. they include over 180 acres of wheat, 146 acres of Kinver Chevalier barley, fifty-three acres of oats, thirty-four acres of peas, forty-one acres of potatoes, besides a large acreage of Webbs' Imperial Swede, mangolds, and turnips. The other crops grown at Kinver for seed purposes include Kohl Rabi, carrots, Webbs' new early drumhead cabbages, giant cow grass, thousand-headed kale, improved Italian rye-grass, &c. At the trial grounds we saw growing upwards of 1600 different sorts of flowers and vegetables, the latter including over 100 varieties of peas and 500 sorts of potatoes. We may also say that, apart from the stock seeds grown at the Kinver Hill Farm, thousands of acres are employed in other suitable parts of the kingdom for growing crops of selected cereals, roots, vegetable and other seeds under contract.—(Midland Counties Herald.)

A COMMITTEE MEETING of the British Bee-keepers' Asso-— A COMMITTEE MEETING of the British Bee-keepers' Association was held at 105, Jermyn Street, September 10th, 1879. Present.—Mr. Cowan in the chair, Rev. G. Bartrum, Messrs. Cheshire, Hunter, Hooker, J. P. Jackson, and Rev. H. R. Peel (Hon. Sec.). The minutes having been disposed of, the Chairman said he wished the Association to secure the copyright of Mr. Cheshire's diagram, which he considered ahead of any hitherto published, and had in reference to the matter conferred with Mr. Cheshire, who was willing to co-operate with the Association in the matter, but desired time to complete some points he was still investigating. but desired time to complete some points he was still investigating. but desired time to complete some points he was still investigating. It being felt that some pamphlet suitable to cottagers, aiming at plainness rather than style, was needed, Messrs. Cheshire and Hunter were requested to undertake the preparation of such a pamphlet. Mr. Cowan consented to read a paper at the next conversazione, October 15th, on wintering. The accounts to August 80th were presented, showing an outlay of £337 16s. 3d. and an income of £389 4s. 2d.; balance in Treasurer's hands £51 7s. 11d. Mr. J. P. Jackson stated that he found himself through press of business unable to attend to his spiery so conthrough press of business unable to attend to his apiary so constantly as he could desire, and he wished to place at the disposal of the Committee the only Cyprian queen of undoubted purity in the country, in order that the holder of her might if possible secure from her pure progeny, with a view to the establishment of Cyprians amongst us. Mr. Cheshire, at the unanimous request of the Committee, agreed to receive the queen in the hope of being able to raise queens in nuclei for his brother committeemen. A cordial vote of thanks to Mr. Jackson terminated the proceedings.

— THE Hertfordshire Bee-keepers' Association organised through the Rev. C. Hargrave, an apicultural exhibition on the 11th inst. at Harpenden, in connection with the local Horticultural Society, the success of which was in large part attributable to the kindness and tact of the gentleman just mentioned. The exhibits of honey were good for the year. Mr. John Hoar staged

"a hive of honey taken without destruction of the bees," which the Judge (Mr. Cheshire) at once pronounced to be the result of the labours of two stocks which had been storified and united. This the exhibitor when asked frankly acknowledged; and as the lower hive taken alone was ahead in the competition, he was awarded first, Mrs. Attwood coming second with a good skep, and Mr. H. J. Humphrey third with a similar hive which had been much over-smoked, however, in order to remove the bees. In the driving competition the time occupied by the winners—Messrs. H. J. Humphrey and Charles Sibley—was thirteen and nineteen the driving competition the time occupied by the winners—Messrs. H. J. Humphrey and Charles Sibley—was thirteen and nineteen minutes respectively. The drumming being on the whole much too violent, bees running up the hive side are constantly knocked down again by the too violent bang of the learner in his anxiety to drive them with all speed. The tent seemed as interesting as ever, and was crowded at the manipulation during which Mr. Charling leatured. Cheshire lectured.

THINGS KNOWN AND THINGS UNKNOWN.

EVERY bee-keeper knows, or should know, that bees have five senses—viz., sight, hearing, smell, touch, and taste; but nobody can say which of the five is the most important, which the most sensitive and which of least value. Bees, in common with many other creatures, possess all the senses and find them useful. The sense of smell in bees is extraordinarily keen and powerful. Probably all their senses are wonderfully keen. It is known, too, that bees have good memories, and can remember for days and weeks where they found food and water when they were last in weeks where they found food and water waen they were last in search of it. If food be placed in any corner within their reach they will smell it and carry it home. If any be left they will go next day for it, even if the dish containing it be removed during the night. By scent they find food, and from memory they go to the place where they find it. If one swarm obtain access to the stores of another hive all the available forces are instantly put to work to rob the hive of all its stores. Again, if the hive that is being sacked be removed and another placed on its stand the robbers come as before for plunder, and on attempting to enter they find the resistance so determined and effective that they speedily abandon the work of pillage. Being scared by the strange bees the robbers evidently call into play more senses than one, and wisely stay at home. But how the knowledge of the work of plunder being checked is conveyed from bee to bee is not known by anybody, and is surprising to thoughtful observant apiarians

Many things about queens are known, and a great many things about them are not known. It is known that queens are hatched in royal cells, that they are hatched from common eggs or the eggs that would otherwise produce working bees, that they become perfect insects in royal cells six or seven days sooner than working bees are perfected in common cells, the one being fourteen days in hatching and the other twenty-one days. It is believed that queens are differently fed in their cells from the workers, and that the difference of treatment makes them queens, alters their form and colour, increases their size, and gives them dispositions and instincts quite different from those of working bees. These things are wonderful, but nobody can fully understand them. The mystery of the transformation of a common egg into a perfect queen by feeding, and of finding food to do it in seven days' less time than a worker bee is perfected, is very great.

It is well known that queens or princesses on coming to maturity and while in their meidenhood wire at the content of the common that the content of th

and while in their maidenhood pipe at one another for three days and nights, but no one can explain the mystery and philosophy of piping. It is known, too, that queens are never fertilised in their hives, but no one can understand why it is necessary that such valuable lives should be exposed to the perils of excursions in search of mates. In such excursions many queens are lost. It is known that princesses go out on such excursions when they are a few days old, and in fine weather go out once, often more than once, every day till they are successful, or for about a fortnight. It is not well known how soon after birth or how late in life fertilisation can be effected. The first ten or twelve days of a queen's life has been considered the only time for mating with drones. When I was in Scotland last summer a bee-keeper told drones. When I was in Scotland last summer a bee-keeper told me that he had just seen a young queen go out on the fifteenth day of her age, and he expressed his fear that it was too late. I thought so too, but before I left he told me that she had been mated and the hive had sealed brood in it all proper enough. Unfertilised queens are valueless, for though they lay some eggs nothing but drones hatch from them. Queens that are properly or timely fartilised produce both workers and drones.

nothing but drobes hatch from them. Queens that are properly or timely fertilised produce both workers and drones.

During the last fifty years we have known many queens live four years and die, but we have never known a fertilised queen become a mere drone-breeder before death. How little is known of the pageantry of the bees when a queen is born amongst them I How little of her superabundant fertility and of her superannua-How lettle or her superabundant fertility and of he that queens are fed from the stomachs of working bees; that the food is half digested by the bees and then given to their queen. What a marvel this is in the economy of a bee hive!

What a marvel this is in the economy of a bee hive!
Admitting that a fertile queen lays 2000 eggs a day, who can tell when she finds time for aleeping, or whether she sleeps at all or not? Again, "regicidal knots" are common and well known, but who can explain their philosophy? Two swarms each with a queen may be cast together. Presently both queens may be found in the centres of hard balls of bees, so hard and well pressed together that they could be rolled on a table like a cricket ball. Every bee seems bent on squeezing the queen to death, and yet I have known queens remain imprisoned in these hard halls of bees for many honry uninjured and at last liberated and balls of bees for many hours uninjured, and at last liberated and saved by the hand of the bee-master. On every point of bee history some things are known and some unknown. Everywhere there is ample room for future research and deeper investigation. -A. Pettigrew.

OUR LETTER BOX.

FOOD ENOUGH FOR WINTER (J. G.).—Your hives which weighed 30 he, each, independent of skeps and boards, on the 3rd of September have food enough to keep large swarms till the end of March. The swarm hived in June has lost its queen, probably by reason of age, and has reared young ones which you have heard piping. As most of the drones are now destroyed you have some reason to fear that the piping queen may remain unfertilised and be useless. In about a fortnight you may find broad in the combs, which will enable you to ascertain whether the queen is fertilised or not. If she is a drone-breeder destroy her at once and units the bees to another stock, or otherwise procure from another hive a queen for your strong stock.

WAX MOTH IN HIVE (L. L. R.).—The box arriving without the larve, all of which had no doubt escaped through the crannies, we can only report spoa the webby trails remaining. These are widently the work of the wax moths, Galleria mellonella or Achroia grisella. The insects had already established themselves in the combs of the skep before the transfer, which operation so stimulated the bees that they set their house in order, and tore out the trails and ejected the larve, dropping them on the floorboard where you found them. If the combs be examined they will be found in pisces to be undergoing repairs at the spots from which the destructive peak have been removed. No especial cleansing of the hive is necessary beyond simply sweping away the debris and all grubs. We shall be pleased to receive an account of your bees. The hive will, we think, continue to improve yet, but you must be guided by weather, about which even prophets this season had better be dumb.

REWARKS.

10th.—Fine pleasant day; bright starlight night.
11th.—Dull morning, generally cloudy throughout the day, only little smanine at intervals; high wind; calm at night.
12th.—Very damp gloomy day; heavy rain 3.30 P.M.; damp eloudy evaning.
12th.—Dull morning, rain commenced 3 P.M., very heavy rain from 4 to 4
P.M., dark and thick at 5 P.M.; wet evening.
14th.—Dull in early morning, followed by a very clear bright day; bright starlight night.

Starlight in Garly morning; very fine warm bright day; star-Thick white fog in early morning; very fine warm bright day; star-

light night.

18th.—Fine day but dull evening, with a slight sprinkle of rain.

18th.—Fine day but dull evening with a slight sprinkle of rain.

All the thermometric means are below those of last weak except the minima, which are about half a degree higher; atmospheric pressure rains. greater than last week .- G. J. SYMONS.

COVENT GARDEN MARKET.—SEPTEMBER 17.

WE are now receiving good supplies of Plums, both home and foreign produce, and prices have been considerably reduced. Large consignments of Grapes still reach us from the Channel Islands, meeting with a resty sale. Trade quiet. FRUIT.

From observations taken near London during forty-three years, the average day temperature of the week is 65.1°; and its night temperature 43.9°.

NOTES ON PEAS IN 1879.

LTHOUGH it is generally admitted that the unprosperous season which is fast drawing to an end has been the worst for outdoor gardening anyone can remember, I think so far as the Pea crop is concerned it has been in no way inferior to that of more favourable years. In some respects, however, it has been different and very peculiar. Early Peas were very late and long in showing bloom, and

the pods were extremely slow in filling or becoming fit for use, but the length of time they continued productive when they did come in was much longer than ever we experienced. Those rows from which we gathered in June were still bearing plenty of fine green pods in August. This fact we may regard as one of the advantages of such a season as this, as in hot weather Peas often come in and are over without giving what might be termed a succession of gatherings. This is especially the case in light soils, as I have no doubt many will have experienced. Mildew was also much checked during the season. I find, however, some varieties much more subject to this malady than others. Some with us now are quite free from mildew, while others in the same quarter are badly affected.

Peas sown last autumn were not a great success this spring. On November 18th we sowed Dickson's First and Best and Culverwell's Telegraph on a south border. The first named perished with the severe winter as soon as the growths came above ground; Telegraph remained strong and healthy during the whole winter, and in June we had such Peas from it as we never had before in that month, but they were not ready so early as William I. sown on a south-west border about the middle of February. This I consider the best early Pea, and is well worth extensive cultivation. Next to this Dickson's First and Best came in very well; it was also sown in February. Excepting one early Pea to come in quickly we do not think any of the second-class varieties worth growing to form a succession; but every means should be tried to get some of the fine new sorts in for this purpose. Those I chiefly refer to new sorts in for this purpose. are Carter's Telephone and Challenger, and Culverwell's Telegraph. Those who grow William I. as an early sort and these three to follow, say from the middle of June until the middle of September, will secure such Peas as no one ever thought of possessing a few years ago. To have any of the three in use by the middle of June seed ought to be sown during the first week in February in rich soil in a favourable position. Other sowings should be made fortnightly until about the beginning of June. Then the question comes, Which are the best Peas to sow to come in for use towards the end of September and during October? Many would recommend Dr. Maclean, Omega, Champion of England, Ne Plus Ultra, or some of the early varieties, but after trying all of them we have found none of them to equal two new varieties which are sure to take a high place amongst Peas, especially late ones, when they become known: their names are Richard Gilbert and Laxton's

No. 965.—Vol. XXXVII., New Series.

Sturdy, the leading characters of both being no mildew at this season of the year, and a flavour surpassing the late varieties just named. Their flavour when raw pleases everybody, and when cooked they are delicious. Richard Gilbert is larger in the pod and pea than Sturdy, and it appears more robust in growth, and in flavour it is superior to Mr. Gilbert's other new Pea Hobart Pasha. This variety produces very handsome well-filled pods, and although not so good as the variety I have just named it is certainly superior to many sorts generally cultivated as main crop Peas. Before leaving Sturdy I may say that in flavour it surpasses all other varieties of Mr. Laxton's Peas we have grown, and we have tried the most of them. Dr. Maclean and Carter's Little Wonder are two Peas which have never pleased us, as the pods fill so unevenly under the same culture as others succeed with. For a large-podded variety we have grown none to surpass Laxton's Superlative, and if it only filled as well as Fillbasket it would be most valuable, but the large pods are seldom to be found more than half filled

Veitch's Criterion, introduced last year, is an excellent Pea to produce well-filled pods with six and seven peas in each, but with us it does not boil quite so tender or sweet as some others. Amongst other varieties Maclean's Best of All, Laxton's Standard, Sharp's Invincible, Commander-in-Chief, Ne Plus Ultra, Duke and Duchess of Edinburgh, Nelson's Vanguard, and several others have not succeeded so well as we could wish this year.

Our Pea seed is annually sown thinner and thinner, and we find this plan answer better and better; in fact when the drills are opened about 1 foot in width with a spade, and the seeds put down singly all over about 3 inches apart, we find the pods as numerous and of finer quality than when the seed is sown so thick that the young plants come up in a mass. In sowing seed in autumn or early in spring it is safest to sow it pretty closely if snails or other pests are likely to be troublesome, but when these can be warded off thin sowing is the plan to adopt, as the plants come up more strong and healthy when clear of each other, and are therefore better able to withstand severities of weather. In light poor soils all Peas should have a liberal quantity of manure to feed on, but when the soil is rich an addition of manure to it is liable to force them more into leaf than fruit

I am of opinion all Peas sown in autumn should have a poorish soil, as the hardier they can be made to grow the better, and stimulants in the shape of liquid manures can always be applied at the proper time in spring.

I would advise all who have the chance to try a few varieties of Peas annually by way of testing their merits; they will find it an interesting occupation, and not at all the unprofitable undertaking which some are inclined to think it. In these days of bewildering variety of vegetables knowing what to avoid is of as much importance as what to grow, and the practical solution of these problems not only prevents much disappointment in many instances, but is a great gain in saving ground and labour from cultivating worthless or inferior crops and securing superior produce. Some think and even assert that the "good old varieties" of many vegetables are yet unsurpassed. In

No. 1617.-- VOL. LXIL, OLD SERIES.

very exceptional cases this may be so, but as a rule that theory will not bear the test of experience, and if there is one thing more than another to which this remark applies I think it is Peas.—I. MUIR.

ROSES IN TOWNS.

I THOROUGHLY agree with "BICEPS" as to the difficulty of growing the Rose in smoky situations, and I am of opinion that anyone who succeeds in growing the queen of flowers well here accomplishes a far greater feat than our more favoured brethren in the south. Considering the long and severe winter, my losses have even been less than in some milder ones; and my experience on this point seems to have been different from that of the Rev. C. P. Peach, which is all the more surprising, as the snow and frost came on before I had an opportunity of mulching the beds with manure. I agree with the few Roses you recommended to "A BEGINNER," and with "BICEPS" I can recommend Marquise de Castellane, which grows well here. "BICEPS" is suspicious of Charles Lefebvre. It grows and blooms well here, but its duplicate, Marguerite Brassac, does even better, being the more vigorous grower, but the flowers are alike. La France on the seedling Briar and Madame Victor Verdier do well here, and John Hopper is the freest I have and does not blight. The remarks of "BICEPS" as to Général Jacqueminot I am surprised with, as it is everybody's Rose, here doing splendidly in almost any situation.

The following do well here—Abel Carrière, Abel Grand, Annie Wood, Auguste Rigotard, Beauty of Waltham, Bessie Johnson, Boule de Niege, Charles Lefebvre, Capitaine Christy, and Marie Baumann on seedling Briar; Comtesse de Serenye, Camille Bernardin, Dr. Andry, Duke of Edinburgh, Duchesse de Vallombrosa, Dupuy Jamain, Edouard Morren, Ferdinand de Lesseps, Fisher Holmes, Jean Liabaud, Jules Margottin, Lord Macaulay, J. Stuart Mill, Baronne de Rothschild, Madame C. Joigneaux, Madame Nachury, Madame Lacharme, Mülle. Eugénie Verdier, Maréchal Vaillant, Magna Charta, Etienne Levet, Paul Neyron, Pierre Notting, Prince Camille de Rohan, Princess Beatrice, Princess Mary of Cambridge, Reynolds Hole, Sénateur Vaisse, Sir Garnet Wolseley, Victor Verdier, and Miss Hassard. Gloire de Dijon and Souvenir de Malmaison also grow well and bloom splendidly. Of the former Rose I only end the shoots, but cut out the weak ones, and find this treatment to suit it. The season here has been a very unfavourable one—so much wet, but I have had finer individual blooms than I ever had, the dark Roses being the best. The light blooms rotted off with the wet

blooms rotted off with the wet.

To "A BEGINNER" "BICEPS" recommends liquid manure. I should judge that he lives either in a town or very near. Doubtless if this is so, manure being scarce and the soil light, liquid manure will be a benefit. I live about four miles out of the town, my garden being unprotected, with a strong loamy soil and clay bottom. I do not use any liquid for plants in the open ground, finding that it brought much mildew. In this I am fortified by the opinion of the Rev. C. P. Peach (see "Rosarians' Year-Book" for 1879). My treatment is to mulch hearly in winter with stable manure and fork it well in in the spring, pruning the trees in March or beginning of April. For a summer dressing I adopt the treatment recommended by Mr. Rivers, mixing dust from a malt kiln with stable manure minus straw, in equal quantities, letting it stand for a day or two, watering a few times with liquid manure, and then using it as a top-dressing in, say, April and May, and it soon tells a tale. This mixture must not ferment, as the smell is something horrid.

My plants are mostly dwarfs on the Manetti. "BICEPS" says the lives of town Roses are short, but I have found that they last much longer by taking them up and replanting in two or three years' time. Some of mine that I moved last autumn I found had made good roots above the stock, so I cut the stock away, and they have done better than ever this season. I join with "BICEPS" in thanking "WYLD SAVAGE," Canon Hole, "D., Deal," Rev. C. P. Peach, and others for their interesting articles from time to time in your valuable Journal; but living as we do in a less genial climate our experience does not always correspond with theirs. Being a non-exhibitor and only growing the Rose for the love of the flower, although a lover and attender of Rose shows, I often sigh as I look at the gems at the great shows and think I should like to grow similar blooms, but found to my cost on trying, that some of the choicest sorts are not suited to these smoky districts, so have to fall back on the vigorous growers. Sultan of Zanzibar and Reynolds Hole

are quite distinct with me, but the latter is more suitable, being the better grower. The Sultan blooms well, but has hardly grown at all this season. I look with interest for the election of garden Roses.

In answering "BICEPS" my wish has been to encourage the growing of the Rose near large towns, as one sees them planted and then left to shift for themselves, and consequently they die off in a year or two, then people say they will not grow with them. The same people on seeing the Rose garden of one who has a pride in trying to grow them well say, "Ah! you have a different soil to mine," when, as a rule, it is the neglect rather than the difference in soil and situation. If this is of interest I shall be glad to answer the remarks of those who live in similar districts, but will promise to keep clear of giants and "WYLD SAVAGE."—F. W. J., Bradford.

AUTUMN ORNAMENTS.

THE following plants are highly attractive in the autumn, and should be grown in all villa gardens if suitable positions can be found for them.

CLEMATIS JACKMANNI.—This is well known now, and is deservedly popular. Its purple flowers are for several weeks at this season of the year extremely bright and abundant. The flowers frequently measure 6 inches in diameter, and when produced in masses against walls, over porches of houses and cottages, are easily distinguishable some hundreds of yards distant. It is also very attractive when planted on rootwork and allowed to ramble over it, also when grown in beds and trained regularly around stout pyramidal wire trellis. Sometimes this variety, with others, are trained along chains, forming beautiful festoons. To ensure a good effect the first season it is of the greatest importance that strong established plants be procured during the winter months, and planted out in ground to which some well-decayed manure and leaf soil has been added; plant them about the middle or end of March, at which time they may be expected to escape any check from late spring frost. Timely attention to training is all that is required afterwards. The following spring the plants should be cut hard back, the soil around loosened with a fork and mulched with manure, and as the young robust growths are produced regulate them as before.

HYDRANGEA PANICULATA GRANDIFLORA.—At the present time this plant is in its fullest beauty, and from its hardiness and the freedom with which its massive clusters of pinkishwhite flowers are produced it is worthy of being classed amongst one of the best of deciduous hardy flowering shrubs. As a low-growing shrub in a mixed border we have nothing at this season of the year to equal it, for its flowers remain in beauty a very long time. When not in flower its habit and strength of its wood have not much to recommend it. We received two of these plants from a nursery in the autumn of 1877, and so weak-looking were they that we despaired of having any bloom for a few years, but the following autumn every growth produced a truss of bloom. Since then one plant has been unfortunately killed, but the other has flowered again most profusely and is now very fine. As the trusses of bloom are too heavy for the slender wood we have staked every flower truss, which displays them to the best advantage.

HYPERICUM OBLONGIFOLIUM.—This is a very attractive shrubby species with beautiful showy bright golden waxy flowers that when seen at a distance may be mistaken for small yellow Roses. It is free-flowering, and very showy at a time when most other flowering shrubs can only lend their foliage to add to the effect and beauty of a garden. This species with a few others merit a little more popularity than they have yet obtained.—J. W. MOORMAN.

STOPPING AND TRAINING TOMATOES.

DIRECTING Tomatoes to be stopped as are Cucumbers is liable to mislead. All secondary shoots from Tomatoes show bloom when they have made four or five leaves. The stopping should be done a leaf or two beyond the bloom, and besides as soon as the framework of the plant is formed every shoot from the axil of the leaves should be taken out as soon as it can be get hold of. The latter point not being clearly insisted on is where the directions sometimes given are imperfect. It should be done whether the half dozen bunches the plant is allowed to bear are upon short laterals from an upright stem, which is the best method for walls, or upon the branches of a fork, produced by stopping the plants when they have three or four

leaves, which is the best way of growing them to sticks in the open ground. In the latter way the two limbs of the fork must, of course, be allowed to extend themselves after bearing their first blooms till three of the latter are upon each shoot. Then these shoots are to be stopped a leaf beyond the last bunch, and all axillary ones from them carefully eradicated as they come.

In this neighbourhood Tomatoes in the open air, however skilfully trained against a south wall, are likely to prove a failure. They have only set a few of their blooms.—A. BOYLE,

Pembrokeshire.

FRENCH NOTES.—No. 2. FONTAINEBLEAU.

SELDOM have I paid a visit that more saddened me than that which I recently paid to my good old friend M. Souchet at Fontainebleau. It is now upwards of twenty years since, impelled by a desire to know the man who had elevated the Gladiolus into the rank of a florists' flower and had done so much to enrich our English gardens in autumn, I ventured to call upon him at Fontainebleau. I had no introduction, nor did I need any. All who have ever been brought into contact with him will readily believe that, for a man more full of real kindliness, more amiable and thoughtful for others, could not possibly be. We became friends, and never but once since then when I have visited France have I failed to pay him a visit. His amiable and excellent wife, too, was ever ready to welcome me. He was at my first visit the jardinier-en-chef at the Château, but some few years afterwards he retired to the beautiful new house he now occupies. About forty years ago he was attacked by a malady of the skin, which has resisted all remedies, and has gradually overpowered what must have been naturally a strong constitution. He is now a complete wreck, can hardly move about, and has to be lifted up by means of an ascensoir; but in heart and spirit he is still the same kindly loveable man that he ever was. His horticultural establishment has passed into the hands of Messrs. Soulliard and Brunelot. He himself takes an interest in seeing the improvement each year makes in his favourite flower, and during the season his rooms are decorated by Madame Souchet most artistically with it. Of these I shall have more to say presently. But there was another saddening influence in my visit, and that was the condition of the Forest itself. It is not too much to say that those who recollect it in its glory will not see it again for many years as it used to be. I read some time ago in an article in the "Revue des Deux Mondes" of the destruction caused by what is called in France "verglas," and which we should designate as frozen rain, but I had no conception that it was anything like what it is. It appears that there had been a heavy fall of snow with which the trees were laden; a thaw set in, but suddenly it turned to rain with a cold wind, and the rain as it fell froze. Thus the trees became weighted, not with snow, but with ice of some inches thick. The consequence was, that becoming brittle under the influence of the frost, they snapped and broke in all directions. Where, in the fork of the branches the deposit had been the greatest, there the destruction was most certain. All of the trees suffered, but more especially the Firs and Birch, as far at least as I could see. Had I been told that the German troops had been practising with cannon to see what destruction they could effect I should not have been surprised, for it was just as if a large shot had hit the tree and scattered the branches in all directions. You might see acre after acre cleared as completely as if the fellers had been at work, and I was told that it would take twelve years to clear away the débris. The streets of the town were in such a condition that skaters could go from one end of it to the other.

The lateness of the season did me at least one kindnessenabled me to see the Gladioli of Messrs. Soulliard & Brunelot in their full beauty, and a great treat it was; for while the main collection of the older varieties are grown at Montereux, the newer ones and the seedlings are grown at Fontainebleau; so that I had the opportunity, not merely of seeing those in commerce, but also those which they purpose sending out next year. There was thus an opportunity of comparing them, and also of seeing some of those which were just showing their first bloom, destined to be the favourites perhaps in coming years. I had also much conversation with the raisers on the varieties sent out, and on what seemed to me a difference between the English and French taste in this matter; for although flowers such as Horace Vernet, Murillo, Camille, Meyerbeer, and others which come up to our notions are considered as good, there are others which were pointed out to me as good which we should not class as such. Again, I saw varieties which I have never been able to see in good form at home which were simply beautiful, a difference probably in soil and climate effecting this. I could find, too, traces, although only in a slight degree, of the malady from which we suffer so much here, but there it unquestionably was. It may be, and probably is, aggravated by the lower temperature and moister atmosphere of our autumns, but that it there exists there can be no doubt. My friends were very much astonished when I told them of my great losses, but said they knew something of it, and attributed it to some malady which was more injurious in some sorts than others.

Amongst the varieties of the past season which struck me as particularly good, but which I fear, owing to the lateness of the season, I shall not be able to see in my own garden, are the following:-African, a very remarkable dark flower; I think perhaps the darkest yet raised. The ground is scarlet, but flushed with a deep brownish crimson, the effect of which is heightened by a large white spot in the centre of the flower. The spike is a well-formed one, and the flowers are closely packed together. Hesperide, a large and well-formed spike; the flowers white heavily flaked with salmon rose. Ovide, a very long spike of carmine red flowers, with a white line on each petal and large white spot in centre of the flowers. Pygmalion, long spike of large flowers, cerise red flamed with deeper red; pure white spots edged with violet. Esmeralds, a remarkably coloured flower, French white ground edged and striped with rose, with large citron yellow blotches in the centre of the lower petals; a very distinct variety. Many of older flowers, such as Psyche, Leda, Murillo, De Michel, were in great beauty, and altogether the treat was one I am not likely to forget.

The Gladiolus is not the only flower which is being improved by our friends at Fontainebleau. They have taken the Amaryllis in hand, and an immense quantity of seedlings had bloomed in the open air. They are of the vittata race, and are consequently nearly hardy in that part of France. They are consequently nearly hardy in that part of France. are simply cultivated like any other hardy bulb, are left in the ground all the winter, and only slightly covered with leaves. They are of two distinct characters, one having pure whiteground, the other red, and are marked and ribboned with white, red, salmon, purple, &c., and when blooming they must be a grand sight. Of course at this season they were all over. They would succeed with us under ordinary greenhouse treatment, and to those who cannot give heat they ought to be a boon. Those who can would probably prefer the more showy formosissimum race, but to amateurs of small means and space they would seem to afford a fresh field of enjoyment.

We are constantly complaining of our climate, and this year we have some good reason to speak of it as bad, but when comparisons are instituted between it and that of the north of France it is as well to be remembered that there is a slight mistake on the point. I do not believe that until you get to Paris there is much difference. The corn was in about the same state of unforwardness that it was about my own home when Lieft it, and the fruit crops as poor as with us. The famous Mon-trieul Peaches had not the flavour of former years, and even at Fontainebleau where so many of the Chasselas Grapes are grown, and from whence they are supplied in large quantities both to the Paris market and foreign countries, it was very much. doubted whether many of them would ripen this year. Even at Thomery, where they are grown in greater abundance still, the same complaint was made. "I should not," said M. Soulliard, "like you to say that you left Fontainebleau in the middle of September and were not able to taste our Grapes; and so out of some very sheltered nook he managed to get me a small bunch; it was, however, hardly ripe. I mention these little matters to reconcile ourselves to the most uncanny year that one has probably ever passed through.—D., Deal.

CLETHRA ARBOREA.

I AM very glad to see that this rare old plant is being taken a little notice of, for it is an excellent evergreen greenhouse shrub, and is one of the very few that will stand rough treatment and yet give satisfactory results. A few years ago a plant of it, probably twenty years old, was under my charge for over three years; it was in a 12-inch pot and had been so for a long time, and was still in the same pot when I left. Want of room prevented this and many other plants from

being potted on or shifted into tubs; but Clethra arborea, | years ago, and there is a marked variation in the plants both although not annually potted, or even watered with any stimulants, never failed to keep its foliage green and always flowered freely every year. It was placed outdoors during the latter part of the summer and housed in October. was watered freely when making its young growth, and was wintered in a cool airy greenhouse principally with Australian plants. Its height was about 9 feet; the flowers were sweet and very useful for cutting, and the engraving of it in the Journal a few weeks ago was a very good representation of it .- H., Peterborough.

PEACHES AND NECTARINES IN DORSET.

OF these fruits I have had an excellent lot under glass of fair size, specially of Early Louise, the best very early Peach; Barrington, Early Alfred, Royal George, and Grosse Mignonne. Out of doors I have a very satisfactory crop as regards numbers, but they swell slowly. The Princess of Wales, Dr. Hogg, Early York, Nectarine Peach, Early Ascot, a fine colour; Noblesse, Royal George, Golden Frogmore and Bellegarde, and Rivers's Orange and Elruge Nectarines are to the fore. At one time I despaired of their ripening, but since we had a little sun they progress, but I hardly think they will be their usual size; if they ripen not I shall have them preserved whole. The wood for next year is very good.—W. F. RAD-CLYFFE, Okeford Fitzpaine.

TWELVE HARDY HERBACEOUS PLANTS OF THE MONTH-SEPTEMBER

HERBACEOUS borders in the present month are not in general the most attractive portions of the flower garden, yet there should still be plenty of bloom in good collections. Extreme neatness is now needed to render the borders enjoy-

able, and autumn propagation by division may still be carried on. The following are some of the best.

Listris spicata (the Long-spiked Liatris).—A handsome erect-growing Composite with stiff flower stems 2 to 3 feet high, clothed with linear leaves, and bearing spikes 10 inches long of light purple flowers. From each floret long filaments of a lighter colour are projected, and the flowers open in succession from the top of the spike downwards. Increased by division of the tuberous corm-like roots. This plant is a native of North America, where it is known as the Button Snake-root.

Sedum spectabile (the Showy Sedum).—This is the very best of the Orpine section of Sedums, and is well known as a fine autumn-flowering plant. The flowers are in large corymbs, sometimes as much as 6 to 8 inches across, and are a light rosy purple. In open sunny situations the plant seldom grows more than a foot or 15 inches high, and it is admirably adapted for growing in beds or borders, or for pot cultivation. are several varieties with lighter or darker shades of purple, and one with faintly variegated leaves. Propagated by seed, division, or cuttings. Native of Japan, and better known as 5. Fabaria.

Anemone japonica rar. Honorine Jobert (the White Japanese Anemone).—A continental variety of the Japanese Anemone, having pure white flowers 2 inches across with yellow stamens. It grows 3 feet high, and has large, downy, Vine-like leaves. Propagated by cuttings of the creeping underground shoots or by suckers, which are plentifully produced when once the plant is established.

Tritoma Uvaria (the Poker Plant, or Torch Flower).—This noble Lilywort is too well known to need description, being one of our most valuable autumn flowers. Of a number of varieties grown, that known as glaucescens seems to be the best, producing enormous spikes of tubular flowers, vermilion shading into crange-yellow. Can be propagated by seed, but the seedlings frequently come inferior to the type. Division in spring is preferable, or if divided in autumn the plants should be wintered under glass. Succeeds best in deep rich soil, which should be liberally manured. Native of the Cape of Good Hope.

Sida mairæfora (the Mallow-flowered Sida).-This tall Mallow is not usually accounted a choice plant, its habit being long and leggy, but the beautiful rose-coloured flowers, often 3 inches across, are invaluable for cutting late in autumn.
Only suitable for the back lines of large borders or among shrubs. Propagated by seed or cuttings. My stock of plants was raised from a packet of seed had from Mr. Ware some

as regards size and colour of flowers, from which I infer that it is a plant capable of being improved by crossing. A native of Mexico.

Galatella hyssopifolia (the Hyssop-leaved Galatella).-A pretty Starwort, bearing corymbs of pale purple narrow-petalled flowers with yellow discs. It grows about 18 inches high, and has slender stems clothed with narrow pointed leaves. The flowers form a loose corymb, and appearing as as they do in succession the period of bloom is more prolonged than in most of the Asters, to which it is nearly related. Increased by division. Native of North America.

Helenium atropurpureum (the Dark Purple Helenium) .-This handsome Composite, not often seen in collections, grows 2 to 3 feet high, and bears numerous large flowers of various shades of purple and which are slightly fragrant. Though impatient of heavy clay it is quite hardy in rich light soils. Native of Texas.

Chrysocoma Lynosyris (Goldylocks). - One of our mres natives, but yet a pretty flowering border plant. It throws up many small wiry stems thickly covered with narrow leaves, bearing corymbs of yellow button-like flowers. This pecies seldom grows over 2 feet high, and is increased by

division in spring.

Aster nori-belgii (the New York Starwort).—This is one of the best of a very numerous family, which includes many species not worth growing. The flower stems rise 3 or 4 feet, bearing in open racemes numerous light blue flowers. Native of North America.

Saponaria officinalis fl. pl. (the Double-flowered Soapwort). —The single Scapwort is a not uncommon native plant, and is the only representative of the genus in Britain. The double form grows about 2 feet high, and its flowers are a very light pink or flesh colour, not unlike small blooms of some of the Tree Carnations. The plant throws out numerous underground shoots, and in this way propagates itself to an extent some-times not desirable. A variety of the single form with yellow

variegated leaves is well worth growing.

Lobelia syphilitica (the Tail Blue Lobelia).—The genus Lobelia gives us some splendid herbaceous plants, but as in these notes I have avoided quoting any that require the protection of glass during winter, this is the only species admissible. Having grown it for many years without losing a single plant from frost, whilst L. fulgens and cardinalis left out have been destroyed, I can answer for its hardiness. It, however, falls far short of these species as an ornamental plant. It grows about 2 feet high, bearing leafy spikes of light blue flowers, passing to white on the lips of the corolla. Propagated by seed or by removing the offsets in autumn. Native of Virginia.

Hypericum olympicum (the Olympian St. John's Wort).-This is a neat symmetrical plant, forming compact bushes 15 to 20 inches high. The stems are slender and woody, covered with smooth pointed leaves, and bearing numerous bright yellow flowers, each nearly 2 inches across. In some catalogues it is said to be a recent introduction, but it appears to have been known in this country in the early part of last century. Increased by cuttings. Native of Greece and the Levant.—R. D. TAYLOR.

FORCING STRAWBERRIES.

"FORCER" is certainly astray in his idea of the points under discussion—viz., layering the runners into the fruiting pots versus divesting them from the parent plant, potting in 3-inch pots, and drawing up weakly in close frames. Many besides myself are ignorant of the disadvantages "FORCER" would have us believe are connected with placing the runner first of all in the pot it is intended to fruit in. Our ideas are that the plan we condemn might amuse some who have abundance of labour at command, and can afford time to carry out the severing and close-frame system of cultivating Strawberries. still say a system that economises labour has a decided and great advantage, especially so when the produce is equal, or in many cases superior, to that of other systems. The practice of layering into fruiting pots is not east on one side so much as "FORCER" concludes it is, but is each year being more largely practised. Layering into the fruiting pots is largely practiced. in Lancashire and by the majority of good growers round Liverpool. Those who once fairly adopt the system are alow in discarding it for others. We are extremely obliged to "FORCER" for his reference to

Mr. Thomson's valuable work. We have no special desire to discuss any of the points the author of "Fruit Culture under Glass" has decided upon for the guidance and instruction of those who seek knowledge from that excellent work. It would be well for many gardeners to test for themselves the advantages and disadvantages of a system before condemning it. The most remarkable thing in "FORCER'S" letter is that he points to the plants of Mr. Thomson and the produce of those plants, and in his own words "bester he never saw," and then goes on to describe his system of preparing the plants. Why does he not follow the advantageous system he points out and tell us of his own practice?—W. BARDNEY.

NEWCASTLE HORTICULTURAL AND BOTANICAL SOCIETY .- SEPTEMBER 17TH AND 18TH

THE above Society have held their third Show for this year. To each of these Shows it is the object of the directorate to give a distinctive character—the spring Show for Hyacinths and other flowering plants, the summer Exhibition for plants in general, and the autumn for fruit and florists' flowers. This Show was held on Wednesday and Thursday last in the Town Hall and Corn Exchange. It is a pity that the Society have not a larger place for their purpose, for the space, large as it is, is decidedly too small for the dimensions to which the Show has attained, and the productions of many nurserymen who wished to send plants for exhibition and embellishment could not be accepted.

The Show was a very large and excellent one, indeed it was declared by many competent authorities present to have been the best fruit and florists' flower show that has been seen in England this year. In many places cultivators have failed to produce Hollyhocks or Gladioli in exhibition form this season, but at Newcastle those flowers were thoroughly represented, and although they were not equal to those generally shown in the north yet

they were considered extraordinary for the season.

The fruit was a great improvement on last year, especially the Grapes, which were the admiration of all who saw them, and the Grapes, which were the Bulliamond of Bridge and con-in some of the classes there were ten and fifteen entries, and con-consistive many availant dishes received no awards. Peaches, sequently many excellent dishes received no awards. sequently many excellent dishes received no awards. reaches, Nectarines, and other hardy fruits were also good, but most of the examples had probably been grown in orchard houses. The epergnes and table decorations, which always form an important feature of the autumn exhibition, were both numerous and good. The table decorations were on the centre table in the Corn Exchange, which extended the entire length of the hall, and betwitt each competitor's table were placed two sets of table plants; this assisted to define the tables, which was very convenient to visitors. On both sides of the central table were the tables with the fruit and florists' flowers, and on looking down on the Exhibition from the staircase leading to the Town Hall the effect was very fine. We are glad to record that two Judges were provided for each section of the Show. We have previously pointed out the necessity of this, as the magnitude of the Exhibition renders it almost impossible for one man to adjudicate satisfactorily in so many classes. On this occasion the awards appeared to give general satisfaction.

occasion the awards appeared to give general satisfaction. The Committee are still as assiduous as ever in their endeavours to still further raise the standard of their exhibitions, and we have no doubt they will succeed. We will now refer to the classes, commencing with the FRUIT.—For eight dishes of fruit there were six competitors. Mr. Laidlaw, gardener to the Bev. J. Burdon, Castle Eden, receiving the premier award with a very fair Smooth-leaved Cayenne Pine, very fine Black Hamburgh and Buckland Sweetwater Grapes, Violette Hâtive Peaches, Elruge Nectarines, Figs, Goliath and Jefferson's Plums, and a moderate Melos. Mr. Westcott and Mr. Ingram, gardeners to the Dukes of Cleveland and Northumberland, of Baby and Alnwick Castles, were placed equal second: Mr. of Raby and Alnwick Castles, were placed equal second; Mr. Westcott showed a Smooth-leaved Cayenne Pine, rather small; magnificent Black Hamburgh Grapes, perfect in every respect; and Waltham Cross, a very rich amber, and very compact; splendid Boyal George Peaches, well-coloured Pitmaston Orange Nectarines, very large Moor Park Apricots, and Golden Gem Melon. tarmes, very large Moor Park Apricots, and Golden Gem Melon. This was quite equal to the premier collection. Mr. Ingram's best dishes were excellent Black Hamburgh and Muscat of Alexandria Grapes, a very fine Smooth-leaved Cayenne Pine, Violette Hâtive Peaches, and Pitmaston Orange Nectarines. Mr. Jowsey, gardener to G. Gilpin Brown, Esq. of Sedbury Park, was third; his Muscat of Alexandria and Black Hamburgh Grapes were very good, also were the Peaches and Nectarines. All the collections were highly meritorious. For six dishes of hardy fruit, which were, generally speaking, fine, Mr. Westcott was first with Goliath Plums, Morello Cherries, White Juneating Apples, Semper Fidelis Raspberries, exceptionally large and fine; Talfourd Gooseberries, and the Raby Castle Currant. Mr. Ingram was second, and Mr. Mann, gardener to Mrs. Hornsby, St. Vincent's, Grantham, third. In these collections the notable dishes were May Duke Cherries, Gloria Mundi Apples, and Golden Drop Plums.

Grapes.—In the class for six bunches of Grapes, not less than

ree varieties, ten execuient lots were staged, all possessing co siderable merit. Mr. A. Kirk, gardener to Mrs. McFie, Erner Caetle Douglas,was first with superior examples, both bun-Castle Douglas, was first with superior examples, both busehes and berries being fine and possessing high colour and finish. The varieties were Black Hamburgh, Buckland Sweetwater, and a marvellous bunch of Black Alicante. The bunches averaged about 4 lbs. each. Mr. Kirk is unquestionably a thorough Grape-grower and has had great success in Scotland, and yet, to his credit be it said, he has only one vinery 30 feet long. Mr. Jowsey, gardener to G. Gilpin Brown, Esq., Sedbury Park, Richmend, was an excellent second, and possessed more varieties than Mr. Kirk. His bunches were exceedingly fine of Muscat of Alexandria, Black Hamburgh, Treeblano, and two fine bunches of Black Alicante. Mr. Westcott was third with Black Hamburgh, Muscat of Alexandria, fine but rather small in bunch; Mrs. Pearson, and Golden Champion without a spot, and a very fine bunch of Gros Colman, extraordinary in berry but scarcely ripe. Mr. Witherspoon of the Red Rose Vineries, Chester-le-Street, ran him closely, but his bunches were scarcely ripe although fine in other respects.

For two bunches of Black Hamburgh no less than seventeem lots were staged, Mr. Hanson, Grey Towers, Northallerton, being

lots were staged, Mr. Hanson, Grey Towers, Northallerton, being first with fine examples beautifully coloured, about 2 to 8 Ba. mest with the examples scattarily coloured, about 2 to 8 me, weight. Mr. Westoott was second, his bunches being good but smaller than the first. Mr. Laidlaw and Mr. Stainthorpe, Ownesby Gardens, Middlesborough, received equal thirds. An excellent class. For two banches of Black Alicante, Mr. Hammond, gardener to Sir Wilfrid Lawson, Brayton Manor, Carlisle, was first with superior produce; Messrs. Ingram and Hanson following next with larger but not such well coloured bunches. For two black bunches of any other kind, Mr. D. P. Bell, Clive House, Alnwick, was first with Alnwick Seedling of magnificent appearance. They were splendid bunches, and the berries were of great size and fine were spiencial bunches, and the betries were or great size and line colour, and elicited general admiration. Mr. Ingram was second with two remarkably fine bunches of Mrs. Pince 2 to 8 hs. weight; Mr. Jowsey following with very good bunches of Barbarossa. For two bunches of Muscat of Alexandria nine lots were also staged, Mr. Jowsey being first with well-coloured examples; Mr. J. Aitken, Kirkleatham Hall, second; and Mr. Ingram third. For two Buckland Sweetwater Mr. A. Kirk was first with fine and spotless examples, Mr. Laidlaw had the third position. For two bunches of any other white Grape Mr. A. Kirk was again first bunches of any other wante orage at a summer Grape Duke of Bucolench, faultless in colour and fine in shape; Mr. Carrick and We Laidlaw following in the order named. For the heaviest Mr. Laidlaw following in the order named. For the heaviest bunch Mr. Kirk again followed up his success with a good bunch

bunch Mr. Kirk again followed up his success with a good bunch of Trebbiano about 18 inches long and the same across, weighing just 10 fbs.; Mr. Ingram was second with White Tokay, 5 fbs.

Pines and Melons.—There were only three Pine Apples. Mr. Noble, gardener to T. Fry, Esq., Woodburn, Darlington, took first with a very fine Queen between 4 and 5 fbs. weight; Mr. Laidlaw and Mr. Ingram having the remaining prizes. A dozen Melons were staged, some were very inferior. Mr. Hammond was first with a finely-netted green-flesh of good size; Mr. A. G. Brown, gardener to T. Barnes, Esq., Whitburn, second with a fine deep green-fleshed Melon named Mark Thompson; and Mr. James Thompson was third. Thompson was third.

Peaches and Nectorines.—Peaches were without exception Peaches and Nectorines.—Peaches were without exception exceedingly fine. Mr. Forsyth, gardener to George Carina, Req., Monkton Hall, Boldon, was first with Noblesse, finely coloured and very large; Mr. Hammond being second with a mixed dish, and Mr. T. Henderson third. Nectorines were also very good. Mr. Ingram was first with Pine Apple Nectarine; Mr. R. Thompson, Rose Villa, Bedlington, second with the same variety; and Mr. Elsworthy of Court Hey, Liverpool, third with Elruge. Twelve lots of Apricots were exhibited, Mr. Westcott securing an easy first with Moorpark, very large and well ripened for the porth. north.

north.

Apples, Pears, and Plums.—Many dishes were staged, but the fruit was not of superior quality: most that were ripe appeared to have been grown in orchard houses. For twelve dessert Apples in four varieties Mr. Rylance, Oughton, Ormskirk, was first with Irish Peach, Red Astrachan. Red Quarrenden, and Lord Derby. For twelve baking Apples Mr. Rylance was again first with Karl Derby, Lord Suffield, Surprise, and King of Apples. Twelve Pears in four varieties Mr. Wood, Fenham Hall, was first with Williams' Ron Chrétien Duckesse d'Angoulème Beurré Giffand and Windsor. Bon Chrêtien, Duchesse d'Angoulême, Beurré Giffard, and Windsor. Twelve dishes of Plums were exhibited, Mr. Hanson winning with Greengage. In addition to what was for competition the Rev. C. P. Peach sent for exhibition a large collection of fruit—namely, forty varieties of Apples, twenty-five of Pears, and fifteen of Plums. Some branches of the Victoria Plum were completely laden with fruit—a very interesting and valuable contribution.

TABLE DECORATIONS, as we have said before, were very extensive, and nearly all possessed considerable taste and merit. The President's prize of a ten-guinea cup was taken by his own gardener (Mr. Thompson), who was pre-eminently in the front. His table was well filled, and yet not too heavy. A Marsh stand formed the centre, with two smaller ones at the end; the top of the former was chastely filled with Water Lilies, Tacsonia insignis, the flowers drooping down; the base being done with

richer colours of Allamandas, Dipladenias, and Ixoras, all margined with Davallia Mooreana, and round the base were six small china vases. The end stands were very effective, the base of them being Water Lilies, which contrasted agreeably with the heavier shades of the base of the Marsh stand. No plants were employed. Six dishes of fruit and ten smaller glasses completed this excellent table. Mrs. Gellender, Grey Street, Newcastle, was this excellent table. Mrs. Gellender, Grey Street, Newcastle, was second. She employed very choice flowers, the base of her stands being rather heavy, and the table altogether a little crowded. Mr. Methvin, gardener to T. Lange, Esq., Heathfield House, Gateshead, was an excellent third. Table plants were good, twelve lots being staged. Mr. Methvin was first with an even lot of Geonoma gracilis, Croton Lord Derby, Cocos Weddelliana, Aralia reticulata, and Pandanus Veitchii. In one of the lots a plant of Amaranthus Henderi was shown finely coloured.

Epergnes and baskets of cut flowers were excellent both in the open and amateurs' classes. For the former Messrs. Rymer and Davidson took first; in the latter Mr. Hugill and Mr. Rymer. Hand and bridal bouquets were very good, Mr. Rutherford winning with his bridal bouquet—a chaste arrangement of Stephanotis, double Jasminum, Gardenias, Rose Niphetos, and slightly margined with Adiantum gracillimum. In this class eight bouquets

gined with Adiantum gracillimum. In this class eight bouquets were shown, and not a bad one amongst them. In the corresponding class for hand bouquets there were eleven examples

equally good, Mrs. Ramshaw winning the premier prize.

Cur Flowers.—Dahlias were a strong feature, no less than ten
twenty-fours were staged. Mr. Charles Rylance was first with twenty-fours were staged. Mr. Charles Rylance was first with fine large blooms, but not by any means coarse, as we have so frequently seen them this year. The best flowers were Clars, Alex. Cramond, The Countess, Flora Wyatt, Criterion, Royal Queen, Vice-President, John Laing, Empress Maud, Harry, Flag of Truce, Mrs. Shirley Hibberd, J. Neville Keynes, James Cocker, Louisa Neale, Constancy, G. Smith, and Aurora, all very fine. Mr. John Walker, Low Fell, Gateshead, and Mr. T. Painter, Small-wood, Cheshire, secured the remaining prizes. Mr. Walker's were fine but the blooms were rather small, the best being Louisa Neale, J. Cocker. Chris. Ridley (magnificent). Flora Wyatt. Countess of fine but the blooms were rather small, the best being Louisa Neale, J. Cocker, Chris. Ridley (magnificent), Flora Wyatt, Countess of Pembroke, Vice-President, and Thomas Goodwin, a fine dark. For twelve Fancies, distinct, there were six lots. Mr. Rylance was again first with unusually fine blooms of Summertide, Mrs. Saunders, Charles Wyatt, Fanny Sturt, Singularity, Prospero, Hercules, Queen Mab, and Gaiety, a flower of 1879; Mr. W. Shaw and Mr. T. Painter following with very good stands. Mr. Carrick and Mr. Fletcher securing premier honours for twelves and six's in the corresponding amateurs' classes. Hollyhocks were also in the ascendant, as many as six stands of twenty-four blooms being the ascendant, as many as six stands of twenty-four blooms being staged. Mr. H. Clark, Rodley, Leeds, was first with fine fresh blooms. For twelve Hollyhocks Mr. Spoor, Swalwell, was first. There were not many Boses, prizes only being offered for twelve blooms in six varieties. Messrs. Mack & Son, Catterick Bridge, were first with remarkably fresh blooms for the time of year of Madame Sophia Dumaresque, Maréchal Niel, Paul Neyron, Maurice Bernardin, Alfred Colomb, Princess Beatrice, Velours Pourpré, and Queen of Waltham; Mr. Burrell, Heighington, Darlington, was second. Both Feathered and Globe Asters were largely shown, and embraced some very choice flowers; also were Carnations and Picotees, Mr. Edward Adams, Swalwell, receiving a firstand Picotees, Mr. Edward Adams, Swalwell, receiving a first-class certificate for a seedling crimson Bizarre, a fine flower of good substance. Several noted exhibitors competed, including Messrs. Rudd, Bradford, Scott, Jeavans, &c. French and African Marigolds were fine, and shown in enormous quantities, especially

For eighteen Gladioli Mr. W. Spoor was first with extraordinary good spikes of Ninon de l'Enclos, Christopher Colomb, Velleda, Adolphe Brongniart; these were in his front row, and all had fifteen blooms well open. Then followed excellent spikes of Horace Vernet, Addison, Orphée, and Giganteus. Mr. George Charlton's second-prize stand contained excellent spikes, Shakespeare being fine and 4 inches across. There were six lots, and gave the hall a charming appearance. In the corresponding class for nine spikes, not less than six varieties, Mr. R. Harkness, Allendale, was first, his collection including a white seedling feathered with crimson, fine; Belladonna, grand, 4 inches across; Eugène Scribe, and Penelope. Pansies, cut blooms of Zonal Pelargoniums, some average Fuchsias, Liliums, and Coleuses completed this excellent exhibition. For eighteen Gladioli Mr. W. Spoor was first with extraordinary

Several collections of Tea Roses by Messrs. Mack & Son, Catterick, were sent for exhibition. A very large collection of Bronze and Tricolor Pelargoniums, embracing most of the recent Phloxes. Mr. Witherspoon received an extra prize for a tastefully arranged basket of fruit. Mr. Dobbie, florist, Rothesay, also sent a capital stand of vegetables, together with a choice collection of herbaceous flowers. He was awarded an extra prize Mesers. herbaceous flowers. He was awarded an extra prize. Messrs. Lazenby and Wardle sent good blooms of Verbenas and Carnations. Mr. W. J. Watson, nurseryman, Fenham, contributed an excellent collection of choice hardy Conifers suitable for every purpose of balcony and town decoration. The charming Cupressus alba spics, attaining a silvery appearance during the summer months, was highly attractive, as was also the Golden Cupressus Lawson-

iana lutea. Cupressus Nutkaensis is perfectly hardy, and succeeds well in the neighbourhood of Newcastle. Of Retinosporas we noticed R. plumosa aurea, R. squarrosa, R. pygmæa, R. lycopodioides, &c.

The Committee are to be congratulated on the success of their large, varied, and fine Exhibition, and it is gratifying to state that their efforts are appreciated by the public.

I Do not wish to be unnecessarily critical about the judgments at this fine Show, but I want to make a few remarks upon what with a few alterations would be a remarkably good schedule with with a rew alterations would be a remarkably good schedule with noble prizes. First, £22 was given for dinner-table decorations, divided into £10, £5, £3, £2, £1—i.e., five prizes, but not one of the tables could strictly be called a dinner table—all merely dessert tables, and not one table, except one which had no prize was in any degree such as would be seen in noblemen's or gentlemen's houses in these present days. I suggest to the Committee, that instead of giving such large prizes merely to dessert tables with incongruous glass and fripperies of all sorts, they should divide the money for the future into dinner tables and dessert tables. The schedule runs, "The most tastefully decorated 'dinner' table;" each competitor allowed 10 feet by 5 feet 4 inches, and to provide a white tablecloth. So, too, I suggest that at a large show it is a mistake not to make all cut blooms dissimilar in their different classes. In Classes 10 and 11 Dahlias were distinct, but Class 12 runs, "Twenty-four Hollyhocks, not less than twelve varieties." Class 18, twelve Roses not less than six varieties. Class 16, twelve Carnations, not less than six varieties. 17 is right, six Selfs or Cloves, distinct; but other classes were open to improvement. In Class 21, twenty-four Pansies, not less than twelve varieties, Show Pansies and Belgian fancies were mixed together; and by far the two most beautiful lots of Pansies in the Show, one shown by myself, another by another exhibitor, had no prize awarded, but were cut out by the usual formal and dull (in my eyes) collection of the old show sorts, which I should never care to grow. No. 28 was right, twelve bunches or trusses or blooms, cut flowers, distinct from stove and greenhouse. The Gladioli in the second-prize collection were the finest in point of foliage and development of any I had ever seen, and I should certainly have placed them first; yet on the whole the judging of the cut flowers was remarkably correct. So, too, was the fruit-judging, with one or two exceptions, notably in the eight varieties of forced fruits, Mr. Westcott's second-prize collection being undoubtedly the best.

These remarks hitherto apply to Class A, open to all nursery-men and gentlemen's gardeners. The same remarks apply to cut flowers, also in Class B. Of the Hollyhocks in the winning collection I counted no less than eight blooms which had come off the same Hollyhock, or rather plants of the same kind; and though in order to see whether the judgments were good one of the Committee in the evening, after ten, when the Show was over, turned down all the cards and asked me to judge them. I only made one alteration in all the decisions, yet I am obliged to confess there was a terrible amount of sameness in these Hollyton and the same terrible amount of sameness in these Hollyton and the same terrible amount of sameness. hocks, &c., and other parts of the schedule not limited to distinct

In the matter of the fruits—and I certainly have never seen a better collection of fruit, especially Grapes and Peaches—it was different; every variety had to be distinct. But even here again was, to my mind, a great blot—large prizes given for forced fruits, and also for so-called hardy fruits; but on carefully examining the so-called hardy fruits I am certain not one was grown in the open air. Unless southern exhibitors had sent fruit from Jersey all had come from orchard houses. I make these remarks because I would suggest to the Committee another time to have classes for orchard house fruit and for fruit distinctly hardy, the exhibitors signing a declaration to that effect—that narry, the exhibitors signing a declaration to that effect—that the fruit was not grown under glass or imported from sunnier climes. I mention this because I took, merely as an extra addition to the Show, forty varieties of Apples, twenty-five of Pears, and twenty of Plums—all grown either as bush, espalier, or in some few cases as wall fruit—out of my garden in Yorkshire.

If only an alteration was made in the directions I have hinted at or rephase I wisht saw your than the contain that

at, or perhaps I might say more than hinted at, I am certain that this Show, which is already one of the finest in England, would be much improved. I ventured to say the same at the dinner when called upon to return thanks for the exhibitors, and I believe most of those present agreed with me.—C. P. PEACH.

BEDDING PELARGONIUMS.

THE general practice of planting Pelargoniums in beddingout so close as to make one uniform mass when they have advanced in growth has disadvantages which are especially obvious in such seasons as the present. The flowers as well as the foliage of plants treated thus are too flimsy to withstand continued with a season of the season of t continued rain, even in good seasons such as that of 1878. Having in that year a few Pelargoniums over after planting the beds intended to be so filled, I planted them in another

far enough apart for their full development without touching, and after the middle of the season they compared so favourably with the others, which had by this time grown into a mass, holding their flowers in the heaviest rain, while those on the others were beaten to pieces and showing every leaf fresh and green, when the lower leaves of those planted in the usual manner were turning yellow and rotting, that I determined to plant all my Pelargoniums that way in future. Managed thus they bear looking at individually, the plant alone being ornamental, independent of bloom; whereas, when planted as thickly as they generally are, a glance at the general hue of the bed is all they deserve and get. But, besides, there is positively more bloom on a bed of the thinly-planted in wet weather, more brilliant colour to be seen, than on a thickly planted one. Of course, for this plan of filling the beds good plants must be put out in the first instance, which can be easily afforded, as about half the usual number will do.—A. BOYLE.

GRAPES WITHOUT FIRE HEAT.

"A. C. M." seems anxious to know if Mr. Muir's Black Hamburgh Grapes were grown and ripened entirely without fire heat. This I do not know, but Mr. Muir will most likely reply to him; but let me state that we have a house of Black Hamburghs that have had no fire heat whatever, and the Grapes are nearly all ripe and of good colour and fine bloom. I have cut about eight bunches of fine fruit. Some of the bunches are not all colouring very well, which is, I think, owing to so much wet and cold. The Vines are planted outside, and have no inside border.

I can readily believe "A. C. M.'s" statement about the wineries in the south of London with no heating apparatus. With the late cold spring the Vines have been late in starting; but here the house I have referred to was full of greenhouse plants all the winter, and a temperature of 40° to 45° was maintained by hot-water pipes, but the Grapes certainly have had no fire heat beyond that, and that was discontinued as soon as the danger from frost was gone.

The Grapes in my early vinery—which is glazed with thick plate glaze, and of which I gave some account in the Journal last spring—did not colour well, and this I believe was in a great measure the fault of the thick glass, with so little sunahine as we had in early summer.—G. HILTON, Great Totham,

I AM much obliged to Mr. Muir for his reply, on page 229, to my letter that appeared in a previous issue of the Journal. I should not have entered further into the subject had not your correspondent specially requested me to state "how much importance I attach to starting the Vines with fire heat in April, and if I consider Grapes so assisted are ripened with the aid of fir e heat." My reply is, that the little fire heat applied at the time of starting the Vines makes all the difference between having ripe and unripe Grapes in a season like the present, on August 20th, the day on which Mr. Muir exhibited Grapes "ripened without fire heat" at the Glamorganshire Show. I have excellent proof of this, for in a house devoted to preserving plants in winter and growing them in spring, and where a little heat was applied throughout April, but none whatever after the 1st of May, Grapes were cut on September 5th, while in an adjoining house, in which no provision is made for heating, the Grapes are not yet ripe, though the utmost advantage has been taken of sun heat in both cases. Mr. Muir will admit the disappointment of the owner, and also the prospective loss, when he is told that it is doubtful if five hundred bunches will ripen at all. Last year, and in previous years, they ripened, but were not always quite so fine nor so good in quality as those in the house from which frost was excluded in winter, and a genial temperature was maintained in early

The natural deduction following Mr. Muir's statement, had at been unexplained, is that provision for artificial heat, even during a season like this, is a superfluity when Grapes are not wanted before Angust 20th; but I think, and I de not write without reasonable grounds for my opinion, that it is wise to make some provision for fire heat in case it should be required, and the better quality of the Grapes will more than defray the cost of the heating apparatus. I have seen Grapes in several unheated houses this year, but not in one instance have I seen them ripe in Angust; and if there is a case in Great Britain where they have ripened on the 20th of that month, and no fire heat whatever has been applied to the house at any time.

it will be worth recording, as it will prove there is at least one spot in the country where the weather has been salubrious during this extremely inclement season.—A. C. M.

WELSHPOOL HORTICULTURAL SOCIETY'S SHOW.

THIS was held in two large tents on the bowling green. A fine collection of plants not for competition was sent from the Powis Castle Gardens, kindly lent for the occasion by the President of the Society, Lord Powis, including remarkably well-grown examples of Lapageria rosea, Orchida, Palms, and various stove and greenhouse plants; also a collection of fruit containing Grapes, Pine Apples, Peaches and Nectarines very fine, Cherries, Pears, Plums, Currants, &c. J. C. Naylor, Esq., Leighton Hall, also sent an excellent and varied collection of plants. Mr. J. Jones, nurseryman, Shrewsbury, in a small tent adjoining staged sixty spikes of very fine Gladioli, a box of herbaceous Phloxes in good condition, Asters, bouquets, plants and Ferns, and a collection of Dutch bulbs. Among his Gladioli the most noteworthy were Admiral Willis, a red flaked and shaded crimson, a fine flower; Rgyptian King, maroon shaded and flaked mahogany; Kate, a soft pink flaked with deeper pink, very large flower and spike; Cluvia, salmon rose; Mrs. Mytton, red inside petals lighted with white, a very fine flower; Lord Berwick, orange scarlet, white throat; Mrs. Stanley Leighton, rose tinged orange, a lovely flower; Mrs. Wingfield, rose blazed carmine.

Among the plants for competition Mrs. Curling, Mrs. Willis Johnson, G. D. Harrison, Esq., Wm. Morris Pugh, Esq., D. H. Mytton, Esq., Mrs. Troughton, and Mrs. Llewellyn were the chief prizetakers. The Calsdiums from Mrs. Curling were particularly fine, as also were her Golden Hamburgh Grapes, for which was awarded the first prize. The first-prize Black Hamburghs were shown by Mr. A. Davies, and were remarkable for colour and fine berries, especially so as they were only grown in a house without the aid of artificial heat, but the bunches were small. The cut flowers were not numerous nor good. Fruit and vegetables were very good indeed, and many were surprised to see such fine fruit in so bad a season.

The cottagers' exhibits were displayed on tables in the open air, and a finer collection of fruit and vegetables it would have been impossible to imagine. Celery was splendid, and Potatoes were very numerous and excellent.

THE LONDON PARKS. FINSBURY PARK.

NORTH of the metropolis, situated between Highgate and Stamford Hill, is a tract of elevated and pleasantly undulating land (comprising nearly 120 acres) that was a few years past acquired by the Board of Works, and converted into a public park of considerable beauty. It slopes abruptly to the north, and the highest portion commands an extensive and agreeable prospect in clear weather, which, judging by the number of comfortable seats most thoughtfully placed there, must be greatly appreciated by the visitors. The Park is traversed by numerous excellent walks, some of which are formed of an asphaltic composition of tar, marble chipping, and shells, that is well adapted for the steeply sloping ground where gravel would be partially washed away by the rain; and although the colour is somewhat against it, yet it is always dry, firm, and clean. The shrubberies are at present in a comparatively young state, yet notwitbstanding their exposed position they are thriving admirably. Near the refreshment room is a small lake well stocked with waterfowl, and in the centre is a picturesque little island. There is also an extensive open tract of well-kept turf that is devoted to cricket and similar sports.

Flower gardening is well represented, and the effects of this unfavourable season were scarcely apparent; the majority of the Pelargoniums were flowering as profusely as could be desired, and the general vigour of the plants was remarkable. Their excellency in this respect is partially attributed by the competent Superintendent, Mr. Cochrane, to the purity of the air at that elevation and distance from the smoke of the City. The principal beds are in two opposite semi-elliptical turfed spaces, separated by a walk and backed with borders of low shrubs; the beds on one side of the path are generally similar to those on the opposite side, except that some of the central Pelargoniums are different. Next the shrubs are three large circles planted with Cannas, Abutilons, and Pelargoniums, with an edge of Lobelia White Brilliant and Echeverias. In front of them are several rows of variously formed beds, crescent-shaped, oblong, and polygonal, mostly planted with Pelargoniums in the centre, with an edge of Pelargonium Princess Alexandra and Lobelia pumila magnifica, the front row being occupied with tricolor and bronze

foliaged Pelargoniums, such as Lady Cullum and Marshal MacMahon. Two crescent-shaped beds with centres of Centaurea ragusina and Verbena venosa mixed, edged with Iresine Lindeni and Lobelia Omen, were extremely pretty. Some of the most noticeable varieties of Pelargoniums were Theocritus, a fine flowering scarlet, very effective; Cleopatra, an excellent pink, with large flowers of good substance; Edward Sutton, good dark scarlet; and Mont Bouge, very floriferous, medium sized truss of bright scarlet flowers. Immediately in front of the shrubs was a pretty ribbon border planted with scarlet and pink Pelargoniums margined with Lobelia pumila magnifica; the latter appears to have succeeded well this season, the colour is a fine bright blue, and the flowers most abundant.

In other portions of the Park were several tasteful beds, especially one of Fuchsis Sunray interspersed with Viola Admiration, and margined with Pyrethrum. Near the principal gate was a large scroll bed planted in a bright and graceful carpet design with Mentha Pulegium gibraltarica, Alternantheras, Pyrethrum, &c. Very attractive in the open turfed portions were the circles of Saponaria calabrica, Tagetes signata pumila, and Convolvulus minor beneath the numerous Mawthorns, and the bright pink of the Saponaria was especially pleasing in contrast with the green turf. Some small beds of Tropecolum Minnie Warne, a form with fancy variegated foliage, was also noticeable; and the ordinary styles of planting were relieved and varied by several herbaceous and mixed borders of Alströmerias, Phlox, Stocks, Centagress, Lupins, and Spirga filipendula.

The next and bright appearance of the Park generally is sufficient evidence of the care and attention bestowed upon it by Mr. Cochrane, who has had the management since it was first opened to the public; he is ably assisted in the flower garden by his thoroughly practical foreman. In the houses attached about 100,000 bedding plants are propagated annually, a portion of which are employed in decorating the gardens of the Thames Embankment. We have described this Park at some length, as it is the first time a notice of it has appeared

in the Journal of Horticulture.—L. C.

THE FUCHSIA AND ITS CULTIVATION.

[Read before the Sheffield Gardeners' Association by Mr. Thomas Foggin.] THE Fuchsia is beyond question one of the most graceful, howy, and useful of our flowering shrubs in the possession of the gardener or cottager, and certainly there is no other flower, with perhaps the single exception of the Geranium, for the loss of which it would be more difficult to find a satisfactory substitute. In the ease and facilities it affords for propagation it is absolutely without a rival among hardwooded or semi-hardwooded plants. The ease with which it is propagated, the beauty of its foliage, the abundance, gracefulness, and diversity of its flowers, its adaptation to the requirements of the window of the cottager, the conservatory of the rich, and the borders of gardens in town and country, have contributed in no small degree to secure for it the enviable position of everybody's plant. The value of the Fuchsia for outdoor cultivation is not so thoroughly appreciated as it deserves. This in a great measure arises from the mistaken impression that the fine hybrid varieties now in cultivation are too delicate in constitution to flourish in the open ground, though to some extent it may be the result of the modern practice so much in vogue of massing large quantities of a particular colour in the same bed or in the ribbon border. In the majority of cases where Fuchsias are used for decorating borders, or intermixing with other shrubs in the front rows of shrubberies, the old and by far less showy sorts are generally in request, owing to their supposed greater hardiness. Gardeners can scarcely fall into a greater error, or one which a single trial would more completely correct. Both double and single varieties are now

that for himself.

I will now describe the method of cultivation which I have for many years adopted, and which has always proved successful. But as my remarks are directed to those who are already conversant with the practical operations of gardening, I do not propose to enter into such minute details as would be necessary if I were speaking to amateurs or other non-professional admirers of this beautiful class of plants. Young cuttings may be struck with certainty at any season of the year. I have, however, found cuttings rooted from January to March the most useful when specimen plants are required, because at that time

cultivated to such an extent that it would be superfluous to

attempt to make a selection, as every grower will be able to do

they may be grown on without allowing them to receive a check, a consideration which is of the utmost importance where the object to be attained is a large and symmetrical specimen. The cuttings require good sharp sand, and a gentle, regular, and moist bottom heat. Under these conditions they will throw out roots in a few days. As soon as the roots are formed the young plants should be potted off into thumb pots, and in perform-ing this operation great care is required to avoid injuring the roots which at this stage are very tender. The soil I have found best is composed of equal parts of loam and sand with a small portion of well-decomposed leaf mould. The young plants should be kept growing in a temperature not exceeding 50° at night, but may be increased to 65° in the daytime with great advantage. If bottom heat can be commanded, and the pots plunged in it, the growth of the plants will be very considerably facility. siderably facilitated. Assisted in this way the roots will som reach the sides of the pot, when the plants should have a shift without unnecessary delay. The object of the cultivator should be to repot fraquently, but on no account to give more pot room than is absolutely required. Great care should be taken to prevent the plants from becoming pot-bound, as this would very seriously interfere with their free and vigorous development. These remarks apply with equal force to plants in all stages of growth, and unless special regard be paid to them all the efforts of the gardener will be thrown away, and disappointment will be the inevitable result. The final shift should be riven at least three months before the plants are wanted to bloom, and for this purpose equal parts of loam and old decayed manure form the best compost. The quicker the Fuchsia is grown the better it will break, which should be from the axil of every leaf, and the more symmetrical will be the shape of the plant. Avoid shading as much as possible, indeed the plants should never be shaded with the exception of a few days after each potting. Throughout the whole period of growth apply the syringe freely and often, and on no secount permit the plants to suffer by want of water, which checks their growth so much that no future attention can possibly remedy the mischief.

One of the main objects in preparing plants for exhibition is to get them in good form, and unless this desideratum be satisfactorily accomplished success cannot be attained, no matter how good the plant may be in other respects. To secuse this object much necessarily depends upon the taste and judgment of the operator, who must be guided in large measure by the peculiarities common to each variety under his care. In pursuing this end do not be afraid to take out the points of such young shoots that would interfere with the regular proportions of the plant, and which, by breaking back, would assist in promoting a uniform and beautiful specimen. Neglect of these timely precautions is probably the cause of many of those failures which so frequently annoy and dishearten the practical cultivator. That he has many and unanswerable reasons for his failure I willingly admit, but his reasons cannot be taken into consideration by the judges at horticultural

exhibitions.

If the plants do not appear to your satisfaction about two months before they are required for exhibition, and the blooms do not appear as though they would come out in time, give the plants a little stimulant; but in order to avoid exciting them into a rank and useless growth commence with a weak solution, and increase its strength gradually as you see they can take it. If you perceive it is too strong withhold it for \$ few days, and then renew it in a weaker form. You will soon be able to judge on this point, for immediately the direct rays of the sun play upon the plant the foliage will begin to droop, thus affording a sure sign that the plant has been excited beyond its natural and healthy condition. The cellular tissues do not in such cases contain the necessary amount of woody fibre, and the plants consequently cannot be expected to flower As a stimulant I have found nothing to equal profusely. blood, mixed in the proportion of half a pint to a gallon of water. There is nothing which will bring out such bright and healthy foliage, which is one of the chief additions to a plant in flower. An increase in the quantity may sometimes be made with advantage, but the use of such means must be applied While on the one hand there with discretion and moderation. is nothing which adds so much to the appearance of a plant as healthy foliage, there is nothing which detracts more from its beauty than bad foliage. The length of time required from the last pinching of the shoots to having the plants in full flower is about six weeks with most sorts, but this depends in a large degree upon the means and attention given by the

cultivator. The most effectual means of procuring good specimen plants is, after all, that the gardener should rise early and watch them late, in order to procure the finest specimens. Without such care all other means and appliances are of no avail.

NOTES AND GLEANINGS.

THE annual meeting of the Pelargonium Society was held at Chiswick on Tuesday last. There was a large attendance of members. Dr. Denny in the chair. The report and balance sheet for 1879 were submitted and adopted; Mr. Douglas was added to the Committee for the ensuing season. A discussion arose respecting a code of rules by which Pelargoniums should be judged, and the subject was referred to the Committee. W. B. Kellock, Esq., presided at the luncheon. Votes of thanks were unanimously accorded to the Royal Horticultural Society for the facilities afforded the Pelargonium Society; to Dr. Denny (Treasurer), Mr. Moore (Secretary), Mr. McIntesh (Chairman), and Mr. Turner, Slough. The excessive rain prevented the members from doing much work in the gardens, but a pleasant afternoon was spent by the company.

- At the Newcastle Show, a report of which appears in another column, a case of theft occurred which the Committee, for the protection of exhibitors sending fruit to their Shows, subjected to magisterial decision. A gardener named Forster was seen to purloin an Apricot, and on being searched fourteen specimens of fruit were found on him. Evidence of the fact having been given by Mr. Gillespie the Secretary, the solicitor engaged for the defence, while jtistifying the Committee for the steps they had taken, submitted that the fruit had been pocketed under the foolish supposition entertained by some people that the fruit at the close of a show could be taken by the visitors. In consideration of the man's previous good character, and as the fact had been made public, the Committee, with the permission of the Bench, withdrew the charge. The Magistrate in dismissing Forster observed that if the Committee had not taken a lenient view of the case it would have been very serious for him.
- It is a little surprising that the TURNIF-ROOTED BEET is not more generally grown in gardens for yielding early produce. We some time ago had some of this sent to us by Mr. Iggulden, and we never tasted Beet of better quality, while the colour was all that could be desired. The produce was much superior to that of the ordinary Beet that had been grown last year. In all gardens where sweet juicy Beet is required as soon as possible a few rows of this variety should be grown, as it is the earliest of all and as good in quality as any.
- MR. WARE, in his descriptive notes on hardy perennials and alpine plants, refers as follows to PRIMULA ROBEA:—
 "This is, without a doubt, one of the most beautiful Primroses in cultivation. It is totally distinct from anything known, and a first-class effective plant either for pots, the rockery, or the front row of the herbaceous border. It has a vigorous habit, grows with an amazing rapidity in any ordinary soil, is quite hardy (having stood out the whole of the past winter), and is exceedingly free-flowering; in fact, possesses every qualification to render it a favourite with the million. It was awarded a first-class certificate at South Kensington, and was the admiration of everyone. The King of the Belgians greatly admired it, and ordered a quantity of it for his palace at Lacken. The flowers are in large timbels and of a bright rose colour; small plants producing three or four heads on each."
- WE have received a photograph of a FRAME GLAZED on the system of Mr. Thomas Bickley of Birmingham, in which the sashbars (lead or metal), are placed crosswise of the light, and the glass is kept in position by lead clips instead of putty. It represents an excellent system of glasing without putty, and the houses we have seen glazed on this principle were light in appearance, waterproof, and durable. Only the bars are patented, and can be applied to structures of various forms.
- WE regret to have to announce the DEATH OF MR. W. WILSON SAUNDERS, F.R.S., late of Hillfield, Reigate, which took place at Worthing on the 13th inst., in the seventieth year of his age. Mr. Saunders was long favourably known as an assideous naturalist, and patron of science generally. The pursuits which he more especially cultivated were botany, horticulture, and entomology, and he was for many years an

active member of those societies which give encouragement to these pursuits. Mr. Saunders was for many years an active member of the Council of the Linnean and Royal Horticultural Societies, of the former of which he was Treasurer, and of the latter Secretary. A few years before his death he issued the "Refugium Botanicum," an illustrated work, giving portraits of some of the most interesting and neglected of cultivated plants; and he was also author of occasional papers on the Transactions of the various societies to which he belonged. Mr. Saunders was a man universally beloved by all who had the privilege of his acquaintance, and his loss will be deploted by a very large circle.

- —— THE GARDENS IN ST. PAUL'S CHURCHYARD, to which we alluded some time ago as being in progress, were opened on Monday last by the Lord Mayor. Their area is small, but the most has been made of the ground, and a great improvement has been effected by the introduction of gress, shrubs, and trees at the base of the noble building. The surface is pleasantly undulated, and is traversed by wide and firm winding paths that are composed of an asphaltic composition well calculated to stand considerable traffic. The beds containing the shrubs are slightly raised, and the latter chiefly comprise Aucubas, Hollies, Skimmias, Euonymuses, and Rhododendrons. The general effect is most agreeable.
- —— In the remarkably neat and well-kept grounds of the Royal Pavilion, Brighton, is a pleasing instance of CARPET BEDDING. A long scroll-like bed, composed chiefly of Mesembryanthemum cordifolium variegatum, has a design in Mentha Pulegium gibraltarica, somewhat resembling a branch that successively gives off large elliptical leaves; between the latter are small circles of Alternanthera amoena and A. versicolor, which are very bright in colour, and contrast well with the Mesembryanthemum.
- —— A CORRESPONDENT, "J. W.," sends us two trusses of HYDRANGEA both cut from one shrub; the one is pink and the other blue. There are at present many trusses of flowers open and others not so forward, some blue and the others pink. They are cut from a bush on the highest land in Kent.
- —— A CHESHIRE correspondent justly observes that "HOYA CARNOSA is one of the best of autumn-flowering greenhouse or conservatory climbers. A plant with us growing up the wall side of a conservatory about 30 feet high is densely covered with its pretty clusters of flowers. Being clean of mealy bug no plant is easier managed; indeed, it grows itself, and has but little training now that it has once covered the wall. As regards the root the same simplicity may be observed. The border is not above a foot in width and the same in depth, but has thorough drainage. This plant seems to flower better under the natural influence of light than when shaded, with not too much water at roots. Nicely mounted this is a very handsome coat flower."
- —— MR. JOHN GREEN, who has been foreman in the gardens of R. Hanbury, Esq., Poles, Ware, has been appointed head gardener at Sir T. F. Buxton's, Warlies Park, Waltham Abbey. Mr. Alexander Kirk, Ernespie Gardens, has been appointed gardener to J. Thomson Paton, Esq., Norwood, Alloa, Clackmannanshire.

DESFONTAINIA SPINOSA.

SINCE Mr. Luckhurst communicated his experience relative to the hardiness of this distinct and beautiful shrub we have had many inquiries respecting it. These will be best answered by the publication of the sunexed engraving, which well pourtrays the appearance of the shrub; and its full beauty will be appreciated when it is remembered that the flowers are tich scarlet in colour tipped with yellow, and the foliage dark glossy green. It was introduced several years ago by Messrs. Veitch, and has usually been grown in greenhouses, but now that its hardiness has been proved in the southern counties it will probably be more extensively planted in sheltered nooks and well-selected and prepared positions in shrubbery borders. Our great want in the shrubbery is shrubs which flower in

Our great want in the shrubbery is shrubs which flower in summer and autumn. We have a few, and only a few, and to these Desfontainia is a valuable addition. It is an evergreen; the dark green foliage, bearing a close resemblance to that of the common Holly, is thickly set upon a rigid, erect, bushy growth. The flowers come early in August, and continue in full beauty for upwards of a month, in clusters of long pendant tubes upon the ends of the branches. It answers well in ordinary garden soil, but should have an elevated well-drained

position, sheltered yet open, and is quite worthy of a special of Cornwall and Devenshire, where it attains a height of from

5 to 6 feet, which would seem to be its maximum in this country, several of the largest specimens showing traces of incipient decay. Hitherto it appears to have been regarded remarkable exception we have met with being a fine bedjef it

in the garden of Mr. George Williams at Scorrier, in the heart of the Cornish mining district, and yet it has been under cultivation in this country for nearly thirty years.

ACANTHACEOUS PLANTS FOR WINTER FLOWERING.—No. 3.

STEMONACANTHUS.

This genus contains but few species. It is characterised by the five-cleft calyx, by the corolla tube being slightly curved and somewhat club-shaped, whilst the lobes of the limb are unequal and usually reflexed; the capsule four to eight-seeded. The species are all tropical American; they are free-growing, and produce the finest effect when one year old if properly managed. But although so showy and effective when well looked after, they present a deplorable sight when neglected, and that so little attention as a rule is bestowed upon these plants has been one of the principal means of bringing them into disrepute. Pot in leaf soil, peat, loam, and sand in equal parts, and drain well. They may be grown in a cooler part of the house than the members of the order from West Africa.

& Pearcei.-An erect-growing plant with four-angled stems and opposite leaves, which are lanceolate, acuminate, slightly toothed at the edges, some 6 inches long, deep green above, and dull purple on the lower surface. Flowers axillary towards the ends of the shoots, forming a somewhat loose panicle; they are erect, slender at the base, swelling upwards, with a spreading limb some 2½ inches long, and bright scarlet. It blooms usually about February, and continues to give a succession of its brilliant flowers for nearly two months. Native

A macrophyllus.—This species is an older acquaintance than the one previously named. It differs principally in being a less robust grower, in the leaves being ovate-acuminate, and entirely lacking the purple colour on the under side. The flowers are scarlet but scarcely so large, and the inflorescence altogether is much more lax. Notwithstanding, it is a very desirable and handsome plant, usually flowering earlier than S. Pearcsi, and thus serving to keep up a succession of bloom. Native of New Grenada.

THYRRACANTHUS.

All the species of this genus hitherto introduced to cultivation are well deserving the attention of plant-growers; several however, being summer-flowering species, cannot be introduced here. We should advise the species quoted to be cut back annually and grown for some three or four years, when it will be best to substitute young plants. For soil, use good leaf mould, loam, fibrous peat, well decomposed manure and sand

in about equal parts.

T. Schomburghianus. — This plant was first distributed by the Belgian nurserymen by the name given by Planchou, T. rutilans, and by this name it is perhaps better known in English gardens to this day. The plant attains a height of some 2 or 3 feet, producing numerous branches. Leaves large, sendle, broadly lanceolate, tapering to a point, deep green above, paler below. Racemes 1 to 2 feet long, drooping and branched. Flowers tubular, upwards of 2 inches long, deep crimson in colour. It is at once one of the most desirable and effective plants it is possible to recommend, and in addition it is not only a winter bloomer, but could if required be kept blooming nearly the whole season. It seems to be widely distributed in South America. First introduced from British Guiana, afterwards from New Grenada.

T. indious.—A shrubby plant of considerable beauty, but totally different both in habit and colour of flowers to the previous species. The leaves are opposite, oblong-lanceolate in shape, tapering to a point some 3 inches long, and very deep green in colour ; thyrsus terminal, but instead of drooping as in T. Schomburghianus it is erect, many-flowered. Flowers large, funnel-shaped; colour white, more or less streaked with lines of purple. It blooms during the months of February, March, and April. Native of Northern India.

This genus is nearly allied to Barleria; it differs, however, particularly in having two peculiar bracts at the base of the calyx, both bracts and calyx being of a dull red hus. The species here introduced for its winter-flowering qualities may be grown into handsome plants in one sesson, therefore we should not advise old plants to be kept till the second year.

W. lateritis. - A shrabby branching plant, producing opposite

lanceolate leaves, which are furnished with long petioles about 2 inches long and deep green. Flowers produced on terminal spikes some 3 to 6 inches long, funnel-shaped, and deep red. It blooms during December and January. Native of Sierra Leone.

BARLERIA.

This is a large genus containing many very fine species which unfortunately have not yet been introduced in a living state. They are distributed over the tropical portions of both hemispheres, nearly fifty species being known as African, whilst the peninsula of Hindostan is very rich in members of this genus. They thrive best in good light soil, and as their growth is rapid we should certainly prefer young plants every

B. Gibsoni (fig. 29).—A neat branching ahrub, attaining a height of several feet; but handsome well-furnished plants

Pig. 39.—Barleria Gibeos

some 2 or more feet high may be grown from cuttings in a single season; and as these not only bloom freer than old plants, but produce the finest flowers, there is no advantage in keep-ing the old ones. The leaves are upwards of 3 inches long, ing the old ones. The leaves are upwards of 3 inches long, ovate-lanceolate and acuminate, deep green above, glaucous below, and somewhat corisceous in texture. Flowers funnel-shaped, produced in terminal and axillary spikes near the ends of the branches; lobes spreading, colour pale purple, the two upper lobes having a dark purple blotch in the centre. It flowers in midwinter. Native of Central India.

B. Machenii.—A species closely allied to the preceding, but a native of Africa and not India, having been introduced from Natal, a portion of the world to which the public attention has been so earnestly directed during the past two months. It is a very ornamental plant, attaining the proportions of a small ahrub. Stem slightly but very obtusely four-angled. Leaves somewhat ovate and subscute, recurved, about 8 inches long

and nearly an inch broad; colour deep green, and clothed on the upper surface with small close hairs, as also is the stem. Flowers not so freely produced as in the preceding species, but very handsome, funnel-shaped; the limb flat, some 2 inches or more in diameter; colour rich purple, with an intense deep purple blotch on each lobe. It flowers during early spring.

THE INTERNATIONAL POTATO SHOW.

JUDGING from the number of visitors attending the Show on the second day it is evident that Potato exhibitions enjoy a fair share of popularity. That they yield pleasure to many who inspect them, gratification to those who promote them, and increase the trade in new varieties of Potatoes of imposing appearance, whatever their quality may be, may be taken for granted, but it is questionable if they do more. The majority of the varieties grown for exhibition are not of superior quality when cooked. They are grown to be looked at, not to be eaten. The cultivation of those varieties can only be regarded as a luxury. And why should not such a luxury be indulged in? The kitchen garden to the Potato fancier is a source of enjoyment as great as the flower garden is to the florist; but as to improving the Potato as an article of food and ensuring a better supply in the markets the "International" has done little or nothing so far, and it may be well, perhaps, not to expect too much in this respect in the fittire. The Exhibition held last week, if not the largest, was, notwithstanding the inclemency of the season, probably the best that has ever been held by the Society. The tubers were more regular in size than at any previous show, and the polishing that formerly gave to many of them such an unnatural appearance appears at last to be abolished.

The finest-looking kidney Potato in the Show was International, fellowed closely by McKinlay's Pride. Beckenham Beauty is also a handsome tapering tuber, and Covent Garden Perfection is

The finest-looking kidney Potato in the Show was International, föllowed closely by McKinlay's Pride. Beckenham Beauty is also a handsome tapering tuber, and Covent Garden Perfection is fifie. Snowflake, flattish kidney, was admirably represented; this with such varieties as the old Ashleaf, Veitch's Improved Ashleaf, and the Boyal Ashleaf (all of which were very fine) combine attractiveness with high quality. Sutton's Magnum Bonum was in great force, and has won the position of being the greatest disease-resister of the year. Woodstock Kidney and Alpha (flattish) were attractive, as was also Edgeott Seedling. The finest round white variety was Schoolmaster; it is good also in quality in many soils. Porter's Excelsior followed closely. Woodstock round, selected perhaps from Woodstock Kidney, was pleasing in appearance, as was the new pebble-shaped variety, and Cosmopolitan a fine oval white. Bresse's Peerless was in fine condition. Amongst the mottled rounds Blanchard heads the list; Radstock Red closely resembles it, and Lye's Favourite is an excellently formed tuber. Grampian, red round, and Trophy, red kidney, are amongst the best in their sections. The new Vicar of Laleham is distinct in colour, very dark; as also is Early Purple Kidney. Beauty of Hebron is a very pale red and of good size.

All the prise collections were excellent, hotably Mr. McKinlay's, growh with the aid of Amies' manure, and there were several collections and debtes of great mariters in the content of the content mariters and these were several collections and debtes of great mariters and there were several collections are accellent.

All the prise collections were excellent, notably Mr. McKinlay's, grown with the aid of Amies' manure, and there were several collections and dishes of great merit not included in the prize list. The judging was generally very good, and the Show, that could only be briefly noticed last week, was a successful one.

THE OLD MARKET GARDENS AND NURSERIES OF LONDON.—No. 26.

In our treatment of the above subject it is natural, when referring to various localities, to make at least a passing mention of nurseries and market gardens which are of repute, though they may be of modern date. By inadvertence only have some of these been omitted, and I regret that in referring to Camberwell and places adjacent in a previous article I did not name the establishment of Messrs, F. & A. Smith at West Dulwich. A considerable portion of eight acres is covered with glass, and the firm has attained notoriety for its Pelargoniums, double Primulas, Cinerarias, Carnations, Azaleas, &c. Large quantities of Balsams, Cinerarias, Cyclamens, and other species are also raised for producing seed only. One house there, 200 feet in length, which has been sometimes filled with show Pelargoniums, is under such circumstances a sight not to be forgotten. This nursery has been in existence about thirty years. It can no longer be said of Dulwich that we may "lose the world amid its sylvan wilds;" but it has still much open ground in its vicinity. But it is singular to remember how large a part of Surrey lying within view of St. Paul's was field and wood when Queen Victoria came to the throne. The Crystal Palace has stimulated building operations thereabout, but as it has undoubtedly served to encourage horticulture I for one should regret to see it removed and its splendid grounds cut up.

In dismissing south London from further notice I would also add to the old nurseries that have been specified already that of Messrs. Rollisson of Tooting, some account of which has been given in this Journal, and which is very nearly a century old; it is to be hoped that having had its period of depression it will again flourish. At Forest Hill are to be found the later nurseries of Messrs. John Laing & Co., familiar by name to many readers, as is the nursery of Messrs. Peed & Sons of Lower Streatham, with others that need not be particularised. Few, if any, of our Surrey nurseries can date back their origin to the seventeenth century; but amongst those that have vanished Loudon mentions one in the hands of Mr. Russell at Lewisham which existed in Gibson's time, that is, early in the reign of William III. Lambeth has been previously described as once the abode of some of the early cultivators The name of Parkinson was omitted; he was probably a friend of Tradescant, and seems to have been famous for Myrtles, Oleanders, and various evergreens. Let it be noted, by the way, that "greens" in some books on gardening belonging to the seventeenth and eighteenth centuries does not mean Cabbages but evergreens! Then there was known to Gibson a Captain Foster of Lambeth, who though he did not keep what was then called a "sale garden," appears to have sold or exchanged the plants he reared. Gibson, when he visited that gentleman's garden, was informed that he had been successful in propagating Hollies by grafting, and he was shown a walk covered with trelliswork upon which were trained Vines which some years produced "much wine." At present, if Grapes do ripen in Lambeth, as may be the case, wine-making is not carried on there from home-grown fruit.
Worthy Mr. Gibson, with that want of exactness which was common amongst the authors of his time, does not always give us sufficient particulars concerning the nurserymen he has referred to. Where was, for instance, the garden owned by Mr. Pearson, who was so moderate in his charges and so straightforward in all transactions that he got "much chapmanry?" His successors in these days would say he sold at far too low a figure, for Gibson declares that his price for Cypresses 3 feet high was only 4d.! Versprit is another he mentions—seemingly a Dutchman from his name—who had grounds near London where he reared Hollies and other "greens." He was less moderate, since he got from Sir Henry Capel of Kew £40 for a couple of Lentiscus trees (Pistacia Lentiscus); just then they were esteemed great rarities doubtlessly. It might be conjectured from the circumstance of this sale that Versprit lived somewhere in the west of Middlesex, possibly at Chiswick, Hammersmith, or Kensington. An early patron of evergreens, Sir Stephen Fox, who did reside at Chiswick, is named by Gibson; this amateur had two Myrtle hedges upon which he bestowed the attention of having them covered up in winter with a wooden casing made for

the purpose.

Chiswick, near as it is to London, is still a pleasant spot to visit, and has attractions in addition to those presented by the gardens of the Royal Horticultural Society. Gibson, who saw it in 1691, would scarcely recognise the place in 1879; yet it is even now semi-rural, or more than that, though it does not exhibit a large expanse of open ground. But besides its garden spaces it has green fields, sometimes indeed rather environed with houses, where cattle pasture; and it has many scattered trees of venerable appearance, some of which may have been planted by the Dutchmen who came over in the reign of William III. But it had old trees long before his era, for Fuller tells us that he surveyed and admired a fine row of Elms that Dean Goodman set at Chiswick with his own hands when Queen Bess was on the throne. At Grove House near Sutton, an ancient estate with a history extending back to the early Henries, were numerous Walnuts and Chestnuts as old as the sixteenth century, probably, the fruit of which in favourable years produced £80 per annum. If we inquire about Chiswick when information becomes more reliable we find that in 1792 about 280 acres were in the hands of market gardeners, and rather more than that was covered with corn; 200 acres were used for grazing, and the rest of its 1200 acres belonged to private residences: one of these, and the most famous, was Chiswick House. The grounds which were attached to this estate, and which were at first laid out by the Earl of Burlington must certainly have held a control of the c ton, must certainly have had a special attraction to gardeners of the eighteenth century. Here was to be seen one of the first examples of the Italian style, but, possibly at the suggestion of Kent, the formality originally adopted in the lines of the walks was modified by the introduction of curves. Kent

who has been rather oddly called the father of modern gardening, was in the habit of stating that he improved his taste by reading Spencer's picturesque descriptions; yet, strange to say, his illustrations of that poet are by no means excellent. Chiswick House was also famous for its Cedar avenue, its Yew hedge 16 feet in circumference, its orangery, its rosery, its forcing houses, and its fruit garden, to which Gay has alluded—

"Where Pope unloads the houghs within his reach, The purple Vine, blue Plum, and blushing Peach,"

Chiswick does at the present time produce much fruit; the soil, a rich loam upon sand or gravel, being favourable, and the situation rather sheltered. If we turn out of the Brentford Road by the avenue of Limes leading to Chiswick House we find ourselves at its termination surrounded by orchards which extend to the east and west of the boundary wall of the Duke of Devonshire's grounds, while we have passed on our right the gardens of the Royal Horticultural Society. I am afraid that I am somewhat like the individual who was taken by a connoisseur to a picture gallery, but who, to his friend's diagust, expended all his enthusiasm upon the frames ! The gardens are deserving of commendation, yet I was admiring chiefly the wild growth that skirts them on one side. Here are trees planted long before the Society took the land (in 1923), and amongst other species are some of the finest Hollies and Hawthorns to be seen near London; and the hedges that divide off the market gardens in the vicinity have retained much of the reral appearance they possessed at their first planting, though in some instances those that edged the lanes in the "good old times" of George III. have had to give way to the more effective protection of brick walls and high palings. Part of the orchards, however, seem rather exposed now to depredators; but then Chiswick lies a little out of the track of the roughs who wander on Sundays in our London suburbs. Probably the market gardens at Chiswick were in their most flourishing state in or about 1840, since then the gradual spread of the metropolis has led to the formation of some new streets and

Though wishing to do justice to all we must put in promi-mence the name of Dancer, the firm which is also well known at Purser's Cross near Walham Green, having long done a large business in fruit and evergreens specially, as well as in general garden produce. There are many acres under their culture at Chiswick, and I observe that the system of undercriticle at Uniswick, and I observe that the system of under-cropping or double-cropping, opposed by certain modern authorities in horticulture, is yet followed to a considerable extent. Mr. Jessop of Grove Farm, and who also occupies some acres of land at Turnham Green, is noted for his excellent methods. The names may be mentioned in addition of Mr. Mills of Grove Park, and Mr. Munt of Hogarth Lane. The house, once in the occupation of the great painter of human incident, after sundry vicissitudes was taken by a nurseryman named Clark, and it is now, with a moderate garden attached, in the possession of a Mr. Coles, who appears for one thing to have made Musk a speciality, for that plant one is invited to purchase by a notice outside Hogarth House.

Gardens and orchards approximate to the road that runs from Hammersmith across Turnham Green to Brentford, near the venerable sign of "The Packhorse and Talbot," on both cides of the way is land under the cultivation of Mr. Bagley. Rather nearer to Turnham Green is the Chiswick Nursery, which is also in the main thoroughfare, and obtained its repute while it was in the hands of Mr. Glendinning; it is now Mr. Ewen's, and helps to encourage floriculture in the neigh-

bourhood.

Turnham Green farther westward has now market gardeners where it had farmers in the last century; amongst others might be specified Mrs. Sophie Collis, Messrs. Dawes, Hicks, and Jeffrey. There is some garden ground at Brentford where formarry, early in this century, the Messrs. Ronalds had extensive numeries. Mr. Pestridge of Boston Park Nursery is at present a producer of choice Pelargoniums and other exotics.—C.

DUPLICATE ROSES.

Now that the question of what have been designated "toomuch-alike Roses" has again cropped up the present would be a most convenient time for a free ventilation of the subject, and a favourable opportunity for soliciting the opinions of growers and exhibitors respecting the matter at issue. This is a subject that requires careful handling, because the greater part if not all of those "too-much-alike Roses" are fortunately very good ones, and to taboo them as duplicates should there be only one point of distinction between two varieties would be a loss to many exhibitors who have to exhibit stands of seventy-two and forty-eight. On the other hand, if the dif-ference between them is so slight that they cannot with any degree of certainty be identified, the fairest way for all would

be to have such written down as synonyms.

If one of the Secretaries of the National Rose Society would take the matter up and obtain the opinions of the successful exhibitors at the Society's Shows during the last three years, and submit these opinions to the Committee of the Society for their judgment and decision, there is every reason to hope that the question might be fairly and satisfactorily settled for some considerable time. As it stands it tells heavily on a consci-entious exhibitor, who would not knowingly set up one for the other even to spare himself the mortification of losing a place in the list of prizewinners; whereas it might be the means of adding several points to the stand of a less scrupulous one, who feels that by so doing he can nearly or quite defy detection.—OXONIAN.

WORK FOR THE WEEK.

PRUIT HOUSES.

Vines.—Vines in midseason houses from which the Grapes have been cleared should now be divested of their laterals down to the principal buds, which are to be retained for next year's fruiting, doing so, however, without injury to the old leaves, as upon their preservation depends the maturation of the buds, which should be plump and well ripened. Vines that have not as yet borne fruit may be treated in a similar manner, so as to secure by full exposure to light the hardening of the wood. A free circulation of air is necessary, and in the case of young Vines, or where there is the least doubt about the thorough ripening of the wood, fire heat will be necessary. When the laterals have been removed, the old mulching, if any have been employed, should be cleared off the borders, and a top-dressing given of turfy loam with about a sixth of decomposed manure and a sprinkling of half-inch bones. If the roots have not penetrated the mulching remove the soil down to them and replace it with fresh compost. In the case of inside borders afford a moderate watering, and allow those outside to have the benefit of October rains; and instead of adding manure to the loam, much the surface with 8 or 4 inches of fresh horse droppings, covering with dry litter or bracken by the end noise droppings, covering with dry little of bracker by the ent of October or early November. In the case of borders only partly made, a breadth of 2 feet may be added to the front, choosing a dry day for the operation, mulching with horse droppings, and covering-up as before advised. Every attention must be given young Vines planted this spring or early summer, keeping the foliage clean, removing all laterals, and maintaining a warm well-ventilated atmosphere until the canes are thoroughly ripe. Continue them from accommodity with a rather than formation. tinue sharp firing accompanied with a rather free circulation of air in houses containing Muscats and other late Grapes until the latter are ripe and thoroughly finished, when a gradual reduction of temperature must take place, otherwise the fruit will shrivel, a state of things that must be guarded against by not allowing the border, especially inside, to become too dry. Outside borders will in most instances he quite most approach and should be accorded. in most instances be quite moist enough and should be covered with lights preferably, or some other means employed to throw off heavy rains. Hamburghs and other descriptions of thin-skinned Grapes require frequent examination for the removal of decayed Grapes require frequent examination for the removal of decayed berries, damp being their greatest enemy. It should be prevented as much as possible by fire heat in the daytime accompanied by free ventilation, allowing the apparatus to cool down before nightfall, as night firing is not advisable. There must not be any further delay in the pruning of Vines intended to ripen their fruit by the end of April or beginning of May. Vines in pots intended for early forcing must be praned forthwith; shorten them to 8 feet, and prune the side shoots closely. To prevent bleeding dress the cuts with Thomson's styptic or patent knotting.

Figs.—Fig trees in pots which are subjected to early forcing should have the roots examined; and as it is not advisable to in-

should have the roots examined; and as it is not advisable to increase the pot room, remove a few inches of soil from the base of the balls, cutting back the roots, and replace with fresh fibrous of the balls, outting back the roots, and replace with fresh fibrous loam, adding about a tenth of old mortar rubbish and a sprinkling of crushed bones, good drainage being provided. Remove the loose surface soil and replace with the above compost, adding a fourth of well-decomposed manure. Afford a good watering, and place the trees where they can have plenty of air with shelter from heavy rains and frost. Fig trees planted out should be kept discrete that the latter that the statement was a discrete and d drier at roots, but avoid extreme dryness and a drier condition of the atmosphere will tend to promote the perfecting of the growths. As soon as the second crop in the latest house is all gathered the trees should be kept drier at the roots, and the house well ventilated in favourable weather. Any root-pruning or partial lifting should be done when the leaves show indications of falling.

Peaches and Nectarines.—The trees in late houses will need to have the shoots thinned out where too crowded, and those which have borne fruit cut out to a successional shoot at the base; this,

with free ventilation and gentle firing in dull weather, in cold localities, and with the growth strong, will assist in the ripening of the wood, which is of primary importance as regards next year's of the wood, which is of primary importance as regards next year's crop. The very late Peaches will not ripen this year unless we have a prolonged term of warm sunny weather. A little fire heat will be necessary to ripen them thoroughly. Trees that ripened their fruit in July will be approaching the resting period, the foliage now or shortly falling. They should be kept somewhat drier at the roots, but if the growth be very strong root-pruning or partial lifting should be resorted to before the foliage has all fallen. In the case of weakly trees the removal of the old so fallen. In the case of weakly trees the removal of the old soil and renewing with fresh turfy rather strong loam, with the addition of some crushed bones supplemented with a soaking of liquid manure not too strong, will improve them wonderfully. Trees that ripened the fruit in August and early September will need to have full ventilation, the shoots that bore fruit cut out, and where too crowded thinned as advised for late house trees, giving the foliage an occasional washing with the garden engine to subdue red spider; and if there is any fear of the wood not ripening employ gentle firing, avoiding, however, a warm close atmosphere, which would be more injurious than otherwise. There must not be any lack of moisture at the roots, as it is necessary that the buds be properly nourished as well as the wood thoroughly that the buds be properly nourished as well as the wood thoroughly ripened. Trees in pots required to be forced early must be attended to in top-dressing, removing the surface dressing and picking out the soil from around the sides of the pots, replacing it with fresh compost—turfy loam enriched with a fourth of manure and about a twentleth of crushed bones, giving a thorough watering. Trees in pots that have been forced several years may be turned out of the pots, disentangling the roots around the sides of the ball with fork as at to remuit of an inch or two of fresh soil being placed. and pots, discussing the roots around the sides of the ball with a fork so as to permit of an inch or two of fresh soil being placed around the sides. In top-dressing and repotting the soil can hardly be rammed too firmly, and in both cases should be performed before the fall of the leaf.

Strawberries in Pots.—The autumn fruiters should be encouraged with weak guano water, 1 oz. to a gallon of water, and in the case with weak guano water, I oz. to a gailon of water, and in the case of heavy rains and the fruit approaching ripening the plants should be placed in frames with abundant ventilation, which will improve the quality and colour considerably. Late-forced plants of La Grosse Sucrée as well as Sir Harry are showing and swelling the fruit admirably, both being considerably in advance of Vicomtesse Héricart de Thury, which though a free bearer is small, yet when well thinned the fruit is improved in size and small, yet when well thinned the fruit is improved in size and quality. Any of the autumn fruiters not required to fruit for some time yet may be retarded by placing them on a north border. There is nothing like a loose surface for Strawberries in pots, which prevents the soil leaving the sides of the pots, and admits of the water passing equally through the ball and moistening it thoroughly. A little dried horse droppings or cow dung rubbed through the hands, applied to the surface of the pots will keep all right there. Remove all runners as they appear, also weeds, and right there. Remove all runners as they appear, also weeds, and do not allow the plants to suffer through insufficient supplies of water. The plants should have plenty of space for the full exposure of the foliage to light and air, which is essential to a sturdy growth and plump well-developed crowns.

FLOWER GARDEN. To compensate in some measure for the absence of the usual brightness of the beds and borders no exertion should be spared to have the surroundings as nest and well kept as possible. The lawn should be well mown and rolled, the edges neatly trimmed, and walks made clean and smooth. The beds and borders also should be kept as neat as possible, looking over them frequently for the removal of decayed leaves and flowers and irregular growths. Violas have done splendidly this year. Cuttings of these should shortly be inserted, they succeed well in any sheltered border, selecting young growths from the base of the plants, and inserting them firmly in moderately rich loam surfaced with about half an inch of sand. Every cutting will strike provided they do not want for water. The propagation of Calceolarias will soon require attenwater. The propagation of Calceolarias will soon require asset tion. The frames for their reception should have a sheltered position and be placed so that the lights face the north. Place in the frames about 6 inches of loam with a third of leaf soil, surfacing with an inch of sand. The cuttings should be taken from the base of the plants, short stubby growths of two joints and the growing of the plants, short study growins of two joints and the growing points, cutting them transversely below the lowest and removing the leaves from that joint, only inserting the cuttings to the next pair of leaves, giving a good watering. The lights only need be employed to ward off heavy rains and in case of frost; whenever the air is mild too much air cannot be given. Violas may also be inserted in frames similar to Calceolarias.

The tender varieties of bedding plants will soon require to be placed under cover. Let those recently propagated be well placed under cover. Let those recently propagated be well hardened off by free ventilation; and though it is desirable to continue the tender plants out as long as possible, it is advisable to have some light protecting material at hand to throw over them in the event of frost, as many of the succulents are extremely difficult to winter if they become in the least injured. Similar remarks apply to the tricolor, bronze, and other ornamental-leaved varieties of Pelargoniums, which winter very indifferently if at all frostbitten. Mixed borders are still gay,

and to render them thoroughly enjoyable keep them as trim as possible. Dead and decayed leaves and flower stems should be possible. Dead and decayed leaves and nower stems should be immediately removed as they appear, placing supports to the autumn-flowering plants. Beds of Pinks may still be made, the earlier the better, digging-in 3-inch thickness of old manure; and beds of Pansies should be planted for spring flowering. Carnation and Picotee layers should be taken off and potted in pairs tion and Picotee layers should be taken our and potted in pairs in 4½-inch pots, employing turfy loam thoroughly reduced, with a fourth of leaf soil or old sweetened manure, and a little sand. They may be placed in a cold frame kept close for a week or ten days, and shaded from mid-day sun, afterwards exposing them fully. Any gaps in the mixed border occurring through the decay of annuals may be filled-in with Wallflowers, Brompton Stocks, and other biennials, so that they may become well established before with the state ways spring. lished before winter. It is not possible to have too many spring and early summer-flowering hardy plants, therefore plant them whenever suitable places are available.

whenever suitable piaces are available.

No time should be lost in preparing the ground for Tulips, Hyacinths, and other spring bulbs. Where manure is used it should be buried deeply and not allowed to come in immediate contact with the bulbs. The earlier that Winter Aconities, Showdrops, Scillas, Crocuses, and Narcissuses are planted the better. The latter are amongst the most useful and beautiful of spring-flowering bulbs, and should be actualized as the affect. The latter are amongst the most useful and beautiful of springflowering bulbs, and should be extensively planted, as they afterwards take care of themselves, increasing in size and beauty annually. Some of the best of the Ajax or Trumpet Narcissuses areobvallaris, maximus, nanus, Bulbocodium, bicolor, cernuus and its
var. flore-pleno, moschatus, rugilobus, bicolor, Horsfieldi, nobilis,
lorifolius maximus, and lobularis plena. The Pseudo-Narcissus,
and Telemonius plenus, the Mock Narcissus incomparabilis and
vars. sulphureus plenus, alba. flore-pleno, aurantiscus plenus, and vars. sulphureus plenus, alba, flore-pleno, aurantiacus plenus, and stella; Macleai; odorus and var. minor flore-pleno; and the Narcissus proper, of which the Pheasant's-eye is the type, are all excellent for cutting. The Polyanthus Narcissuses succeed ad-mirably in well-drained borders, and are very desirable for cutting from, as they succeed those grown indoors.

PLANT HOUSES.

Stove.—Dracenas, Palms, and other tender plants that have been employed for the embellishment of cool conservatories in summer must be removed to warmer quarters before the old weather sets in, or they will be liable to lose their lower leaves. The first batch of Poinsettias should now be placed in the stove where the temperature is kept at 60° to 66° at night, keeping them near the glass, and if supplied with weak liquid manure they will make a fine display; the strongest plants should be so treated, but the weakest should be kept in a house 10° less in temperature, affording water only to enable them to retain the lowest leaves, which are apt to fall if the plants suffer for want of water, whilst if overwatered they lose the roots, which is fatal to their flowering. These plants will come in late after the others have done flowering and be very useful. Euphorbia jacquiniæfiora must not be allowed to remain too long in a cool house, or its roots will periah. A portion of the plants may be placed in the stove for early flowering, whilst a later batch may be continued in a temperature of 50° to 56° at night. Centropogons, Sericographis Ghieshreghtians, and Thyrsacanthus rutilans, Eranthemum pulchellum, Plumbago roses, and P. coccines superba should also be assigned light positions in the store, and if a reservation be made of the smallest plants to be kept somewhat cooler a successional bloom will be Gesneras zebrina splendens and exoniensis should have light positions, and be kept well supplied with weak liquid manure. Similar remarks apply to Tydesas for winter flowering. The old Achimenes coccines ignes is very bright in colour, and makes a fine display in the stove in autumn, it being supplied with weak liquid manure occasionally. Lasiandra macrantha is a very beau-tiful purple-flowering plant at this season. If grown as a cool stove climber it is very effective. L. macrantha floribunds is of more compact habit. Achimenes, Tydesas, and Gloxinias that have ceased flowering should be placed in warm rather dry positions in the full light, watering them moderately until the tops have died down. Caladiums should not be kept dust dry after their leaves decay, nor must water be reduced too suddenly; they should be kept in the stove constantly with a little moisture at the roots so as to keep them sound, as when kept quite dry the corms are apt as to keep them sound, as when kept quite dry the corms are apt to decay. Ixoras that have yet flowers to open should have every care to preserve them as long as possible. Do not syringe more than is necessary to keep down insects, as too much moisture causes the blooms to be injured and drop prematurely. Allamandas, Dipladenias, Bongainvilleas, and Rondeletias that have a considerable amount of flowers set may be made very useful without in any way injuring their next was downwing only without in any way injuring their next year's flowering, only giving sufficient water at the roots to keep the plants from flagging, by which means the roots to keep the plants from beging, by which means the wood will ripen and the bloom open. The temperature of this structure should be maintained at 60° to 65° at night and 70° to 75° by day, with an advance from 10° to 15° from sun heat, admitting air rather freely, and reducing the atmospheric moisture.

Ferus for the most part will have completed their growths, and will be able to bear moderate fumigation without injury, it being important to keep down thrips, which at this time of year are

often troublesome. Take care to fumigate moderately two or three times at intervals of two or three days. Less moisture will now be necessary both at the roots and in the atmosphere. Shading may now be dispensed with, the temperature reduced a few degrees, and more air given. Adiantums cuneatum, gracillimum, &c., grown for affording fronds for cutting, should have a rest by withholding water and a reduction of temperature preparatory to their being started into growth early.

Roman Hyacinths, Paper White and double Roman Narcissuses

that were potted some weeks ago may be moved into heat so soon as they are well rooted, placing them near the glass so as to keep them dwarf, for when drawn they are not only unsightly as plants, but the flowers are not so durable. The temperature by artificial means should not exceed 55° by artificial means at the com-

mencement of forcing.

TO CORRESPONDENTS.

BOOES (Miss Chamberlayne).—Notcutt's "Handbook of British Plants," price 3s. 6d., post free from this office 3s. 8d., is a small compact volume for the pocket, and will, we think, answer your purpose well.

GARDEN PLAN (Gardenia).—We shall shortly publish notes relative to the above subject, from which you may probably gather the information you require.

MARUKU OR TI TREE (M. S.) .- This is the New Zealand name of Cordyline australia.

SREDLING PROOTES (Ashley Hextall).—Messrs. Turner, Ware, and Hooper have raised similar varieties from Prince of Orange or King of Yellows. Your variety will make a good border plant if having a yellow ground suffused with purple with small stripes of bright scarlet. Mr. Turner had a first-class certificate for a variety at the National Carnation and Picotee Society at Scatch W. Assistance of the Society at Scatch W. Assistance of the Society at Scatch Society at Scatch Society and Society at Scatch Society at Society So South Kensington in July, 1878. It, however, showed more scarlet than the flowers sent, with a better edge.

GRAPES NOT RIPENING (Disappointed).—If none of the Grapes are greener than those you have sent the bunches will ripen if you maintain a night temperature of 60° to 65°. The heat will also benefit the Vines by maturing the wood. It would have been better if you had applied a little more fire best in the spring so as to have accelerated their growth early in the year, and less firing would be requisite now, and the fruit would also probably have been better—that is, larger and more highly finished.

POINEETTIAS LOSING THEIR FOLIAGE (J. Spencer).—Provided you keep the roots in a healthy growing state the foliage will remain fresh, but if the roots receive a check either by cold, which is not infrequent at this period roots receive a check either by cold, which is not infrequent at this period of the year, or by a deficiency or excess of water, the leaves will inevitably turn yellow, and the plants will be in a great measure spoiled. Remove them at once from the frame and place them in a warmer structure, yet not in one highly heated, as a sudden change of temperature is often very injurious. A minimum of about \$8° will be safe for a week or two, then advancing to \$6°, increasing to \$5°. Keep the plants as close to the glass possible, and with due care you will have healthy foliage and fine heads of brilliant bracts

SOWING CALCEOLABIAS (E. Jacobs).—If you desire to have fine plants you had better purchase some that are now ready for being potted, as those raised from seed sown at the present time must necessarily be small, yet with careful attention and good cultivation they will flower next May. Sow the seed thinly on moist light soil, and place the pot in a frame or greenhouse. If you stand the seed pot in a deep saucer containing water, and keep the surface of the soil quite dark for a time, the seed will germinate without having to be watered. The moment the young plants can be perceived light must be gradually admitted, and eventually the pot must be placed on a light shelf near to the glass in a greenhouse. After the seedings appear the soil must be kept regularly moist; and it is better to apply the water very gently from the spout of the water pot to the sides of the seed pan, so that it floats over the surface of the soil in sufficient quantity to penetrate the entire mass, than to sprinkle the young plants with a ros, which often causes them to damp-off, on account of the soil being too wet on the surface and too dry below.

RAISEG LOBELLIAS (Decoming).—As you desire to raise a number of plants SOWING CALCEOLARIAS (E. Jacobs),-If you desire to have fine plants

ALISTIC LORELLAS (Deconsion).—As you desire to raise a number of plants from seed and possess a light greenhouse, but no stove nor heated frame or pit for accelerating their growth in the spring, you had better sow the seed at once. Sow and treat generally the same as we have advised E. Jacobs in reference to Calceolarias. The Lobelias may be left in the seed pan until February, when they will be ready for pricking-off, and will make much finer plants by May than you can obtain from seed sown in spring. They require to be wintered on a very light shelf in a house where the night temperature during the winter is about 45°. They will then grow steadily, and if not too thick will not be drawn.

CELERY LEAVES BLISTERED (M. M.).—Your plants have been attacked by the Calery fly (Tephritis onopordinis). The only remedy now is to re-move the worst portions of the leaves and crush the grubs in the others, and to dust the foliage occasionally with soot so as to render it distanteful to the flies, which deposit their eggs in the leaves.

STRAWHERRIES UNDER GLASS (J. E.).—As you wish to keep the plants in pots "all the year round," yet do not require to force them, pits or frames would be preferable to a house during the greater portion of the season, and after fruiting the plants should be placed outdoors. Until the plants commence flowering they will be better with the pots placed on sales

in a frame than on a shelf in a house. The frame you suggest will do very well, and will answer your purpose as well as a more expensive structure.

A shelf 5 inches wide will afford ample room for a row of 6-inch pots; but
three wider shelves, as shown in your section, would answer equally well for the
frame, elevating the back rows of plants on inverted flower pots as required.

PRIZES AT EXHIBITION (William Shattleworth).—Had you sent us a schedule with the rules of the Society and conditions of the Exhibition we should have been better able to have answered your question; but, as far as we understand the case, we think prizes of the nature to which you refer should be limited to the classes stated in the schedule, unless a notification was issued to the contrary.

CLIMBING ROSE AND CLEMATIS FOR TOWN GARDEN (Agricola).—As you wish to have Gloire de Dijon by all means plant it. Aimée Vibert will also probably succeed if you obtain healthy plants and plant them in good soil, syringing them frequently during the summer to keep the foliage free from sooty particles and insects. Clematis Jackmanni is the best variety for our purpose. It grows and flowers freely in suburban gardens near Lond

your purpose. It grows and flowers freely in suburban gardens near London. CINERARIAS WITHERING (X.).—As your plants have been well attended to and have not suffered by want of water we can only suggest that they have been kept too close and shaded too much, or that they have been potted too lightly in over-rich soil, which has induced growth of an extremely succulent nature. If the plants require a shift pot them rather firmly in sound loam enriched with about a third of very much decomposed manure, shading only when it is absolutely necessary, and admitting all the air possible, removing the lights entirely during nights that you are sure will not be frosty. Had you adopted this treatment sooner the plants, we think, would have been more sturdy and better able to resist a few hours' sun than they appear to be now. they appear to be now.

BARLY OABBAGES (E. T. H.).—You cannot have a better small early Cabbage than the true Atkins' Matchless; but it is too late to sow seed now for producing an early crop. The plants should now be quite large enough for being drawn from the seed beds and pricked out.

PHION DRUMNONDI FALLING (dem).—These plants usually thrive well in sandy soil, provided it is enriched with manure, and the plants are dwarf, stout, and healthy when planted out. They are more likely to succeed in such a soil than Verbenas. Your plants were perhaps not well prepared for planting out, and you also probably planted them too thinly. We have seen some very fine beds of these Phioxes this year, although the summer has been cold and wet.

PINES IN BEDS (A Constant Subscriber).—The best situation is the slope of a bank where the bottom is dry. If moderately elevated it may, if on a wet bottom, be more easily drained. If the soil is naturally of a good quality, and not more than three years under culture, it is well. The Pink requires a generous soil, moderately manured with thoroughly decayed stable litter. This, if the soil is good, may be laid upon the bed intended for Pinks 2 inches thick about October, and it should be immediately dug-in deep, and the soil well mixed with it. To accomplish this well it is of adfor Pinks 2 inches thick about October, and it should be immediately due-in deep, and the soil well mixed with it. To accomplish this well it is of advantage to dig the bed or piece of ground two or three times over. If the soil is heavy and the situation low the soil had better be entirely removed and the bottom of the bed well drained; then brings in some good light loam, the top spit of an old pasture that has been laid up, and turned over, and mixed with dung twelve months previously. Raise the bed from 4 to 6 inches above the natural level of the garden, keeping up the edges either with long slates or boards. The best time to plant is in the early part of September. If planting is delayed a considerable time after the pipings are rooted they become weak and long-legged, and are so tender that they suffer from the autumnal winds, and many perish if the winter sets in severely. By being planted in the blooming bed as early as September the plants become well established, firmly rooted, and even make some growth before winter sets in. By being well rooted the frost will have less power to throw them out of the ground. Plant across the bed in rows 6 inches spart, and 6 inches from plant to plant in the row. A little protection from vary severe freet will be useful. That protection consists in laying upon the bed between the rows a thin covering of either very short littery dung or one-year-old leaf mould. If neither of these is at hand a covering of decayed tanners' bark will answer the purpose. When the severe weather of winter is over see if any of the splants have been disturbed by the frost, press them down gently into the earth, and close it to them with the hand. The heavy spring rains will soon make the soil hard, and when such is the case stir the surface of the soil with a very short three-pronged fork, being careful not to disturb the sector of the server are three the server of the server are the park to be described the server are the proven and the server are the park to a careful not to disturb t soon make the soil hard, and when such is the case stir the surface of the soil with a very short three-pronged fork, being careful not to disturb the roots of the plants. The mulching, if very long, may be partially removed, and the rest mixed with the soil in the operation. This forking may be repeated as the plants advance in growth, and will be useful to keep down the weeds as well as keeping the surface of the soil loose and open. As the season advances and the heat of the sun becomes powerful a second mulching will be desirable. The former mulching was used to protect the roots from the frost; this second one is to shelter the roots from the heat and drought. The following are hardy and good varieties:—Regina, Annie Chater, Beauty, Bertram, Blondin, Charles Waterton, Clara, Disdem, Dr. Maclean, Rdith, Ernest, Bustoe, Broellent, Exquisite, Godfrey, Ivanhoe, John Ball, Lady Craven, Marion, Mrs. Waite, Picturata, President, Prince Proderick William, Superb, and Victory.

PROPAGATING DOUBLE WALLFLOWERS (A. Boyle).—The double yellow Wallflower to which you refer is very valuable for conservatory decoration in early spring, and equally so for the flower border during April and May. In order to have fine plants for pots the cuttings should be taken when the plants are flowering. At that time they produce an abundance of young growth, which if inserted in sandy soil in pots and placed in heat, watered and shaded—indeed treated precisely the same as Fuchsia or Verbens cuttings—they will strike in a fortunght or less. They should then be placed in a cooler position, and eventually be potted in small pots, kept close for a few days, and then be placed in frames until they can be planted out, or be shifted into larger pots and plunged in ashes in the open air. If the plants are stopped twice or thrice, but not later than July, they will form fine bushes and will flower early in the season. Other varieties, both double and single, may be propagated in the same way. Cuttings or slips of stubby side shoots inserted in sandy soil under handlights in June, kept moist and shaded to prevent flagging, also strike readily, but not so quickly as those placed in heat earlier, neither do they make such fine plants the first season. The slowest of all modes of increase is that to which you refer of inserting cuttings in a sunny position in the open ground in summer. We have grown these plants for many years and by inserting cuttings in April we do not lose 1 per cent. When the plants are planted out in early summer for lifting

in the antumn they cannot have a too exposed and sunny position, and the soil should be firm and rather poor instead of being rich and deep. The plants then grow sturdily and woody instead of tall and sappy, and are in the best condition for enduring frost in winter and for flowering early in spring.

DESPONTAINIA SPINOSA (W. S., Bradford).—Your situation is probably too cold for it out of doors, unless you plant it in a sheltared nook where the soil is specially prepared and the site well drained; but your safe plan is to grow it as a greenhouse plant, plunging it outdoors in a sunny position in summer. As the plant is healthy it only requires to have its growth matured to produce flowers. The spray sent is of the true species. We think it would not be admissible as a foliage plant at an exhibition. Other correspondents—"D. D., South Hants," "BRIGHTON," and "J. Collingwood"—will find the information they require in another column.

BOSE OF SHABON (H. Prince).—In some Hinglish localities the Hypericum calycinum is so called.

CAMELLIA CULTURE (A Subscriber).—We do not know of a special manual. Practical cultural notes are contained in No. 944, vol. xxxvi., of the Journal, which can be had, post free, in return for \$\frac{1}{2}d\$. in postage stamps, quoting the number required.

WEEDS ON LAWN (A. H.).—You will find it very difficult to eradicate the weeds. The best mode would be to dig up the lawn entirely, clearing out all the weeds possible; to enrich the ground with manure, adding lighter soil to produce a fine surface; and sow fresh grass seeds in the spring. Or a heavy dressing of manure applied to the lawn in winter, with such soil as you can obtain, mixed with lime, and in spring sowing a removating mixture of lawn seed, would effect some improvement.

EARLY WHITE GRAPE $(R.\ D.,\ Birch\ Dale)$.—So far as we can judge from the few berries sent your Grape is the Muscat of Alexandria, and its earliness is in some measure attributable to the sandy soil in which the Vine is growing. You can readily raise young Vines from it by inserting eyes in the spring, and we should do so, seeing that it succeeds and ripens so well under cool treatment.

HEATING GREENHOUSE (W. J. P. P.).—A small botier and pipes would be the most efficient means of heating the greenhouse, but a good paraffin lamp would keep out the frost, and with care would not seriously injure such plants as Geraniums.

GOOSEBERRY AND POTATO (An Old Subscriber).—The Gooseberry you name is possibly a local variety. We will write to Mr. Luckhurst on the subject. Woodstock Round Potato was exhibited at the Grystal Palace, but perhaps the tubers were selected from Woodstock Kidney. Early Rose, Bnowflake, and some others classed as Kidneys occasionally produce nearly round tubers. We shall be glad to hear from you as you suggest on the subject named in your letter.

PEACH AND NEOTARINE TREES UMPRUITFUL (L. R.).—If the trees make gross growth you may lift them with advantage, and re-arrange as you propose, removing them just before the leaves fall. An important point is to train the branches and shoots thinly, so that the wood can be well matured.

VARIOUS (Idem).—If you will state the age of the Vines, and whether they make very strong or only weak growth, we will endeavour to aid you. The Clematis requires more nourishment, the Box shrubs having impoverished the ground. Rither remove the shrubs, or apply a heavy dressing of manure. Rhododendrons, we think, will grow well in the soil you name.

INSECTS ON VINES (Inquirer, Astion-on-Mersey).—The emergence of a specimen from the larves sent some time ago establishes the fact that the species infesting your Vines is Tortrix pyrastrana. This is scarcely to be called a common British species, but it is sometimes plentiful where it occurs. The usual food of the larva is the leaves of fruit trees, most frequently the Apple or Plum. That it should be found feeding upon the Vine is singular. It is not likely, we think, to resort to that plant unless much at a loss for food.

NAMES OF PLANTS (Constant Subscriber).—1, Leyessteria formosa; 2, Spiresa callosa; 8, An Oxalis, but we cannot determine the species from the small sorap sent; 4, Spiresa prunifolia. (S. W. W.).—Impatiens Nolt-metangere. (Mac).—We reyret that we cannot name the Willows without seeing the cattins, otherwise we would be glad to assist you. (S. W. S.).—The very small specimens were so crushed and withered at to be quite un recognisable. (P. P.).—Too much crushed and withered for identification. Specimens should be sent in small boxes, and if the stems are wrapped in a little damp moss the flowers usually arrive in a fresh state. (Pen and Ink).—The Fern is Asplenium bulbiferum; the Begonia, Weltonieasis. The latter is of easy culture, and may be wintered in a greenhouse; if a little warm all the better. (V. G.).—1, Adiantum formosum; 2, Polystichum sp.; 3, Platyloma falcata; 4, Lastrea tenericaulon; 5, Peteris argyresa; 6, Pteris longifolia. (Citusi).—We think it is Citusi incanus. (P. P. P.).—As none of the specimens were numbered it is impossible to give their names so that you can understand them. (Subscriber, Suses).—1, Phylarthron comerense; 2, Æschynanthus Lobbianus; 3, Vinca alba; 4, Musseanda frondosa. (Mary).—As one of the specimens had no flowers and the other was much withered it is impossible to answer your question. The one partly in flower is probably Hieracium boreale.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

DRAINING OF HEAVY LAND.

WITHIN our recollection an immense extent of land has been drained; still, such a large area in the kingdom remains to be done that it is difficult to compute the area. It is, however, quite sufficient to know that certain large as well as smaller farms in various districts cannot be cultivated to advantage until draining has been effected. The causes of this may be various, for upon certain entailed estates we find that the pro-

prictor frequently does not feel sufficient interest in the property to induce him to undertake the work; in fact, oftentimes does not command sufficient capital for the purpose of such expensive undertakings as draining. Recent legislation has, however, given great facilities for such work, so that the cost may be charged on the estate. This circumstance has been the cause of large tracts of land being drained which otherwise might have remained in an unprofitable state for another generation. The home farms attached to the estates of noblemen and gentlemen have no doubt in most instances been drained probably at some former period; but when we recollect how different is the system pursued at present as compared with that in fashion or favour within our own experience, we contend that it is not always satisfactory for the home farmer to know that the land under his superintendence has been drained, because if it is still too wet for profitable agriculture the question of draining must be reconsidered. As an illustration of this matter we can refer to draining which we effected on our own property some fifty years ago. This laud has since required to be drained again, and this has occurred entirely owing to the want of knowledge upon the subject at the former period. In fact, at the present time there is some difference of opinion amongst surveyors, land agents, and others as to the best method of laying the land completely dry under the varying conditions of soil and surface. It is, however, on this occasion the task we undertake, and will endeavour to lay before the home farmer not only the result of our own experience in the draining of land under our management, but likewise to bring forward and introduce the opinions and practical knowledge of others in support of our own, in order that what has previously proved an error of judgment may now be avoided, so that in future the work of draining the land, at all times involving a serious outlay, may prove a good investment, not only for the present time but in the future also.

We will consider heavy land as including all strong soils, and these vary immensely, because in some districts we find red clay, yellow clay, and blue clay, and other gradations of colour; either of these are oftentimes when unmixed with gravel very tenacious and hard when dry, yet when wet they resemble putty or beeswax in texture, and will hold water almost like an earthenware dish. These are some of the most difficult soils to make dry by draining, but still it often depends upon the soil which underlies and the depth of the clay above it. We will therefore endeavour to explain the best method of laying land dry by draining which has hitherto proved unprofitable in cultivation, either in consequence of its never having been drained, or because it has been done in an imperfect manner. We shall not upon the present occasion refer to the draining of pasture lands, believing that it will be the better plan to refer to them separately and at a future time.

The first remarks we have to make refer to a bygone period when draining was in its infancy, which is shown by the various simple methods resorted to, such as draining with stones, with fir bavins, with alder and other poles, wedge draining, and also the mode of plug draining, whereby the clay land was either laid partially dry or was subject to a very short period of effective operations. Again, although our own tile drains laid in fifty years ago were the means of only partially drying the land, it is one of the first points we have to consider now, because it cannot answer to enter into an expensive process like land draining and reap only a partial benefit. The home farmer must therefore be satisfied with no system which will not completely dry the land at all seasons. Now to illustrate the case, we have seen numerous instances where all the above-named plans of draining had been done at some former period, yet they had all become inoperative from various causes. The stone drains had become blocked by earthy deposits, the fir boughs or bavins the same, the slder poles had become decayed and useless; the wedge and plug draining having been formed from the soil itself having been ingeniously tempered and formed into drains were in time, through the action of the water upon the soil and also by the burrowing of moles, rats, rabbits, &c., rendered useless. Even the tile draining became inoperative in some cases from the drains having been laid too skallow, others placed in the wrong direction and often without a proper outfall; and as tile draining was formerly done by the tile of a horseshoe shape with a flat tile to rest upon, yet in many cases in strong clay the mistake was made of omitting the bottom or flat tiles, the drainer probably thinking that the hard strong soil would bear the pressure upon the tile of the superincumbent earth, but we have never seen it answer the purpose even in the stiffest soils to omit the flat tile at the bottom. And, again, where the drains, although properly laid, in many cases they were laid in the wrong direction, or too wide apart, or too shallow, and portions of the surface soil proved to have been left too wet for profitable culture. This in several respects represents the draining done upon our own land previously to the year 1830; we therefore determined upon redraining certain fields of a clay soil, and thus avail ourselves of the advantages offered by the use of pipe tiles as soon as they first came into use.

Our first illustration is a field of 11 acres having a moderately good fall from the upper to the lower end. The soil is strong loam with a brick earth, the subsoil having a few stones in it with veins of sand running through it, and at the upper end the bottom of the ditch exhibited quicksands at the depth of about 6 feet. In the winter of 1827 and 1828 this field was drained with such and flat tiles at 2 feet deep; the drains were put in herring-bone fashion as it is called—that is, a leading drain laid down the incline and 6 inches deeper than the branches, which were placed 24 feet apart and across the fall of the land; and herein lies the mistake, for if all these drains had been placed in the same direction as the leader and placed at 24 feet apart this would have laid the land much drier. One important matter in this case was overlooked—that is, the quicksands existing at the top of the field, for that evidently was the chief cause of the land being too wet, as the water originating in these sands fed the subsoil throughout the field, and it rose to the surface through veins of sand, and thus injured the whole field. This field has been within the last twenty years redrained upon another system—that is, the quicksands at the upper part of the field have been drained by a deepercose cutting varying from 6 to 7 feet in depth, and the remainder of the field has been laid dry by drains 8 feet deep at 24 feet apart, with 2-inch pipes, the quicksands drain being laid with 3-inch pipes and collars to prevent the sand entering the pipes with the water. This is now a fine field of land, and quite dry enough for all agricultural purposes, including the feeding of sheep thereon in the winter months.

The next lesson which we ask the home farmer to learn will be that of strong land upon chalk, the depth of the clay varying from 4 to 5 feet above the chalk subsoil. The clay in our field of illustration is of the most tenacious kind without any veins of sand, or any other variation at all in the surface, not even stones. Now, this clay is so tenacious that the horse tracts during cultivation, if the soil is moist, will hold water like a dish; it was therefure thought desirable when this land was drained to place the pipes deep enough to cut through the clay entirely so as to reach the chalk subsoil, and in order to enable the water to reach the pipes the drains were filled in up to the top with rubble chalk, and no doubt this greatly facilitated the passage of the water from the surface to the pipes. The drains, if I recollect rightly, were placed about 18 feet apart, and the land was laid sufficiently dry at all seasons for agricultural purposes. It did not so far alter the land as to make ft a friable land, for it was a stiff clay after all, but worth nearly double the rental it had ever been before draining; but the most curious part of the subject of draining fixis field remains to be told, for although the 2-inch pipes were properly laid no water ever ran through to the outfall; instead of that the water evidently sank into the chalk soil and dissippared. Now, the lesson to be learned in this case is that the adjoining field of the same sort of soil was drained in the same way without the tiles, and it proved equally effective.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour should now be applied in autumn culture, or in case steam power is employed some horses will still be required in harrowing, rolling, dc., also in carting away couch grass and weeds, which may be brought to the surface after scarifying. The harvest being so late will hinder the work of autumn culture to some extent, in which case it will be advisable not to take in hand too much land for that purpose. We recommend that the land intended for mangold and for potatoes should be prepared if no more can be done, because it is quite impossible in ordinary seasons to clean the land by culture in the spring in time for the seedling and planting of early crops like these. Laying out the dung for wheat should next be attended to, but upon all dry soils sown out of lea it may be deferred until heavy rains commence and stop the autumn culture. The seeding also of trifolium and winter vetches must be done at once, if it has not already been effected. We fear that in some districts the harvest and work of the horses in connection with it will not be completed for several weeks, and our allusions to autumn culture, seeding of green forder crops, &c., have only been made contingent upon the fact that the horses may not be required, or be occasionally at liberty.

before the harvest is over. It is only in a few instances, owing to the late and showery harvest, that the threshing of corn can be done in the field; but for the portion of corn which is required first, for either sale or use on the farm, it is a good plan to cart to the threshing machine in the field, and either rick or truss the straw as may be required as it comes from the machine, as it saves the risk and expense of stacking, thatching, &c., and when the corn and straw are both dry the latter never weighs better than when threshed in the fields. We have seen this done during the when threshed in the helds. We have seen this done during the present harvest with great advantage. When the straw is required for cattle fodder it is a good plan to have it spiced. The cheapest article now used for this purpose is that sold by T. Bowick & Co., Bedford, called the "Botanic Flavourer," and the cost per ton of straw where properly applied, is not more than 2s. Straw stacked and thatched having been spiced is not only more attractive by the aroma of the spice, but is increased in feeding value, for the cattle, owing to the vegetable compounds contained in the spice. This is the time of year for stocking arable farms with sheep in various districts for winter fattening, and for breeding lambs to be fattened in the spring upon roots, &c. The season having been so wet we understand that a large portion of the sheep now slaughtered by the butchers for mutton are actually suffering from rot or coathe more or less, with large numbers of flukes in the liver. We must therefore recommend the home farmer to use extreme caution in the purchase of his stock of sheep for winter feeding, and take always a written warranty of soundness from the seller at the time of purchase, and also make soundness from the sener at the time of purchase, and site lake a careful inquiry as to the soil and district upon which the sheep have been kept during the summer. If from perfectly dry land they would be tolerably safe, but the diseased sheep to which we have alluded have been kept chiefly in different districts where pasture land prevails.

Hand Labour .- We fear for some little time more work will be equired than can be got through in good time. having been so unfavourable for the harvest has been the cause of a continual change of work, oftentimes in the course of a single day. The hand-hoeing of root crops of all kinds has been ineffective owing to the continued rains, and in many cases where the roots are advanced in size and the land very weedy it is quite hopeless to clear it now, and the roots must remain as a short crop for use, and the cleaning of the land be deferred to a future opportunity, most probably not before the spring of next year. opportunity, most probably not before the spring of next year. Store pigs and breeding sows may now be kept carefully looked after upon the corn stubbles, but they should be properly rung, especially when they are allowed to feed in the barley stubbles seeded with clover. Nearly all the flocks of sheep, particularly in the pasture districts, are suffering from foot rot or lameness of some kind. It is often called foot-and-mouth disease, and has been treated for that complaint in many instances but we have reason treated for that complaint in many instances, but we have reason to believe that it is frequently nothing more than an attack of foot rot brought on by the continual rains. Let the cause, however, be what it may, the disease can only be kept within bounds by constant and daily treatment, by paring and dressing the feet with mild caustic remedies. The land should now be set out for sowing the seeds for the production of green fodder crops, such as rye, or winter oats, and vetches. This should not now be delayed, because these crops are the more valuable for being early as spring food for sheep and cattle. This is now the time for purchase of the horned Dorset and Somerset ewes for the production of early lambs, and upon the home farm and park lands they are not only lambs, and upon the home farm and park lands they are not only ornamental but also very profitable when properly cared for. The fairs for this stock are held at Appleshaw and Weyhill in Hampshire, and the various fairs in their native counties are held chiefly in the first week in October; and the breeders of this stock take care to turn the rams with the ewes at a time when it will insure the period of lambing to commence immediately on the arrival of the ewes at their new home after the fairs. In fact these ewes are often held over to breed from upon the dry land farms in the home and south-eastern counties, and these are now just beginning to drop their lambs, and under these circumstances are sure to yield a large number of twins.

CLUB-ROOT FUNGUS (Plasmodiophora brassicæ, Wor.)

THERE can, I think, be little doubt that the fungus or vegetable parasite discovered by M. Woronin, and by him named Plasmodiophora Brassics, is the true cause of what is called clubroot and finger-and-toe in turnips, cabbage, charlock, and other cruciferous plants. The great importance of the turnip crop in the husbandry of this country gives the investigation of this fungus an interest of a highly practical and economic character. We are here in the presence of an enemy the strength of which is certainly on the increase, and which threatens, if no countervailing strategy can be devised, to render the turnip crop as uncertain and precarious as the potato crop has been rendered by another parasitic fungus, the Peronospora infestans.

The observations of Woronin were made chiefly on the cabbage,

The observations of Woronin were made chiefly on the cabbage, and in reference to the great destruction caused in recent years to the cabbage crop in Russia, and more particularly in the market gardens around St. Petersburg. My own repetition of these obser-

vations has hitherto been chiefly confined to the turnip, including only such comparisons with cabbage, charlock, and mustard as That it is so. showed that the parasite was the same in all cases. however, is an assumption based only on the optical data patent to the microscope. The plasmodic masses ramifying through to the microscope. The plasmodic masses ramifying through the cell tissues of the roots have the same appearance in all these plants; while the ripe spores which form the final stage of the plasmodium, and which are globular in shape and very uniform in size, have also in all cases the same dimensions: thirty-four

millions of them can lie upon a square inch.

It would be impossible to go into the whole subject at present. I shall therefore select one branch. Considerable interest has recently been awakened in the salmon disease. That disease is supposed by some to be produced by a fungus, the Saprolegnia supposed by some to e produced by a rungus, the saprolegna ferax. By others it is supposed that the fungus is consequent on the disease. And hence arises in this and in other cases the need of a clear conception of parasitism, which may be defined as the state of a living organism living upon the life of a living organism. In any given case in which a fungus is found locally associated with an organised body in a state of vitality, or in a state of dis-integration, the question may be raised, Is the fungus a parasite? Is it a fungus which requires a living host for its growth and development? Is the club-root fungus a parasite? Does the club-root fungus demand a living and healthy plant in the tissues of which to work out the cycle of its life?

The true answer to this question, if it can be given, is highly important to agriculture. For, if it shall appear that a weak, or important to agriculture. For, if it shall appear that a weak, or sickly, or decaying plant is required as the proper soil of the clubroot fungus, then this fungus is not a parasite, and its presence merely indicates antecedent disease arising from some failure of practical husbandry. Something has been done, or something has been neglected, in consequence of which the turnip plant and other plants fall into a state of disease and then become the prey of the clubroot from the state of the state.

of the club-root fungus. But, on the other hand, if it shall appear that the club-root fungus is a true parasite, a plant living upon the living substance of another plant, then this fungus assumes a different attitude towards agriculture. Conditions calculated to secure in its absence towards agriculture. Conditions calculated to secure in its absence a healthy crop of turnips are of no preventive value. If the fungus is a parasite, the proper nidus which it requires is a living and healthy turnip. That there are numerous fungoid parasites waging perpetual war upon living plants is well known, but is not popularly accepted in its full significance. We cannot suppose from any facts known to us that all the potato crops in the country must be in a state of disease and decay before becoming the prey of the notato fungus. The grasses do not require to be in an unof the potato fungus. The grasses do not require to be in an unhealthy condition before being attacked by ergot and smut and rust; and there seems little doubt that the Hemiteia vastatrix, the fungus which destroys the coffee crops, is also a true parasite, attacking the healthy leaves.

Now, what is the nature of the evidence that the club-root fungus belongs to the class of true parasitic fungi?

The root of the turnip is frequently attacked at a very early stage. Turnip seeds may be sown, and the plants matured, in a same in water. I have found each thus arms and with the saucer in water. I have found seeds thus sown, and with the water mixed with the pulverised turnip clubs of the previous year, to have their roots attacked when only about the thickness of onehundredth of an inch. But in such circumstances the tap-root itself, even where no cause of disease has been introduced, never attains to any kind of bulb, or to a thickness beyond two or three hundredths of an inch; so that when attacked by the fungus in water, the portion of the root affected, not growing so rapidly as to afford room for the disrupting plasmodia of the fungus, is a readily billed and consist of disintentian. But the always, is speedily killed and goes into disintegration. But the club ceases to enlarge whenever the root dies. Could the granular plasma of the fungus grow upon decaying matter, there seems no reason why the club should not go on enlarging after the death of the root. But if it is a parasite the reason is plain—it cannot live on dead

It is, however, when the seeds of the turnip are planted in earth that some of the phenomena can be best observed. I find that the ripe spores of the fungus exist as spores from one season to another. During the intense frosts of last winter (1878-79) they remained as bright and clear as when newly matured. They are not to be killed by being turned up to the frost. I mixed a quantity of the rotten clubs of crop 1878 containing these spores with garden mould in which no disease existed, and with the mixture garden mould in which no unsease calesco, and some having filled a number of pots, some having drainage and some having filled a number of pots, some having drainage and some having to be in any way close bottoms. Good turnip seeds, not known to be in any way defective, were sown in the pots. All the resulting plants became at an early stage excessively and fatally clubbed. The two largest pots, having the ordinary flower-pot drainage and standing in the open air, had each between thirty and forty plants all clubbed, while the turnips in the same garden mould beside them were quite free of disease. The plants in the pots which had no drainage, and which from the wetness of the season were frequently scaling. and which from the wetness of the season were frequently soaking in water, had a large development of lateral roots; they did not grow so rapidly as the plants in the drained pots, and the clubs did not attain to so large a size.

Now there seems to be no reason whatever for assuming that

all these plants were first in a state of disease before being attacked. all these plants were first in a state of disease before being attacked by the Plasmodiophora. Indeed, it was quite evident that the strongest and healthiest plants were the most favourable to the full development of the fungus. The tissues of a small and feeble plant are speedily disrupted, the cells are choked with granular fungoid matter, and the plant dies. In stronger plants the contest goes on a little stronger. The attack is frequently made at two or three centres; and in many cases even upon a slender root, the club is chiefly developed on one side. Where there are lateral roots coming into the tan-root above the clubs the plant goes on roots coming into the tap-root above the clubs the plant goes on growing for an indefinite length of time, for the matter of the fungus does not appear to be carried by the motion of the sap, rungus does not appear to be carried by the motion of the sap, but it extends by growth from particle to particle. Where the attack is early and of a severe character the plants are killed when young. Where it is less severe, a slow and local process of clubbing goes on during the whole season, and the bulb arrives at fair dimensions. But it is remarkable that, while turnips and cabbages are very often killed outright, charlock and mustard usually go on to flower and seed in defiance of considerable clubbing. But in all cases whenever the plant dige the club cases. usually go on to hower and seed in denance or considerable clubbing. But in all cases, whenever the plant dies the club ceases to increase in size, and in all probability the fungus, which is the cause of the club, is not the direct cause of the subsequent rotting at all. A club taken and dried will preserve for any length of time. But the clubs are an easy prey to atmospheric disintegration, and to fungi and infusoria which revel in dead matter.

The evidence seems to me to show that the healthier plants are not the least liable to the attack of this fungus. In going along a drill of turnips in which nearly every plant is affected, there seems nothing to imply that the few which escape were in any respect healthier than the many which are destroyed. Certainly respect healther than the many which are destroyed. Certainly the balance of probability is in favour of regarding the Plasmodiophora Brassics as a pure parasite, demanding a healthy living host for working out its career from a spore to an amoba, from an amoeba to a plasmodium, and from a plasmodium back to spore again. I am not perfectly convinced that this is the exact course, but Woronin's conclusions are not to be modified without mature consideration.

mature consideration.

It would thus appear that the turnip husbandry of this country is in presence of a destructive parasite. Hitherto the grower of potatoes has stood helpless before the forests of Peronospora infestans, with stems small enough to come out in half-dozens infestans, with stems small enough to come out in half-dozens from the stoma of a leaf. And here is a fungus of an altogether different and less palpable type, devouring the turnip crop with perfect impunity. Can anything be done to stop its ravages? A reduction in the frequency of the turnip crop by permitting the destruction of the germinating power of a greater number of spores, would undoubtedly restrict the virulence of the disease; spores, would undoubtedly restrict the virulence of the disease; but this is not properly to cure it, but to give way before it by withdrawing the crop and foregoing the profits to be derived from it. Experiment shows that the disease is not a mere result of peculiar modes of tillage or of characteristics of the season, though these may promote or retard its growth, but that it is a plant, one crop of which arises from the seeds of a previous crop. Probably under existing systems of rotation, wherever the club-root fungues. has got a firm hold, extermination is impossible. Other questions then arise not belonging to the purpose of our meeting. Who knows whether it may not be good for agriculture that such fungi as those which partially destroy the potato and turnip crops cannot be exterminated? Thanks are undoubtedly due in certain not be exterminated? Inames are undoubtedly due in certain parts of our country to the Peronospora infestans for destroying a means of subsistence which was over-abundant without enterprise and energy, and left the better resources of the cultivators to waste themselves in idleness. And who knows but the prevalence of Plasmodiophora Brassics may divert the course of agriculture into a new and more fertile direction?—(Read by Mr. S. WILSON before the Cryptogamic Society of Scotland.)

JAPANESE BANTAMS.

THERE are many poultry fanciers in the truest sense of the word who have but scant accommodation for their pets, and on whose premises it would be absurd to attempt to keep large fowls. whose premises it would be spenit to severally to any first parts, or There are, however, many little corners, small unused yards, or There are, however, many little corners, small unused yards, or There are the several corners and where Rantams can run and be happy. To neglected garden ends where Bantams can run and be happy. To those looking out for a breed as tenants for some such little nook we recommend Japanese Bantams. Long ago we used occasionwe recommend Japanese Bantams. Long ago we used occasionally to see a pair or two at a show, and must confess that we did not admire them. At first sight they seem to have a stunted dwarfish look from the immense size of their combs and tails; but like many other birds, and people too, they must be known to be appreciated. We have given them a fair trial, and certainly find them to be some of the quaintest and most amusing of Bantams, and peculiarly suited to a garden, for their legs are extremely short and they hardly can soratch if they would. In size they are slightly larger than the general type of exhibition Bantams, or rather what exhibition Bantams used to be, for we have lately seen prize Sebright and Game Bantams which would at one time have certainly been disqualified for their large proportions. Japanese, however, appear larger than they are from the great development of their feathering, especially of the cock's tails.

thrown back till it almost or quite touches his immense tail. The tail itself is not sickle-shaped, at least the longest feathers are not, but carried somewhat erect, and with a multitude of side feathers which make it very handsome. Their legs are yellow and very short, almost as short as those of Dumpies. Their colour and very short, almost as short as those or Dumples. Their colour is very various; formerly none but pure white, or white with black markings were seen, now, however, they are seen of various colours. Among the many curiosities brought home by Mrs. Brassey in the "Sunbeam," not the least were a large stock of Japanese Bantams, about two dozen we think, of a great variety of hues. We will just give those which we know.

1, Pure white, which are very seldom seen. 2, White with what we may call black points. These are commonest, but also, we think, by far the prettiest type. Their marking is something like that of Light Brahmas, save that they have pencilling on the neck hackle. Their bodies are generally white with some dark under-feathering; their primary wing quills half white and half black, their tails chiefly black; the cock's tail feathers-i.e., all the curved feathers, are often laced or edged with white, while the black part of them is covered with a beau-tiful green gloss. The hen's tail is black towards the end, and gradually shaded into white at the base.

3, We have seen one very handsome black pair, or nearly black, for the cock has some rich copper on the saddle and wings such as one sometimes sees in a very dark Dorking; these were from Mrs. Brassey's stock, and have won at the Crystal Palace and many other shows.

4, From the same yard we have seen a small and very pretty pair mottled all over, black and white.

5, We have also seen a cock of the second-named type, but with copper colour across the saddle wings, which we did not much admire.

There is plenty of variety, then, in the colours of the breed to satisfy various fancies, and we suspect that they will be found to breed much more true to form than to feather—at least, if it be true, as we hear, that the above-named black pair have produced some pure white chickens. They have one merit, which we have often remarked upon as appertaining to old-established breeds of Bantams. In contradistinction to those which have been treeds of Bantams. In contradistinction to those which have been produced of late years by the aid of some large breed of fowls, they show no tendency to become too large from overfeeding. This is a great advantage where several breeds are kept, and where there is a general mixture of the young chickens. We have found the hens fair layers and good mothers, though a little over-fussy. The chickens require very constant feeding and nourishing diet for their first three or four weeks, and must have been placed of the product of

have plenty of grit to help them to digest the great quantity of food for their size that they swallow. After that they become extremely hardy, and do not seem to suffer from cold.

For those who require tame and uncommon pets they are admirably suited; they may be easily made as familiar and confident as dogs or cats. The cocks, though bold and aggressive towards larger fowls, are most attentive to their wives, and even brood the chickens at night. They are equally content with a low perch on a clean bed of straw in their houses; indeed a pair of our own had no other house than a Turkey hen's coop. There is no trouble about preparing them for exhibition; they have no leg-feathering like Booted Bantams, that gets broken on gravel or caught in straw; no combless heads to be shaven like Game Bantams, no lacing to grow mossy with age like Sebrights. As they are they may be caught up and put into the exhibition basket, and are by nature so tame as always to do themselves justice in the show

GOOD RESULTS OF UNITING STOCKS-FOOD AND FEEDING.

BEFORE entering, according to promise, upon the question of feeding, it will be well for me to explain the benefit a stock which is to stand the winter derives from having an addition made to the number of its bees, for the perception of this benefit will of course lead to the abandonment of the sickly wasteful plan of burning wherever it is followed, and the substitution for it of driving and uniting. Cottagers, and perhaps others not cottagers, are likely to argue, "Every bee must eat something, therefore the fewer I keep in any hive during the winter the longer will the honey last and the richer shall I be in the spring." Conclusive as this may seem at first it is most illusory, and is not only untrue but very nearly the opposite of the truth. This we may understand by remembering that honey or sugar is consumed by the bees during winter, and converted by them into new forms of matter, really carbonic acid and water, and that during this conversion heat is produced, the heat within certain limits being just in proportion to the amount of honey consumed. The temperature is to stand the winter derives from having an addition made to proportion to the amount of honey consumed. The temperature of the cluster has to be maintained however low that of the surrounding air may be, and if the bees are few in number every one is forced to eat enormously in order that the great demand made

Their carriage is most coxcombical and in exaggeration of the gait of the old-fashioned Bantam. Their combs are single and well developed, of the Dorking shape. The cock's head should be because the quota of heat to be furnished by each is small. In the first case the vital energies of the bees are quickly worn down, and if they live till the spring exhaustion has hold of them and they die as quickly as young can be produced, the stock will be at best but a late swarmer; but with strong lots not only is the demand made upon the individual small, as is also the consumption of food, but the bees live on till late in the succeeding spring, of food, but the bees live on till late in the succeeding spring, their energies being still in reserve when winter is passed. Such hives recoup quickly as the days lengthen, and have often colonised before the little ones of autumn have begun to occupy outside combs. But this only half states the case, for with few bees sufficient heat can only be obtained by each one keeping itself in agitation; and since all muscular exertion must be paid for in food, little loss in activity may actually set were then recorded. lots in activity may actually eat more than populous colonies capable of sustaining temperature in a perfectly quiet and restful state, while the former have frequently the additional disadvantage of having dysentery through over-distention before they can get a cleansing flight. With the idea of returning to this interesting question in the future let me now address myself to

TREDING.—A lady some time since asked me the reason of "white bees" being found upon the floor-board of her hive. I replied at once this indicated great poverty, or, perhaps, imminent starvation; to which she rejoined, "No, that can hardly be, I have only a fortnight since taken from it a splendid super." This false only a forthight since taken from it a splendid super." This faise idea that stocks which have added something to their owner's reputation for bee-mastership by supplying a super cannot require feeding, is so common that it needs exposure. The bees have been prosperous as the super testifies, but as a consequence have been raising brood rapidly. The body of the hive has been filled with it, and all their store has been placed in the upper part of the house but the become in represent it takes all the reserved. house, but the bee-keeper in removing it takes all the resources, while the heavy demand which the vigour of the colony has created only makes its case the more desperate. Always, then, examine hives only makes its case the more desperate. Always, then, examine hives that have given surplus, as these are as likely as others to require assistance. While poor hives will require feeding rich ones may be advantageously employed in building out foundations. Avoiding any interference with combs containing brood or eggs we remove the one best stored, and thus make room for a sheet of foundation in the centre of the hive and feed very gently, for the strongest stocks commonly refuse altogether to work upon artificial midribs unless food is coming in. The coolness of the weather will favour the operation, and soon a perfectly flat sheet of half-formed cells will be produced. This may now be transferred to the posi-tion of outside comb, and the process before described repeated. When the hive is next examined the worked-out sheet deserted by the bees may be taken away, and in the following spring will be of immense service in assisting increasing stocks. No season of the year is so suitable to this work as the present. United hives must be fed-up slowly at first to encourage breeding, and afterwards more rapidly until they possess not less than 20 lbs. of store. Less will carry them through, but hives left rich pay best the following year. Those using moveable combs can form an idea of the wealth of the stock by simple inspection, since each square foot of fully stored comb of the usual thickness of that found in breeding frames would weigh 8 hs. nearly. A total equal to three perfectly filled Woodbury frames would be the smallest with which a stock could be safely left at the close of the breeding season; but no wise bee-keeper would wish to bazish his favourites into a winter of unknown length, with a victualling insufficient for any extraordinary emergency. While poor hives will require feeding, the rich ones may be conveniently used in building-out foundations. When this is started it will not stretch or become irregular, and no time of year is so suitable to this work as the

-The best food is made by boiling loaf sugar with water thus: Put 5 lbs. of loaf sugar into a quart of water and bring to the boil, now add two table-spoonfuls of vinegar and continue the boil, now add two table-spoonfuls of vinegar and continue the boiling a few minutes. The vinegar prevents crystallisation of the sugar, so that it is always ready in the cell of the hive. Loaf sugar costs about $3\frac{1}{2}d$. per ib., but as the weight is increased by the water the syrup costs about $2\frac{1}{2}d$. per ib. Such a year as this extracting and then feeding will produce the most lucrative results. Let me earnestly caution all against feeding with honey, which unless done most judiciously is almost certain to lead to robbing. Plans for feeding will need another communication.— F. Cheshire, Avenue House, Acton.

CROPS IN ESSEX.-Mr. Mechi writes as follows to the Times: -"The threshing and dressing machines are now revealing the sorrowful fact that the deficiency in our corn crop, especithe sortown fact that the dendency in our corn crop, especially on heavy land and even on well-farmed land, is greater than was anticipated, verifying Mr. Caird's and Mr. Scott's estimates of 30 per cent under average. We all expected a better result from the abundance of straw and numerous heads; but the latter are ill filled with very inferior shrunken kernels, and the straw, although bulky, lacks weight and has a dark mildewy colour. Water-loving weeds have had undisturbed possession among the corn crops, for their destruction was randered impossible by the constantly saturated condition of the soil. Root crops are late, and only half a crop; potatoes much diseased. There has been heavy loss by death of lambs, and cattle have done badly on unripened watery grasses. In fact, the absence of sunshine, a low temperature, and excess of rain have prevented healthy development both in farm crops and in fruit."

AUTUMN AMONG THE BEES.

WHAT an autumn! Bees in Somersetshire have been dying by thousands. Not a bee in my apiary would have been alive on this 20th of September if I had not liberally fed them. Most hives for a radius of many miles are gone, yet it surprises one to find that in some oasis, as it were, in the midst of the general desert, honey has not only been stored but even taken in surplus-age—lucky-bee owners, who may make a small fortune next spring and summer by sale of swarms and stocks if there be any

persons sufficiently sanguine to try their luck once more.

Since I last reported the state of my apiary the sugar supplied to my eleven stocks has reached the large amount of 195 lbs., or somewhere between 300 lbs. or 350 lbs. of syrup. I am glad to observe all hives save one (which does not seem to have a very active queen) largely increased in population, of course owing to the stimulus given by the feeding. I observe also that the young bees which have been emerging daily from the cells have already bees which have been emerging daily from the cells have already made large gaps in the syrup stored in the open unsealed combs. This is all well in view of the hoped-for renewal of activity when the ivy season comes on. Then a sufficiency of cells will be free for egg-laying and the storing of pollen during the three weeks it usually lasts, after which a small further supply of syrup will be given them before the hives are finally made up for winter, in order that they may have it at hand in the centre of the hive. This last dole of syrup will be thicker and made more stimulating by the addition of a little vinegar and brandy, the brandy as a stimulant, and the vinegar to prevent crystallisation. Some of my neighbours, bee-keepers too, laugh when I tell them of my outlay. Yet what is it? 4s. 6d. per hive, or even 5s., is worth laying out surely to save a valuable stock of bees which in April next may be worth from £2 2s. upwards. be worth from £2 2s. upwards.

In feeding my bees I found that some of the swarms were at first disposed to make new combs pretty extensively (all worker, as usual, at this time of year), but after a time they preferred to lengthen out the cells even of the outermost combs. This I explain, not as arising out of any foresight of the close of the season, but because the population was for a time continuously decreasing in some hives at a formidable rate every day, and the bees were hardly numerous enough to keep up the necessary heat required for extended comb-building. If I were to feed them now they would doubtless recommence this work, owing to the large in-crease in their numbers to which I have alluded. In some hives with bar frames I tried them with comb foundation, but found them unwilling to use it. I attribute this partly to the same cause—the want of population. In summer—when the hives were full of bees and eager for room, especially when honey was to be had—they took kindly to them. But the year has been altogether against scientific bee management, and yet but for this how few of our stocks would now be in existence?—B. & W.

OUR LETTER BOX.

WEAK DUCKLING (Jane A.).—Put a crystal or two of green vitriol (sulphata of iron) into the bird's drinking water.

(sulphate of iron) into the burd's diriching water.

PRESENVING EGGES (Constant Reader).—Employ eggs quite fresh, paint them with linseed oil, then place them in lime. We generally use a glazed breadpan. The bottom should be covered with slaked lime wetted to a consistence that will allow anything put in it to stand upright. The bottom layers of lime will be 3 inches thick. The eggs are stuck in this small end downwards close together, but not touching. When the bottom layer is full, then a fresh mixture of slaked lime is poured till thick enough for the eggs to stand up in it, and so on till the pan is full. The eggs should be perfectly sound in shell, not cracked or in any way injured, and they must not touch each other. We have had eggs that have been kept twelve months, and then perfectly fit for any culinary purpose. perfectly fit for any culinary purpose.

each other. We have had eggs that have been kept twelve months, and then perfectly fit for any culinary purpose.

CANARY CAGES INFESTED WITH RED MITES (E. W.).—The red mites are very troublesome to keep in check, for they not only infest the cages the birds inhabit, but secrete themselves in every available place and cavrice in the cages and wall, and around the very nails or hooks upon which the cages hang. As to entirely getting rid of them is a matter we have not succeeded in. They will make their appearance in breeding seasons, sometimes more numerous than others, especially during a hot July. This year we have had very few indeed, and we attribute it more to the damp season than otherwise. Cleanliness holds red mites in check, and it is necessary where many birds are kept to have the partitions and cages thoroughly cleaned at least twice a year—spring and autumn. Small cages, which can be readily handed about, may be oftener and more readily attended to; something more than a mere scraping-out of the refuse from the bottoms of the cages. The birds households require occasional cleansing with scalding suds. Red mites accumulate in abundance during the summer months, especially in carcs or partitions where birds are bred. At times clusters of them are to be found in and about the stale nests, and it is necessary that a sharp look-out be kept in disturbing their haunts in the crevices or ends of perches, which may be known by the diminutive grey or mouldy spots thereabouts. If your Canaries ne kept in breeding partitions dress all the likely haunts of the vermin with

turpentine and train oil. It will kill where it reaches the mites. Turpentine itself will very quickly penetrate the slightest crevice; be careful and do not let the birds' feathers become solled with the liquid. Use a small paint brush, and have at hand a cloth to wipe the cage. It will be better to remove the birds whilst operating. Use the liquid to the breeding partitions before taking it down to clean, especially if you have the vermin pretty think about them. It will make short work of the mites and prevent them becoming scattered upon the floor when removing the fronts to cleanse. If your birds are in breeding cages remove them whilst cleaning. Dress the cages with the liquid, and the day after scald and wash them with scap and sods suds. Before placing your birds in clean cages wash them with scap and lukewarm water, rinsing well the scap out of the feathers, and drying with a very soft cloth, finishing the drying of the birds before the fire. It is at the decline of summer when Canaries suffer most from the red mites. At that time the vermin are strong and make sad havoc with the birds, which become weakly through the moulting sickness when the Canaries require all the blood and rest they are being robbed of. Do not use carbolic acid for cleaning your cages. You might destroy the birds and injure the wirework of the cages. Alum solution might be used with beneficial effect to wash the cages with, but when the crevices become dry the vermin will again takes. LUCERNE (6.5s, Ireland).—Lucerne will be found too great a risk of being determed the vermin is the vermin the vermin water.

LUCERNE (G.S., Ireland).—Lucerne will be found too great a risk of being damaged by frost if sown in October; it is best sown in May under the directions as given in this Journal. May 22nd, 1879, page 388. On gravelly soil the land should be broken by the subsoil plough below the depth of ordinary ploughing, otherwise the roots of the plant cannot go down, and will not succeed.

ANTS ABOUT HIVE (F. T., Dalston).—The ants, attracted by your syrup bottle, feed at your expense, but this is the extent of the mischief, for they are powerless to injure the bees. You may by soaking a string in paradin oil and tying a piece round each leg of the hive stand stop their visits pretty effectually; while placing each leg of the stand in a garden pot saucer of water will absolutely checkmate them, but many bees by this plan are likely to get drowned.

to get drowned.

CROPPING LAND (J. W. D.).—If you could find a ready sale for lucerne you map grow it with profit in the following manner:—Plough and press the present oat eddish, sow 3 cwt. Peruvian guano, or 4 cwt. dissolved bones per acre, and three bushels of rye immediately after the presser, then work it in together by the harrows, and in the spring sow 30 fbs. per acre of lucerne seed, and drag or harrow the land sufficient to bury the seed. The crop of lucerne would be ready to cut several times the next year. If there is no sale for lucerne as green fodder, then plough and sow the oat eddish next spring with four bushels of early field peas per acre, drilled 14 inches spart, and sow behind the drill the same dressing as above stated and harrow in. The land will then, if clean, be in good order for a crop of wheat or barley. The next year, if not clean, make an autumn fallow after the peas are off.

From observations taken near London during forty-three years, the average day temperature of the week is 62.8°; and its night temperature 42.4°.

NOTES ON PEACH TREES.

REPARATIONS will now be necessary where very early forcing of the Peach is carried out. The leaves of the trees in the early house will be falling fast, an indication that the pruning and cleaning season will shortly be at hand. This work should always be attended to at the first opportunity after the foliage has fallen. Cleaning the house is an important point, especially if it is infested with mealy bug. Too little importance is often attached

to this operation, and if the woodwork appears clean washing is considered unnecessary. Whether the house requires painting or not is best determined by each cultivator; if it is infested with bug we strongly recommend the application of paraffin, which has already had its properties as a sure killer of that insect advanced in the Journal. For eradicating bug it is certainly preferable to painting. Even if the house should need painting afterwards and bug exists, by all means wash the woodwork and every part of the wire trellis first with pure paraffin. The odour, which may be objectionable, will not remain long, as it is very volatile, and will not injure the most delicate plant. The walls must be washed with spirits of salts diluted with water, care being taken that the mixture does not come in contact with the trees. The trees should next be washed, at least the old wood, with paraffin diluted with water; a safe recipe will be found in Mr. William Taylor's article on page 146. The house and the trees being cleaned, the surface soil must be removed and replaced with fresh soil. If no insects exist the house can be cleaned in the ordinary way. We see no advantage in painting the trees with a mixture of clay, soot, lime, &c., which is frequently done; it is soon washed off when syringing commences, and only settles on the downy skin of the Peach. Soft soap or Gishurst compound will answer the purpose as well as the paint referred to.

It is unnecessary to describe numerous varieties of Peaches, as the best are so well known both for early as well as for general purposes. Lord Napier Nectarine is well spoken of for the early house by those who have fruited it. The old Brugnon Nectarine (syn. Red Roman) is a good reliable variety for early work; it stands forcing well. The fruit is of fair size and good colour when ripe. It does not appear to be grown so much as it deserves.

LIFTING PEACH TREES.—Concerning this there exists a variety of opinions; nevertheless the one we advocate will, if carried out according to our instructions, reward the cultivator with a full crop of fruit from his trees the following year, provided the wood is well ripened and the buds plump. When to all appearance the trees are in good condition it becomes necessary at times to lift them for the purpose of renovating the borders and to check overluxuriance. Lifting is not only beneficial for the purpose of making the trees more fruitful, but it induces the production of healthy fibrous roots. When transplanted at the proper season the trees start freely into growth when required to do so, and give no indications of having suffered

by the operation they have undergone. We prefer lifting Peach trees in the autumn. It would be difficult to set a fixed time, as that entirely depends upon the time the wood becomes sufficiently ripe and the buds matured; this work should be done, however, at least a month before the leaves commence falling. If lifted carefully the trees will not shed their leaves prematurely. The trees soon commence producing roots if they are well syringed and the house is kept close for a few days: under this treatment the trees start earlier into growth than when spring-lifting is resorted Trees lifted in a dormant state have not the chance to produce roots and become partially established before they are to be started into growth. We have frequently seen trees lifted in a dormant state showing signs of injury in the spring; in many cases the flowers do not properly develope and are unfit for perfect fertilisation, and the fruit either falls in a small state or before the stoning period is over, and in some instances after being started the flower buds fall. We do not wish to say that trees under the latter mode of lifting always present such results as we have described, because it depends to a great extent upon the time the trees have remained undisturbed at the root, and the condition of health the tree is in at the time of lifting. If the trees are old and declining in health, or the roots of younger trees are long and fibreless, they cannot make that rapid progress that they would do under the early-lifting system. They not only make abundance of fresh rootlets before the foliage falls, but are well able to produce strong and thoroughly developed blooms and to carry a crop of fine fruits. We have perceived a marked difference between trees of the same size and same variety, the one lifted in a dormant state and the other when carrying healthy foliage, the latter ripening the fruit fully a fortnight earlier than the former. We have already done all the lifting necessary in our Peach houses, and find the earliest-moved trees have made a quantity of fresh roots.

SOIL AND BORDERS .- In case the borders require to be renewed it will be necessary to select some good fibry loam of rather a strong texture. Too frequently do we see soil used for Peaches and Nectarines of a light and sandy nature, which encourages gross useless wood that will neither ripen nor bear fruit satisfactorily. In this kind of soil the roots ramble away through the border with great freedom, and require to be much more frequently lifted, and the trees are more susceptible to the attacks of red spider and mildew than when grown in soil of a heavier nature. Experience teaches us that better roots and fruit will be produced by trees planted in rather heavy soil. It is sometimes difficult to obtain suitable soil for Peach borders, especially in the immediate vicinity of large towns. This can to a large extent be remedied by adding clay in proportion as the loam is light, which is in the best possible condition for incorporating with soil if previously exposed to frost until it has fallen to pieces, and then stored in readiness. If, on the other hand, the soil is too heavy, lime rubbish, charcoal, and wood ashes can be mixed with it. Should the loam be such as Peaches delight in, no additions will be necessary. It is, in our opinion, a serious mistake to add large quantities of manure to the soil for Peaches and

NO. 1618.-VOL. LXIL, OLD SERIES.

NO. 966.-VOL. XXXVII., NEW SERIES

Nectarines. Bones are preferable, but even these are unnecessary. Manure encourages the tree to make coarse sappy wood. Further, we have concluded that manure coming in direct contact with the roots causes to a large extent the production of suckers.

Old trees that have been established in borders for a number of years and have borne good or moderate crops of fruit will deteriorate when the border does not contain that nourishment for the support of the trees it formerly did. Each year the trees have less food to consume, except what may be given in the form of top-dressings or liquid manure, which in the end prove insufficient. The old trees become less vigorous, declining each year in health, and at last have to be pulled out. To save this rooting-out, at the first symptoms of decline the roots should be examined and the border renewed; the trees will, if not too far gone, quickly recover, and produce good crops for several years afterwards. If old trees become thoroughly injured through careless treatment and they commence to decay near the pith no after treatment will restore them. This can be perceived as soon as the trees commence growth by the silvery cast the foliage presents, and in many instances the first leaves turn yellow and fall off. Replanting with fresh trees is then the only course that can be adopted.

Turning again to Peach borders, we cannot see the use of such deep and large borders as are generally made. The border, of course, must depend entirely upon the size of the trellis the trees have to cover. Making large borders inside and out is an unnecessary expense and trouble. If deemed prudent to have the roots inside there is in most cases sufficient room, and often more than is needed, without making large borders outside as well. We find borders 18 inches deep ample whether inside or out, and rather than make large borders we would lift the trees periodically and renew small borders when the soil becomes exhausted.—W. BARDNEY.

HARDY PERENNIALS.

WHATEVER have been the failures, and they have been many this season in the flower garden, the established hardy perennial plants may be pointed to as having been eminently successful. True, they are a little behind their usual time of flowering, but when they do come they are just as bright and equally as floriferous as in an ordinary season; in fact, when contrasted with the rest of the flower garden they look brighter and more beautiful than ever they did, and I believe they have gained substantial ground in the estimation of the public. For those who contemplate growing these interesting plants now is a good time to make preparations for a beginning; and as there is, if success is to be secured, a great deal to be thought of and more to be done, I would advise that there be no delay, at least in the thinking part of the business; and as many people will feel a relief in getting rid of their unsatisfactory summer bedding, there need not be much hesitation about clearing it out of the way at once, and so get rid of an eyesore and commence with fresh interest and new ideas. But there must be no half-and-half sort of work. Perennial plants with a few exceptions do not look well in formal beds. It will not do to merely clear away Alternantheras, &c., and plant a Michaelmas Daisy or an Evening Primrose in their places. Keep some of the formal beds if you will; if they look dingy and unsatisfactory this year, they have looked bright and have had many admirers before, although there is no doubt we have had too much of them both in point of taste and convenience. There is no objection to the perennials taking the place in our hearts which the ephemeral carpet-bedders have for a time monopolised, but they must not be substituted for them in the middle of the lawn; their general position requires to be de-termined by a true artist, so that they may add to the beauty of the landscape, instead of being a blot on it as many of the formal beds undoubtedly are. It is more than probable that our taste would improve in such matters if we were favoured with brighter skies and warmer air; but in the general dulness and the almost superabundance of foliage surrounding our country houses a bit of bright colour is cheering, and very often general effect is sacrificed for a local whim.

The site being determined on for a patch of miscellaneous hardy perennials it must have a background of shrubs, and, indeed, the spot likely to be selected is almost certain to have shrubs on one side of it if the grounds have been tastefully planned. Straight outlines should, I think, be avoided as much as possible, although in my own case they are straight on both sides; but I have the advantage of a good belt of

shrubs, mostly Rhododendrons of informal growth, at the back, and the front has pillars and arches covered with climbers not too closely kept, which answer the double purpose of joining the borders to a strictly geometrical garden and breaking the monotony of the straight lines. I should not of my own choice select this spot for hardy perennials, but it has its advantages, not the least of which is its comparative security from rough winds.

Soil and drainage are important items in growing these as well as all other plants. It is better, I think, to err rather on the side of lightness and porosity than the reverse, and it should not be over-rich with vegetable matter. Common garden soil will answer the purpose very well if it is moderately light; a good dose of lime will improve it if it is so rich in humus as to make slugs and worms troublesome. For those who have the choice there is nothing better than a good proportion of peat; and as I could have it for the carting, I took advantage of this and put a good spit of peat on the top of the border, and then dug it over, bringing the surface of the natural soil mostly to the top. Slugs and snails are the worst enemies of many of the choice herbaceous plants, and peat does not harbour them. Where peat is not easy to procure a quantity of gritty material should be used. The majority of the plants delight in soil which is not heavy; the few exceptions can have loamy soil added at the time of planting, and hardly any of them will survive in a soil which does not admit the water to pass freely through it. The ground being prepared, October is a very good time to plant some of the hardier species if they can be obtained in a suitable condition, they will then become established and make a little root growth before winter. Those which are puny or of doubtful hardiness had better be kept in pots, where they can be sheltered if necessary till spring. Where there are established plants to be divided, and which readily increase by division, autumn is the best time for many of them, and the length and habit of the herbaceous stems is a great guide for placing them in suitable positions. Many of them, as Aconitum autumnale and Veronica virginica, are of tall and slender growth and take but little lateral room; others are wide-spreading, as the Japanese Anemones, Funkias, and some of the Enotheras, and will bear looking at all round; others, again, though growing rather tall when established need to be close to the eye for due appreciation, as Tricvrtis hirta.

All these and many other points press themselves on our notice when re-arranging plants in autumn, but some of them are liable to slip our memory during the winter. It is a difficult matter for even a practised hand to arrange a perennial border right off, so that the ground may be fairly covered without the plants being too much in lines or in other ways too stiff-looking. The known habit of the plant is then a great assistance in this part of the work, and every advantage chould be taken in the plant is the part of the work, and every advantage should be taken of it. I must insist on perennial borders being strictly confined to perennials, not necessarily to herbaceous plants, but shrubs and half-hardy plants must be excluded. Those who recommend such barbarous mixtures cannot know much of the inexhaustible beauties of a collection of hardy If you complain of the flowers going off and perennials. leaving blank spaces, have the early-flowering plants in one part of your garden and the late-flowering plants in another, then if you only love them for their gay colours you need not visit them when these are absent.

There is one difficulty which I cannot dispose of satisfactorily with regard to these plants. I don't like to see hundreds of conspicuous labels, and yet I cannot do without them. I may know every plant by sight or position myself, but there are others who do not. So far I have used merely a piece of round stick with just enough of the bark scraped off to give room for the name, but even this is objectionable.

—WILLIAM TAYLOR.

COMBINED CULTURE OF GRAPES AND PLANTS.

I HAVE thoroughly proved the fallacy of the assertion that Grapes and plants cannot be grown in the same house. I have cut, or shall cut, fifty bunches from one Vine in a small double span house—i.e., a house 25 by 16, in which I grow Zonal Pelargoniums, Begonias, and twenty other kinds of plants, and from four Vines planted only last year in a stove to occupy only one side of the house I have, or shall this year, gather about forty to forty-five bunches; yet I had no fire heat from May 1st to July 17th, and then only for a few days, again in August and now at nights; but as the house catches every ray

of light and sun and is never shaded the temperature often goes up to 80° in the daytime, and it gives wonderful colour and blooming qualities to plants. I fear, however, this is a twice-told statement. I may add that as I hear it is generally a bad season for Begonia seed, I am willing to supply seed at 2s. 6d. and 1s. a packet to those who apply before the middle of October. I am obliged to make a charge, as already, owing to notes about Strawberries, I have had fifteen applications for runners, besides promises made to intimate friends living near. The seed hybridised from the choicest sorts—i.c., Sedeni, Vesuvius, Freebelli, Miniata, Kallista, Stella, besides from seedlings of my own selected from a great number. I limit myself to 150 packets.—C. P. PEACH.

THE PHLOX OF THE FLORIST.

THE present season, notable as it has been for the many failures with most out-of-door flowers, has been one especially favourable to the growth of the Phlox of the florist. Our selection of these has been in fine condition for weeks past, and the plants will continue with good weather in beauty for some weeks longer. I do not remember ever seeing Phloxes do better than those above alluded to, and the cultivation they have received was of the simplest character. It is just one year since the larger plants were planted, the newer and some of the older varieties on trial being planted in spring. The way these plants were managed was as follows:—The portion of the broad border they now occupy was cropped last summer with Peas and Cauliflowers, and when these were cleared off a mixture of manure from the stables and cowhouses was carted on and the ground turned over 30 inches deep, working the manure in as the work was proceeded with. In October some plants struck from cuttings eighteen months previously were lifted, the strongest divided and replanted in the border prepared as above. The stems were not cut down until they had decayed naturally, and to do this much of the strength displayed by the plants this season may reasonably be attributed. These old stems, worthless in one sense, as having bloomed at the same time, acted a very beneficial part in establishing the plants in their quarters before winter, and in producing stronger buds ready to start without any check in spring. When well started at the latter season the young growths were thinned out to from three to five of the strongest; numbers quite sufficient to ensure a display without deteriorating from the size of spike and quality of bloom from overcrowding. At the time of thinning the ground was also pointed over, and a further stock of young plants placed out, some from offsets and some from plants in pots; a little later on strong stakes, and 3 feet above ground, were placed to the plants, at the same time carrying a strand of matting loosely round each plant. Had the season been an ordinary one a surfacing of manure would have been given them at this time.

The routine work for the remainder of the season consists in tying loosely the growing shoots, and at the last if too crowded the weakest of the shoots may require cutting out. If any heads or spikes are wanted for exhibiting shading must be resorted to in order to keep the colours pure and the heads entire. Rain and sunshine, or even a dewy night followed by a sunny day, causes unprotected flowers to fade early, light shades to become dirty-looking, and darker shades to look streaky and wanting in purity of colour. There is no better mode of shading than extemporising glass covers with old sashes, but newspapers or calico may be made the most of where glass cannot be obtained. The plants can be lifted and where glass cannot be obtained. The plants can be litted and placed under glass, without any damage being done to either plant or flower provided that plenty of water is supplied. The Phlox is a most accommodating plant. In spring I had some offsets from a gardener. By the time these offsets were planted in the piece of ground beside the others they were looking most unsatisfactory, but notwithstanding I have some excellent heads of bloom developing just now on most of these. It proves to be a ready means of obtaining the earlyflowering section at the same time as the late varieties; and as the lighter-coloured varieties in the early-flowering section are superior to those of the same shades in the late varieties this is a matter of some importance. The same end can be gained by striking cuttings in spring and growing and flowering them in pots, but this necessitates an extra amount of trouble.

Phlox cuttings can be struck successfully at any season of the year; the main point to be borne in mind is not to subject them to a heat sufficient to cause the shoots to draw up spindly.

The spring season is the only time heat is required in order to lights the soil was worked away gradually with a fork, and all

induce them to root freely. Plants in their second season produce the finest heads of bloom. After the third year's growth the plants will require dividing as previously directed. The names of varieties which are the finest at present in flower here are Chanzy, Princess Louise, Bryan Wynne, Coccinea, Souvenir de Berryer, David Syme, Andrew Borrowman, Madame Andry, Lothair, Mons. C. Turner, Roi des Blanches, Thomas Ormiston, White Lady, Lady Middleton, John Baillie, Lilacina, Mrs. Hunter, and Lady Napier. Other desirable varieties are Mrs. Laing, Amabilis, Madame Moisset, Miss Macrae, D. P. Laird, Duchess of Athole, Perfection, Purple Emperor, and Mrs. Doig.

The directions given above have been intended for those desirous to obtain spikes for exhibition, but Phloxes are amongst the best late-flowering border plants in cultivation. In borders which have not been trenched for a number of years it is necessary to add a mixture of dung and loam to the soil. There is yet another use they may with great advantage be put to, and that is for the decoration of large conservatories. These may for this purpose be either grown from offsets or from cuttings in their second year. About five shoots to a plant are sufficient, and all sprayey growths must be removed from the plants. Pots 9 inches in diameter are a good size to grow them in, and a mixture of three parts loam to one of decayed manure a good soil. Liquid manure must be supplied them when the pots become filled with roots.—R. P. Brotherston.

DEFECTIVE VINE BORDERS.

THE season of 1879 will long be remembered for deficiently coloured Grapes, perfect colour being quite the exception amongst black varieties this year. Although the bunches and berries may be large, if colour is wanting more than half their attraction is absent, and although they may be very well flavoured they will fail to obtain that approbation at table which most gardeners desire. Want of colour in Grapes may, I think, be attributed to many causes. Sometimes the gardener may be to blame, very often not. No man would produce badly coloured fruit intentionally. Still there are mistakes in practice. Air is generally only admitted to vineries in any quantity when the sun is bright. There has been little of the latter this summer, and it is just possible that in many vineries where the fruit has not coloured ventilation may not have been efficiently attended to at the time when it was most required. If Grapes need fresh air to assist in colouring them in hot sunny weather, they need it equally as much in sunless weather. The best coloured Grapes we ever had was in a year noted for its want of sun, and the worst for colour we ever had was in an unusually bright season. In both cases air was admitted liberally, and in the dull season after colouring was commenced the ventilators were opened just as freely as if the sun had been shining.

I am of opinion that a deficiency of sun heat will seldom cause Grapes to fail in colouring, providing the atmosphere of the house is kept in a proper state to assist colouring during that period. Heavy cropping must be avoided, and the Vines should be in a fairly robust state of health, or the cause of not colouring must be looked for elsewhere. I am strongly inclined to think that imperfect borders have a great influence in causing Grapes to colour badly. In many instances I believe it is the sole cause, and now that we have seen the bottom of the border in which our Vines were growing, which failed to colour their fruit, we fully believe it was here the mischief rested. It is very well to give Vines plenty of water and to have abundance of roots in a rich surface dressing, but if the foundation of the border is not right deficient colour will be the result until this has been rectified.

We have secured fair crops of Grapes out of one of the vineries here for several years, but they have never been so vigorous as we desire; fresh top-dressings in which plenty of roots formed appeared to put a little extra life in them, but still they were backward and not much to be depended upon. At last we resolved to look to the border, and found it in as bad a state as could be conceived; drainage there appeared to be none, and the soil 2 feet or more from the surface was a barren stiff mass. This was entirely removed to about the depth of 3 feet, stones and ashes were placed in as drainage, and the whole filled up with loam mixed with limestone, road scrapings, and a good sprinkling of cowdung. In removing the soil it was not taken out indiscriminately, but after digging a trench along the front about 10 feet from the front lights the soil was worked away gradually with a fork, and all

the roots were laid back and preserved, but the few which were in the old soil were so destitute of fibres that most of them were cut back to 2 or 3 feet from the base of the stem. From these cuts many young rootlets will be emitted that will be of much more service to the Vines in good soil than the old ones were in bad. Perhaps it ought to be understood that these Vines were not wholly lifted, as a strip along the front of the house about 18 inches in width where the soil was sweeter and contained many roots was left without doing much to it. This will keep the Vines from sustaining any severe injury until the young roots have penetrated the new soil, and after that the old soil will be harmless. I may also state that these Vines were lately relieved of their fruit but still retain their foliage, and we hope that this will induce the young roots to find their way into the new soil before the winter, when they will be ready to help the Vines into growth next year.

For the above reasons we are of opinion the present is the best of all times to make alterations of this kind, and providing the soil was not entirely removed from the roots, as above indicated, we would just be as much inclined to treat Vines on which the fruit was hanging as those without it. Much cow or horse dung is not to be recommended for Vine borders as a rule, but I am of opinion that a little is necessary in renewing borders to give the old Vines a stimulant.—M.

CARNATIONS AND PICOTEES .- No. 9.

As all plants will or should be layered by this time the only attendance they require will be to water the crowns from a rose when the soil is dry, otherwise the young roots of the layers near the surface are liable to suffer injury. I have generally noticed that plants which have to make second roots are frequently affected by canker. Prepare a compost for planting the layers in when rooted; that which I employ for this purpose is formed of three parts maiden soil—the top spit from a pasture will do—one part of burnt refuse, with a small quantity of leaf soil added. If the soil is very strong I add a quantity of sand, not otherwise. For single plants or two small layers I employ pots 3 inches in diameter; $3\frac{1}{2}$ -inch pots being suitable for two large or three small layers. I run the soil through a half-inch riddle, carefully picking out all earthworms and wireworms.

Potting may be commenced at once, if done earlier it sometimes happens that the weather proves mild and the plants become root-bound. It is important that the drainage is good, placing a little fibre or a few half-decayed leaves over it in order to prevent the soil from running amongst the crocks. Clean the layers from all decayed foliage, making the cut when separated from the parent plant at the first joint below where the cut has been made when layering. If cut at a joint more roots will be formed during the winter months. Plant the layers near the inside edge of the pots, as the sooner the roots of the plants reach the side of the pot the better. Be sure to wash the pots and crocks before using them, and any new pots before being used should be well soaked in water. After being potted a gentle watering with a fine rose will be required, and then the plants may be placed in a frame facing east or west, closing the frame for a few days, after which time the plants may be left exposed, only protecting them from drenching rains.

At the end of October or first week in November they should be placed in their winter quarters. For this purpose I find frames about 5 or 6 feet wide with lights 3 feet to 3 feet 6 inches in width the best; the frames placed on a bed of ashes. Be careful when placing the pots in the frame to examine them carefully, as it will frequently happen that the slugs will make the hole in the bottom of the pot a residence. As many of the seed-pods will not be ripe when the layers are taken off it will be well to leave a shoot on the plants bearing pods to keep the sap moving. As the seed-pods ripen they should each one be rolled up in a piece of soft paper, otherwise the pods when full of seed are liable to burst, in which case the seed would become mixed. To show how necessary it is to keep a registry of the crosses, I may say that some few years ago I hybridised some plants for a friend of mine. Two very fine varieties bore a number of pods. The seed was sown in the usual way; there was a good stock of plants, but not one good variety amongst them. Had this occurred in mixed seed it would have been impossible to tell what variety had produced them; but knowing it by the registry will prevent me from using these varieties as seed-bearers again. Loosen

the stems of all the seed-bearing plants, remove the petals a few at a time, and pull off one of the segments of the calyx so that the wet may not lodge there.

Plants in Beds.—Layering amongst these ought to be completed; any stools which have not been layered, if intended to stand for another year should have the old leaves trimmed off the shoots as if for layering, pegged down, and covered with soil, pressing it firmly amongst the shoots. It is a good practice to give the plants a watering with lime water, which will generally expel the worms from the roots. Plants or stools can be removed now, whilst beds of new layers can be planted where required. The best plan is to plant them 18 inches from row to row, and 12 inches apart in the rows; in this manner two rows form a bed say 3 feet 6 inches wide, which is very convenient for weeding, watering, layering, &c.

Seedlings.—Potting should be finished at once. Place them in pots the same as layers, wintering them in frames in the usual way. Where seedlings are intended to be planted in the open a crop of Potatoes or Carrots should have been grown, as they bring away with them the Carnation's great enemy the wireworm. If the soil has been manured it will not be necessary to manure it again, but dig it deeply, breaking the soil fine, and if light adding to it road-scrapings or anything of that kind; whilst if strong some burnt rubbish may be added. Be particular in looking out for slugs, as they are very destructive at this time both amongst seedlings and layers whem planted in the ground; they eat out the pith where the cut has been made. Any plants which may have lost their centres should be examined carefully for the rose-borer, which in some situations is very destructive, boring as they do right down the centre of the plant. Destroy them whenever found.—George Rudd.

THE ASSOCIATION HORTICOLE LYONNAISE.

HAVING been frequently invited to act as a member of the Jury at the great autumn Show of the Association Horticole Lyonnaise at Lyons, I this year accepted the invitation, and was much pleased with what I saw. The Exhibition took place on the 11th, 12th, 18th, 14th, and 15th September in the Place Maraud, one of the public squares on the banks of the Rhone, and was partly under canvas and partly in the open air, the square being enclosed by a cheap fence for the occasion. One thing struck me on entering the show ground—namely, the small expenses incurred in producing the exhibits and in the getting-up of the Show. It is true that many of the plants were small in comparison with what we see at our English shows, but I should hardly like to say that there was less skill displayed in their cultivation; for although they did not represent extraordinary horticulture as many of our exhibits do, they were in every way satisfactory as examples of ordinary horticulture. There were quantities of Palms, Caladiums, Coleus, Fuchsias, Geraniums, and other greenhouse plants, not large but unexceptional in point of quality; also Dahlias, Phloxes, Carnations, and Pyrethrums among out-of-door plants, and indeed almost every flower of the season that is recognised and grown in English gardens. There were also fine collections of Conifers, and Hollies were better than we had ever before seen them in France.

Among fruits the Pears were numerous and fine, the Apples less numerous and poor. I have always thought that France is a long way behind us in the Apples, and this exhibition confirmed that opinion. There were two seedling Pears exhibited which so far as one could judge by appearances seemed fruit of great promise; the one named Notaire Lepin, something of the shape of Beurré Diel, said to be in season from January to March, and the other Notaire Bonnafond, nearer in character to Louise Bonne of Jersey, ripening from December to February. There were also other novelties among Pears, but such were of less striking appearance. One seedling Peach, Victoria Thorine, which might be compared to a very fine Gallande, looked very tempting. The collections of vegetables and salads were of the very first order.

Cut specimens of hardy flowering shrubs and herbaceous plants were also numerous and exceedingly interesting from the tasteful manner in which they were arranged. The cut Roses were a leading feature of the Show, and I was much pleased with the display. It would serve no useful purpose that I can see to compare their exhibits under this head with ours; it would be like comparing prize cattle with cattle fed for domestic use. As before said, they go in for ordinary, we for extraordinary horticulture, but there is as much difference in point of skill in cultivation and taste in the arrangement of the competing collections with them as with us. One small collection of Roses occupying a semicircular raised stage was composed of good ordinary flowers such as any industrious and skilf cultivator could produce without straining or lavish expenditure, and they were moreover arranged with exquisite taste. I looked again and again with intense satisfaction on this group. The other exhibits were, however, equally worthy of inspection, some containing a greater

number of flowers of equal merit. The whole were out with long stalks, the expanded flowers being surrounded with a profusion of buds, and now sheltering behind, now resting among, and anon rising above the beautiful masses of foliage. Although the flowers were not nearly so large as those met with at our flower shows, there was the charm of Nature about them which vividly impressed me. All the leading varieties were abundantly represented from the tiny Lawrenceana and Polyantha (the latter with too many buds on a stem to be counted), to the huge Paul Neyron and the single Rugosa rubra, with its large round petals and bright scarlet heps. The polyantha paquerette is indeed a tiny gem, the flowers not larger than those of the White Banksian, which indeed it resembles, and is perhaps even more exquisite in outline and arrangement of the petals. Tea-scented Roses were abundant and of excellent quality. There were also numerous seedlings, but these were not named. Mons. Levet showed five seedlings; No. 1 a good copper-coloured Rose, and No. 2 a fawn-coloured variety, both tea-scented, were in my opinion novel in colour and of geod quality. M. Lacharme showed a seedling between Victor Verdier and Sombreuil, something in the way of Capitaine Christy, which struck me as good, sufficiently distinct, and of vigorous habit. M. Schwartz produced three seedlings all Hybrid Perpetuals. One, apparently the best of the three, was in the way of Elise Boëlle; the next in order of merit bearing some resemblance to Antoine Ducher; and the third a pretty pale pink variety of very exact form. There was also a prettily tinted tea-scented seedling, not over-double, from MM. Rambaux and Dubreuil Geure, marked No. 1.

The tent in which the Roses were shown was better ventilated than our tents generally are, in fact it was open on one side; and I thought this an improvement, for the flowers remained fresh for a long time, and the odour was not the odour of a stuffy tent, but the natural odour of a Rose garden, and as we stood admiring we were continually refreshed by the breezes from the rippling Rhone. The banquet in the evening of the first day of the Show was a very spirited meeting, and of our many visits to Lyons this one left on us the strongest impression of the industry, ingenuity, and skill of the horticulturists of that part of France.—WILLIAM PAUL, Paul's Nursery, Waltham Cross.

WINTERING DAHLIA TUBERS.

LAST winter our Dahlia tubers were covered up very carefully on account of the severe weather, and, with the exception of one tuber, the entire stock was lost. It was not the care taken to have them perfectly secure that caused the loss, but oversight with regard to the covering. As a preservative as much the soil as adheres to the tubers when lifted is allowed to remain on them, merely allowing it to become dry before covering them up. The material used for covering is straw, and though I have no doubt now that the Dahlias would have been safe enough with the amount at first placed over them, as seed Potatoes in the same shed wintered safely, still to make sure a very thick covering of straw was added. By this no doubt the Dahlias were destroyed, for when examining the stock at the end of January or beginning of February a white mould was found enveloping them, caused by the added straw being slightly damp; at least this is the only apparent reason. Nothing better than a covering of dry straw can be had for preserving the tubers, and we send this warning for others to ascertain that the straw is dry, more particularly when it is placed thickly over them. Cocoa-nut-fibre refuse where it can be easily procured is a good material for packing and preserving them in. Of course it is necessary to lift the tubers before frost injures them, and to dry them somewhat before placing in their winter quarters, otherwise no amount of after care will preserve the stock.—R. P. BROTHERSTON.

More Food at Less Cost.—A manual on this subject has been published by Ellis Lever of London and Manchester. The author is Mr. Leo Hartley Grindon, and the subject was suggested by Mr. Gladstone in his speech delivered at Hawarden on August 28th. The pamphlet is admirably written throughout, and has reference to cottage and window gardening; vegetable and animal food, its cost and production at home and abroad; farms and cereal crops, Covent Garden and Columbia Markets, sewage, cookery, and co-operative farming. The benefits of cottage gardening are thus referred to:—"Working men who are encouraged to practise horticulture for their own sakes and own advantage, both as to pleasure and money profit, do most certainly acquire reputable and exemplary habits such as no other twofold occupation—business and pleasure going together—can ever stimulate and develope so well. They learn the unspeakable value of what many people call by the shameful name of 'idle time.' Spare

pence are laid out in seeds and plants instead of unnecessary drink; and a love of simple and healthy recreation with the spade and rake displaces all care for the hurtful and often brutalising sports which are so frequently resorted to, not so much from deliberate choice or natural inclination as through want of help towards a rational pastime. For sports, indeed, of a mean and brutalising character the gardener has never either leisure or disposition. Explain the matter in any way you like, the fact remains that the appearance before the magistrates of a working gardener—one who gardens for himself and in his own right—is well known to be quite a phenomenon." And on the subject of flowers in hospitals and infirmaries we cite the following :- "Give the poor occupants of these weary sick beds bread and medicine by all means, benedictions too if inclined that way, but give them some flowers as well. The surest way to induce the poor to believe that they have a 'Father in Heaven' is to let them discover in the first place that they have brothers and sisters upon earth. That 'flower missions' to hospitals have for some time been zealously and successfully at work we are well aware; but ask of those who superintend and manage, and they will tell you that their want is not opportunity to carry out their pious designs but more flowers wherewith to effectuate them." The manual is well worth reading.

MESSRS. SUTTONS' POTATOES.

I AM not aware if it is generally known, but it certainly should be, that there are three varieties of Potatoes bearing Messrs. Suttons' name that are freer from disease than any other varieties that I am acquainted with—viz., Suttons' Redskin Flourball, Suttons' Magnum Bonum, and Suttons' Woodstock Kidney. Perhaps there never was a better season than this for indicating the weak points of Potatoes. Unfortunately the disease has been prevalent in all parts of the country, the result being that many that were considered good varieties are nearly lost. This has been the case here, and according to the papers elsewhere also; therefore those varieties which have suffered the least deserve to be noted. On this account too much cannot be said in favour of the three named above, as they are all nearly disease-proof. I am judging them on their own merits, as well as comparing them with over five dozen other varieties grown here this season.

About the middle of June we found many diseased tubers amongst the early kidneys. By the middle of July many varieties were badly spotted on the leaves, and as some of the early varieties were beginning to indicate ripeness in the haulm many of them were taken up with the hope of saving them, and some very fine tubers were taken up without spot or blemish; but although they were dried and stored in a suitable place many rotted when they appeared perfectly safe. As is generally the case the best went first; notably Red Emperor, International Kidney, Blanchard, and many others of equally fine appearance, and all have suffered more or less in the ground or out, but the three under notice were perfectly sound in both places. Redskin Flourball probably may become diseased in some localities, but it is not so here in the garden nor in a field close by, where some fine sound tubers were lifted the

Magnum Bonum is well known to be free from disease in nearly all places, and in this respect it has surpassed the Scotch Champion here, which is said to be wholly free from disease. Many of the American varieties are said to be wonderfully free from disease in their general character, but none of them have resisted it so well as Magnum Bonum; and the same remarks apply to Woodstock Kidney, which is of the greatest importance, as it is such a handsome variety, quite equalling in this respect International Kidney, and when boiled it is much superior to that. In future these three Potatoes will be largely grown here, as they are good in quality, heavy croppers, and last, but not least, disease-resisting.—A KITCHEN GARDENER.

ROSE CATALOGUES.

THE autumnal flight of these is just setting in. They are more interesting I think every year, and certainly deserve more study than they mostly meet with. The yearly preparation must be a work of considerable labour. It is told by, not of, a very famous catalogue maker—note the distinction for fear he should charge me with libel—that about this period the involuntary author retires from public life; a white glove is on the knocker, and until the printer is done with there is only one

answer to all inquirers, He is "as well as can be expected!" I have just had the benefit of a catalogue from across the water. It is interesting to notice the difference. The blending of business with information is very graceful. And first of all there is a charming little bit of true homage, "Vivat Regina!" It is quite the echo of our National Rose Society's motto, "What elegance of form, what finesse of colour, what (I fear not now always) delightfulness of odour!" "The Rose is of all the ages, of all the ranks. She queens it in all the gardens, she forces us to love her, she chooses to be loved, and she is loved with love indeed; her admirers are the most constant of all the lovers of horticulture!" Then follows a little bit of advice to M.M. the amateurs. I do know that I quite agree with it, at least in order to carry it out Roses should be few or gardeners many. As a protection against the frost it is suggested that the earth should be heaped up high round each individual Rose, and an earth bank made the protector. The subject is important in the likelihood of a hard winter. I should rather say, Manure well, and then add as much fern or such like as you choose on the top of it. November is shown to be the month of months for transplanting; and if this be not done till spring frequent waterings are stated to be probably required. I notice amongst waterings are stated to be probably required. I notice amongst the names a growing tendency, very advisedly, to give also the synonyms—e.g., Jaune de Fortune, synonym Beauté de Glazenwood. It is to be hoped this will help to keep the catalogues clearer. But still, O Belle France! do not you think you could shorten? Two names ought to be enough for any Rose, and one for preference, not as now those endless souvenirs. The cover, as might be expected, is of the most recherche Rose, and if this meets the eye of Mons. L. B. Guillot fils, I beg to make him my profound acknowledgments.—A. C.

THE LONDON PARKS. VICTORIA PARK.

FOR some years past the different styles of bedding have been here most admirably carried out, and the park has acquired, under the able management of Mr. McIntyre, considerable reputation in the horticultural world. The same care and taste are evident in the arrangements and designs this year, but unfortunately the effects of the dull wet season are only too apparent in the stunted growth and flowerless condition of many plants, thus giving a dreary unfinished appearance to beds that are usually so bright. This is by no means surprising, especially when we consider that the position of this park is one that even in the most favourable weather is far from being well adapted to the health of plants, surrounded as it is by an atmosphere loaded with poisonous vapours from numerous factories. But notwithstanding these disadvantages several beds were noteworthy for their elegance and brightness, and this was particularly the case in the principal flower garden. Most of the long beds at the back were planted with Pelargoniums and edged with Echeverias, while those in front were occupied with the various plants employed in carpet designs. One long bed of Centaurea ragusina and Verbena venosa was especially attractive, and another equally good had a centre of Ageratums margined with Centaureas, the colours in both instances forming a most agreeable contrast. Of the front beds one near the outer side was very pretty; it was edged with two rows of Echeverias, the groundwork being composed of Mentha Pulegium gibral-tarica; in the centre a portion was raised, also edged with Echeverias; and on this was a design in Alternantheras and Pyrethrums, relieved by a few single specimens of Echeveria metallica, Sempervivums, &c. Near the above is a long herbaceous border, in which the showy Tritoma Uvaria is largely planted, intermixed with Helianthuses, Phloxes, Dahlias, Veronicas, Tagetes, Tropscolums, Pelargoniums, &c., the general effect being bright and pleasing, as indeed this form of bedding is almost invariably.

Of the carpet designs in the sheltered portion of the park devoted to them the most noticeable were the following:—A circle edged with Echeverias, the ground of Herniaria glabra, in which was a central star of Mesembryanthemum cordifolium variegatum, Alternanthera amœna, and Golden Feverfew. A six-lobed bed was margined with Pyrethrum, and contained small designs of Alternanthera amœna and Echeverias in a ground of Mentha. The long scroll bed had a margin of Echeverias, a ground of Mentha, and a series of small raised panels of Alternanthera amœna, A. versicolor, and A. paronychioides major, edged with Echeverias. Pretty, but the designs, we think, were too small. The subtropical plants

were generally rather weak and stunted, although one bed of Wigandia caracasana edged with Amaranthus melancholicus ruber was well filled, and the plants moderately vigorous. Ficuses, Cannas, and Ricinuses were also extensively planted, and some of the latter were in fair condition.

REGENT'S PARK.

Here we also found the ill effects of bad weather paramount, in this case aggravated by the shade of the trees which constitute the avenue leading across the park. Pelargoniums presented a most dreary flowerless appearance, and only a few beds planted with carpet designs were at all bright and pleasing. One of the latter, a circle, contained a central specimen Cordyline, surrounded by Alternanthera paronychioides major, clusters of Sedum glaucum and Mentha, in the centre of which were plants of Chamsepeuce diacantha and clumps of the charming Nertera depressa covered with its pretty little orange-coloured berries. This bed was attractive and tasteful in design. The oblique parallel beds were planted with Centaurea ragusina in the centre, next a row of Viola Tory, a good dark purple, followed by Coleus Verschaffelti, Pelargonium Gold Leaf, Alternanthera magnifica, and Antennaria tomentosa. Lobelias appear to have succeeded pretty well here this season, for they were flowering most profusely at the time of our visit. The two best varieties there were Emperor William and pumila magnifica, both with good coloured flowers and similar in habit.—L. C.

STRAWBERRY FORCING.

I BEG to remind Mr. Bardney that the points under discussion between him and me do not relate to the practice of divesting the runners from the plants and nursing them in frames, as he now seeks to make it appear, but to layering in 3-inch pots versus layering in the fruiting pots. Does Mr. Bardney now repudiate what he stated in a leading article at pege 1? In that article he states that the system of layering in the fruiting pots is not only superior to the plan of severing the runners from the parent plants and nursing them in frames, but also to "layering in small pots;" and he goes on to explain that "the plants are, among other advantages, less liable to the attacks of red spider than when subject to the ordeal of drying two or three times a day, as is the case when layered in small pots," quite ignoring the fact that all good cultivators plunge the small pots in the soil previous to layering, and do not find it necessary to water more than once or twice a week. If Mr. Bardney has a plan of his own to recommend he need not exaggerate the difficulties of his neighbours' practice. If he withdraws the above statements regarding layering in small pots the dispute between us is at an end. As to Mr. Thomson's practice, I merely mentioned it to afford Mr. Bardney an instance he seemed to deaire, and now having got it he refrains from discussing the matter any further.—Forecer.

[Good Strawberries can be grown by both the modes alluded to. "FORCER" we know can grow them well according to the system he advocates, and Mr. Bardney can grow them equally well by layering the runners in fruiting pots. We have seen Mr. Bardney's plants, which are very fine.—EDS.]

DURING the past four years, not having accommodation to raise a sufficient stock of plants in the usual way for forcing, I adopted the following plan and found it answer admirably. When the plants have fruited they are hardened off for a short time, and then are turned out of the pots and plunged in a bed of thoroughly decomposed material, such as an old hotbed or one composed of leaf soil, &c., where in a short time the plants will produce vigorous runners, which when pegged down root freely and in a short time make very strong crowns. They are then raised and placed in the fruiting pots, the compost consisting of one-half good strong loam, one-fourth decayed cow manure with crushed bones, the remaining part soot and coarse sand; the plants are then placed in a frame for a short time and kept close. In two weeks the lights are removed, the plants being well established. I have found no plan so inexpensive and so successful as this, for the old stools can be utilised when the young plants are removed and can be planted out in the open ground, affording fruit late in the season.—A. CAMPBELL.

small raised panels of Alternanthera amoena, A. versicolor, and A. paronychioides major, edged with Echeverias. Pretty, but ing the best system of Strawberry layering, I beg to inform the designs, we think, were too small. The subtropical plants | you of a mode we adopted last season with good results. It is

simply layering the runners in pieces of turf about 2 or 3 inches square, which are plunged in ground with a stone or peg to keep the plant in its place. In a week the young plants will be ready either for potting or planting as the case may be. I read "FORCER'S" note last week on the ridge of soil plan, which I also like, and prefer to layering in pots. I only suggest this plan to your readers, as I have been in many places but never saw it practised, nor do I think has it been suggested by any of your recent correspondents. The chief advantages with me are an immense saving of labour, and the quickness with which the layers produce abundant roots. If any other grower has tried the method we should be pleased to be informed of the results.—W. IRVINE, Glossop Hall.

[We have practised the plan and can speak of it approvingly.--RDS.]

ABOUT LIVERPOOL .-- No. 3.

As equally good practice is often found in gardens of moderate extent as in larger and more famed establishments no apology is needed for describing in a brief and general manner the leading characteristics of the following gardens :-

OAKVALE HOUSE.

The grounds attached to the residence of J. E. Reynolds, Esq., Sandfield Park, West Derby, are not extensive, as is the case with many places in the neighbourhood of large towns, but the gardens are worthy of note for the number of good glass structures and the good work done in them. Three houses are devoted to Vines; the first being planted with Black Hamburghs and Muscat of Alexandria, and the Grapes indicated that great care and attention had been bestowed upon them. These Vines were bearing a heavy crop, the bunches were of average size and thoroughly well finished. The Muscats in this house were worked on the Black Hamburgh and were in fine condition, thus showing that Muscats and Hamburghs can be grown satisfactorily under the same conditions. In addition to these varieties the adjoining house contained a Vine of Gros Guillaume; the crop was heavy and the bunches large. The Vines are twenty-four years old. Three or four years ago they lacked vigour, which resulted in the Vines being lifted and supplied with a new border. They are now in excellent health. The third vinery contains Vines of Lady Downe's, Alicante, and Black Hamburghs about forty years old; the latter Vine, having five rods, has borne a hundred bunches each year for the past fourteen years. Camellias are planted out underneath, and are doing remarkably well.

Peaches have two houses devoted to their cultivation, each 60 feet long and 18 feet wide. The trees were carrying much too heavy crops, of which the gardener was well aware seven fruit to the square foot. A small house devoted to Orangefield Tomatoes and two others to Melons were profitably occupied. Orchids are grown in two houses, the one for cool species having at the end a very fine young plant of Lapageria alba, the other containing good plants of Phalænopeis, Vandas, Saccolabiums, Cattleya crispa, and three or four varieties of C. Mossie, Cypripediums, Miltonia spectabilis with thirty-four flower spikes, Leilia anceps and L. purpurata very good, also good examples of Dendrobiums, Oncidiums, and Calanthes. Pines are also well grown, the plants being stocky and bearing some good fruit. A large span-roofed house is devoted to a miscellaneous assortment of stove plants; another structure of the same size contains hardwooded plants—Azaleas, large and small, and a very large specimen of Rhododendron Gibsoni. In a house of flowering plants Calceolarias were fading; the plants were 3 feet through, and from 1 foot to 18 inches high. Some specimen Heaths in this house in flower were good, and many of the plants in the various houses had from time to fine and profitable house, the Peach trees on the back wall time won prominent positions in the shows at St. George's Hall, being a treat to see, and both owner and gardener have great. There is also a fernery, the plants being principally planted out on artificial rockwork faced with cement. The work has sized, highly finished, useful bunches being the object desired been well executed and presents a crystague and attained. Plants are limited but health and addinger been well executed and presents a grotesque appearance. Chrysanthemums are largely and well grown, and the place generally reflects great credit upon Mr. Wilson, the gardener.

managed, and well managed be it said, by one who has attained some notoriety in the gardening world. However greatly Mr. Roberts erred on a memorable occasion—and no one regrets it more than he does—he is unquestionably a good gardener and can well afford to rely on honest effort for maintaining his position as a cultivator. He is growing Chrysanthemums plants here. They are very numerous, and many of them are

again, and growing them well, but perhaps not for exhibition; indeed he appears to grow all kinds of plants well that he takes in hand. In the conservatory were some remarkably fine specimens of that fine old plant Campanula pyramidalis 8 feet in height, each plant having five or six imposing spikes. When thus grown few summer-flowering plants can surpass it for conservatory decoration. Peaches are extensively grown and Vines were in excellent condition, and were bearing capital crops of fruit. Vegetables were also good, and the entire garden afforded evidence of the ability and industry of the rardener.

ROBY HALL.

Mr. Pilkington's garden is of moderate size, and is very plemently situated—the view from the terrace embracing a fine stretch of country, including the Cheshire hills. There is a considerable extent of glass almost entirely devoted to fruit culture. The Peach trees and Vines were planted by Mr. Hims when he had charge of the garden, and were undoubtedly plasted well and have been well managed throughout. No Peach trees could be in finer condition—shoots thinly trained, leares dark green, and clean; wood medium, short-jointed, and bristling with plump buds. The Vines are equally satisfacory, and were bearing extraordinary crops of good fruit—Black Hamburgh, Trebbiano, Alicante, and Muscats. Plants are few but good, and the vegetable crops excellent. The flover garden, a sunken circular panel, was effectively planted, and the newer varieties of Roses were thriving well in the adjacent borders. A better stocked and better managed garden is 10t often seen than this, and Mr. Johnston is as courteous to vistors as he is skilled as a manager and cultivator.

COURT HEY.

This, the estate of Robertson Gladstone, Esq., nephew of the ex-Premier, adjoins the lands attached to Roby Hall. The gadens at Court Hey are notable for the extent and excellence of the fruit culture under glass, and certainly not less so for the astonishing amount of work accomplished by the gardener Mr. Ellsworthy and his two assistants. There are ranges of gass upwards of 200 feet in length, a walled kitchen garden of two acres, an orchard of half the size, the trees all pruned and well in hand, and extensive lawns. The most striking tature of the place was a grand house of Muscat Grapes. The Vines, which are thirty years old, were lifted three years ago. The borders are heavily top-dressed with rich manure, in which the roots feed. The laterals of the Vines are thinly trained and not too closely pinched; and the bunches, not numerous out regularly placed all over the roof, would average 4 ibs. in weight—a fine example of culture. Peaches and Nectarines, too, are equally well grown, thousands of fruit being of exhibition quality, and indeed have won many prizes at the Liverpool and other large provincial shows. Neither plants nor flowers are grown, nor is it possible that the gardens can be kept in high order, and that they can be rendered so productive as they are can only be the result of much thought and untiring industry. Mr. Ellsworthy certainly deserves a high meed of praise for the extent and excellence of his work.

STANDFIELD HOUSE,

The residence of J. S. Clayton, Esq., is situate at Waver-tree. A grand Peach range is the chief feature of this garden. The wall is lofty and 200 feet in length, every part of it from base to apex being covered with fruit in the season. The trees have recently been protected with glass, a substantial structure of which they are worthy. In the front is a double horizontal cordon of Pears and Plums, and at intervals in the border Tomatoes are grown trained to stakes. It is a very and attained. Plants are limited, but healthy; and adjoining the conservatory—a wing of it—is a well-appointed billiard room. Chrysanthemums, as in nearly all the gardens about Liverpool, are cultivated with care, and vegetable crops receive WHINMORE HOUSE.

a large share of the attention of Mr. Barton, whose work
The garden of W. D. Holt, Esq., could not be passed, as it is places him in the foremost rank of the gardeners of the district.

sufficiently good to have won many prizes at the Liverpool shows. Fine-foliage plants are also extensively grown, the houses being crowded with them, Caladiums especially being grown by hundreds. The conservatory was gay with plants in season, noteworthy amongst which were superior examples of Pancratium fragrans. Auriculas are also grown here, and probably two or three hundred or more Chrysanthemums. Shrubs and Conifers flourish well, and there are fine beds of Roses. Mr. Elliott, who has also the superintendence of the home farm, is a persevering, energetic, and able gardener.—J. W.

EASTER BEURRÉ PEAR.

In some notes on Pears sent to the Journal about this time last year I mentioned the difficulty I had experienced in properly ripening this Pear for several seasons. I had then a few dosen fine fruit on espaliers which were gathered in two batches on Ootober the 5th and 12th, and carefully stowed away in boxes in a wine cellar, where several other kinds of Pears have always kept very well, the fruit being brought forward in due season and placed in heat to ripen. Alout February some of the Easter Beurré were introduced into leat and failed, and since then from time to time the rest lave been tried with a like result, the fruit tarning scapy or roting outright. About three weeks ago the last half dozen were placed in a late vinery covered up in a box, and I now and you one of them to show how they have failed. Can any of your readers who succeed with this Pear tell us how they gow it and manage to mature it? From the specimen sent you vill see that so far as size and appearance goes I have nothing to complain of.—Essex.

[This is a remarkable instance of the Easter Beurré 10t pening. The fruit is large and handsome, well developed, ripening. and with all the appearance of perfection; but it is even now perfectly hard, and without any indication that it will e er melt until it is stewed. This is one of those unaccountaile cases of the capriciousness of this variety of Pear.]

THE HAILSTORM RELIEF FUND, 1879.

THE large number of applications that have been sent in to the Committee for relief from the fund, sixty-eight in number is indicative of the great amount of suffering caused by the hailstorm of August 3rd. Many of them are piteous appeals for assistance, if only small in amount, to meet pressing ne oessities, and it is an unfortunate fact that a large quantity of broken glass remains to be repaired for want of the means to replace it. The sixty-eight applications for relief represent as aggregate amount of stated damages amounting to £3600 In addition there is on the part of some members of the Committee knowledge of sufferers who are too modest to advance requests for assistance, but whose cases will not be overlooked The sum of £800 (the present amount of the fund, and from which the working expenses have to be deducted), is but a small sum comparatively with which to relieve so much of pressing necessity, and the Committee are making a further appeal for subscriptions. The sixty-eight applicants for relief reside in so large a district that it has been found necessary to sub-divide it into four divisions, and an investigation Sub-Committee has been appointed for each of them. Such Sub-Committees are now at work examining statements, overlooking breakages and repairs, and collecting reliable information so that each applicant may have his case fairly set forth. The work is heavy, but it is being readily and gladly done by properly qualified practical business men. It is important that the funds be shortly closed, so that concurrently with the consideration of the reports of the Investigation Sub-Committee, the Executive Committee can make their awards and administer relief. Will all who are willing to help be good snough to contribute the same without delay? The sooner the work can be brought to a close the more welcome will be the relief to be administered to those who are in sore need of it.-RICHARD DEAN, Ranclagh Road, Ealing; EDWARD KING, 14, King Street, Richmond, Co. Hon. Secs.

EUROPEAN FERNS. — V. a have received the first number of this work, now being published in monthly parts by Messrs. Cassell, Petter, & Galpin. It is from the pen of Mr. James
Britten, F.L.S., and is written in a most excellent, clear,
and concise style. The illustrations are correct and well Müller, government botanist of Victoria, has been rewarded

executed, both the coloured plates and the woodcuts, the former being produced by Mr. D. Blair, F.L.S.; and the type and paper are all that could be desired in a work of this description. By the publication of this work, as is stated in the prospectus, "it is believed that the culture of Ferns will be largely and permanently developed, and a new means opened up for the entertaining as well as useful employment of time. No expense has been spared in insuring a production which shall take first rank in regard to the accuracy and beauty of its coloured plates as well as the completeness of its informa-tion, whilst the price at which it will be published will place such a work for the first time within the reach of all lovers of Ferns. Specimens will be given of all the principal species of Ferns which flourish in Europe—the varieties found in the British Isles being treated with special fulness. The coloured plates will be painted from Nature, and will be reproduced so as to secure life-like representations of the objects figured. The text will contain a popular description of the different Ferns, with information as to the localities in which they are found, the soil and conditions suitable for their propagation. and such botanical information as will be generally acceptable. A very comprehensive introduction will also be given, which will prove of valuable assistance to all possessors of this work." But whether the continuation of the introduction from month to month will be the most convenient to the general reader is somewhat problematical.

NOTES AND GLEANINGS.

THE following statistics concerning the exhibits at the recent INTERNATIONAL POTATO SHOW may interest some of our readers. A total of 2101 dishes were staged, each containing nine tubers, which thus numbered 18,909. 1541 dishes contained English varieties, and 560 American varieties; the latter showing a decrease as compared with last year of 60 dishes, and the former an increase of 1062, the total last year being 1539; 120 English varieties were represented, and of these the most numerous were International Kidney 108 dishes. Magnum Bonum 96, Schoolmaster 58, Grampian 54, Porter's Excelsior 54; Red Emperor 39, and Woodstock Kidney 38. Twenty-eight American varieties were staged, the most abundant being Snowflake 69 dishes, Early Vermont 54, Beauty of Hebron 48, and Trophy 46.

THE undermentioned CHRYSANTHEMUM SOCIETIES will hold their Exhibitions on the following dates: - Walton. and Weybridge, November 18th; Kingston and Surbiton, November 20th and 21st; Putney and Fulham, November 11th and 12th; Camberwell and Peckham, November 24th and 25th 🕏 Twickenham, November 12th and 13th; Richmond, November 18th and 19th; Hackney, November 19th and 20th.

In the year 1880, the jubilee year of the independence of the kingdom, a NATORAL EXHIBITION is to be held in Belgium. It will be entirely devoted to national products. The section appropriated to horticulture provides divisions for flowers, fruits, and vegetables respectively, and preparations are being made for a very extensive and imposing display.

THE last field meeting of the year of the WOOLHOPE NATURALISTS' FIELD CLUB is held to-day (Thursday, October 2nd) at Hereford, for a "foray among the funguses" in the Foxley Woods, a soirce being afterwards held and papers read at the residence of Thomas Cam, Esq. In previous years the Pomona Committee of the Club held their meeting and annual exhibition of fruits at the same time as the fungus gathering; but this year the fruit exhibition will be held separately in the Free Library at Hereford on the 29th and 30th inst., the lateness of the season having rendered the change advisable. It will be in other respects convenient, as the dual programme was too great for one day; and, further, it is not easy to fix a date when both fungi and fruit can be in the best condition. Prizes for fruit—Apples and Pears—are offered in forty-one classes, divided into sections for nurserymen or market gardeners, amateurs (including gentlemen's gardeners), a section open to all and from anywhere," one for vintage fruit, and one for cottagers. Three prises are provided in each class, not of great amounts, but sufficient to insure as large and interesting an exhibition as the season permits.

NEXT year the CONGRESS OF GERMAN HORTECUL-TURISTS will meet at Bremen. This year it was held at Cassel.

for his colonial services as a naturalist with the Knight Commandership of the Order of St. Michael and St. George.

- The Committee and Officers of the Pelargonium Socrety for 1880, as settled at the annual meeting referred to Manor; Vice-President, W. B. Kellock, Esq., Stamford Hill; Hon. Treasurer, Dr. Denny; Hon. Secretary, Mr. Thomas Moore; Committee, Mesers. W. Bull, H. Cannell, J. Catlin, J. George, J. Douglas, T. Dixon, H. Little, S. Hibberd, Dr. Hogg, J. James, J. R. Kinghorn, J. T. D. Llewellyn, Dr. Masters, Rev. C. P. Peach, C. E. Pearson, Dr. Sankey, F. T. Smith, G. Smith, Edmonton; G. Smith, Hornsey Road; C. Turner, Rev. A. Matthews, J. McIntosh, H. J. Veitch, G. F. Wilson, and H. Webb.
- A MEETING of the CANTERBURY AND EAST KENT ROSE SOCIETY was held at the Rose Hotel, Canterbury, on the 24th inst., Captain Lambert in the chair, when a very satisfactory report was handed in by the Secretaries announcing a substantial balance in hand. It was determined that the Exhibition for next year should be held on Thursday, July 1st, and that there should be additions made both in the value and number of the prizes.
- THE gardeners of Preston Hall, Aylesford, intend presenting Mr. WILLIAM BRADLEY, head gardener, on the occasion of his leaving, a handsome black marble clock, beautifully gilded and inlaid with malachite. The clock bears the following inscription:—"Presented to Mr. William Bradley by the gardeners, on the occasion of his leaving Preston Hall, October, 1879."
- On the night of the 29th ult the thermometer in the gardens at Axwell Park, near Newcastle-on-Tyne, fell to 25°, and such tender plants as Dahlias, Perilla, Heliotropes, &c., were despoiled of their beauty, being considerably injured by
- WE have received from Messrs. Edward Webb & Sons, Wordsley, Stourbridge, a box of ASTERS grown in their trial grounds at Kinver Hill. The blooms are very good and the colours varied, including creamy white, bright pink, purplish blue (very rich), white with pink and purple outer florets, and a striking striped variety, the florets being purple clearly margined with white. All the blooms are well imbricated and of good size, and represent an excellent strain of these valuable autumn flowers. We have also received specimens of Webb's SUMMERHILL CABBAGE LETTUCE. The heads are very large, close, green, faintly tinged with purple, and are crisp, sweet, and excellent.
- Mr. Luckhurst describes the Langley Park Greet GOOSEBERRY as "a delicious variety for the dessert. The tree is of erect and bushy growth and an abundant cropper. When hurriedly replying to a correspondent recently, just on the eve of going to press, we had for the moment forgotten this variety, which we really know very well, and it is described as follows in the "Gardeners' Year Book" of 1871:—"Frut medium, ovate, hairy, light green; thin skin. Very rich in flavour.
- —— An experienced cultivator writes to us as follows on EXPENING GLADIOLUS CORMS:—"Gladioluses are, as in 1874, exceptionally late, and it will be necessary to take steps immediately to ripen the corms for next year. Where the collection is only an ordinary one the best way of doing so is to lift and not the plants as they stand and finish them off under glass. This was done in 1877 with good results. Where there are to many plants for potting, they could be lifted with good balk and packed closely on borders of houses until the foliage has decayed. But this is not such a good plan as potting, as they experience no check so managed, the spikes which are opening conservatories.
- 24th and 25th ult. Purchasers from the south of England prize is offered for a dish of fruit without specifying quantity. were represented by Sir Trevor Lawrence, Bart., M.P., Burford For instance, one exhibitor shows a quart of Strawberries, Lodge, Dorking; Mr. Day, Tottenham; and Mr. B. S. Williams, perhaps another three times as many. Some judges possess an

and Sons, Clovenfords, offered a portion of their stock at the same time, a plant of the Dalkeith variety of Vanda tricolor fetching £30 10a.; Odontoglessum vexillarium, £22. Good prices were also obtained for other plants sold.

IT may interest our readers to know that the OLD VIJE AT HAMPTON COURT PALACE is this year bearing an excellent crop of Grapes. There are about 1500 bunches, the whole of which are finishing off extremely well; the burches are larger, and the berries considerably finer than has been the case for many years. Many bunches have already been gathered and sent to the Royal table at an earler date than usual, as this old Vine is noted for the fresness of the Grapes late in the season. The excellence of the Grapes may probably be due to the unusually wet summer, as the Vine has been known to flag in very dry sesions.

- IT is a little surprising that that fine lawn ornament ARTNDO CONSPICUA is not more frequently seen in gardens and pleasure grounds. Its compact yet very graceful habit and silvery plumes of inflorescence render it highly ornamental, and it possesses the advantage of flowering much earlier than the Pampas Grass. It is also equally hardy, or perhaps more harly than the Pampas Grass, for we have seen examples of both plants in the same garden, and the Gynerium has been much injured by the severity of last winter, while the Arundo appears as healthy and fresh as ever. It was discovered by Baks and Solander during Cook's first voyage, and gathered duing his second voyage by Forster, and was introduced to Key about 1843. It abounds in New Zealand, where it grows innoist positions. It thrives in the ordinary soil of English gadens.

 Mr. Alfred Taylor, late foreman at Marston House, Fame, has been appointed gardener to Lord de Mauley, Lagford House, Lechlade.

DUPLICATE ROSES.

As Secretary of the National Rese Society I shall be quite rady to undertake the work which "Oxonian" suggests, but Foresee great difficulties.

It has been frequently stated that there is no difference the been frequently stated that there is no difference between Ferdinand de Lesseps, Maurice Bernardin, and Exposition de Brie; yet, when talking over the matter with Ir. William Paul at Brie, he said that he would undertake, if qually good blooms of the three varieties were mixed together, to distinguish each variety. Again, Mdlle. Eugénie erdier and Madame Marie Finger are looked upon by many is identical, yet Mr. Cant in his last catalogue says they are quite distinct.

I would suggest these questions :--1, What Roses do you conider identical? 2, Ought they to be shown in the same stand? and 3, If shown ought they to score anything against the exnibitor?—D., Deal.

NOTES ON JUDGING.

Does it not seem a pity that we have not in judging somehing more definite than at present exists as regards adjudisating the prizes? Attending shows frequently and coming in contact with judges of eminence in their respective departments, I am surprised to find what divergence of opinion exists amongst them as to the claims of competing collections; ndeed, the judging seems only a matter of opinion. If some standard rules were issued by some competent authority I cannot help thinking much benefit would result.

Further, herticultural societies ought to make their schedules more explicit and express definitely what they mean. Say, for instance, if a prize is offered for eight dishes of fruit fit or have to open making the plants serviceable for placing in for table and one of these dishes simply is not fit, however conservatories."

—— THE collection of Orchids belonging to the lite them first? If so, the logical sequence is—they have given the Mr. Mila, Arbroath, was sold by auction at Edinburgh on the prize for seven dishes, not eight. Then, again, sometimes a Holloway. The following were amongst the highest prices inherent weakness for quantity, consequently give the prize to realised:—Lycaste Skinneri alba, 41 guineas; Phalsenopsis the greater, while perhaps the smaller possesses the greater per-Schillerians, 37 guineas; Lælia elegans Turnerii, £30; Odon-centage of good fruit. Then, again the respective values of toglessum newium majus, £22; Maadevallia coccinea, 16 guineas; fruit. How many points does a good Pine possess above M. Harryana superba, 14 guineas; Lælia Perrinii, 11 guineas. Grapes? And so on with other fruit. Also, what is the relative whole amount realised was over £1000. Messrs, Thomson tive value of Muscat of Alexandria, Black Hamburgh, and other Grapes, which follow next in order of merit? The same may be said of plants. Perhaps there is in them more divergence of opinion still. I know no hard and fast line ean be laid down, and a judge must be guided by his own discretion, yet he would judge the more easily and satisfactorily to himself and others were he guided by established principles; hence the subject is worthy of discussion.—B. COWAN.

BIRMINGHAM CHRYSANTHEMUM SOCIETY.

In the early part of the year it was proposed by several of your correspondents to hold a National Show of cut blooms of Chrysanthemums, having reference more particularly to a friendly contest between the northern and southern growers. It was also proposed that the Show should be held in Birningham, as being centrally situated, and a good show always leing held there the Committee of the Birmingham Chrysanthemum Society made a liberal offer of money towards that oject, and other societies have also nobly contributed; but as there is still a deficiency on the amount proposed to be raised of £18, and no money having been sent from any of the Loadon district societies or growers, and as our Show takes plac on the 26th and 27th of November, our Committee have decided to return the amounts received unless the above sum is received by the 16th of October. I feel sure that all lovers of hortculture will regret that such an excellent opportunity of mating a splendid display of cut flowers should be allowed to pas by for the want of a little additional support.—C. Rederin, Secretary.

LAKE VIEW, CHELTENHAM. THE RESIDENCE OF G. NEVILLE WYATT, ESQ.

THROUGH the kindness of my friend Dr. Abercrombi, so well known in the horticultural world as a grower and riser of Carnations and Picotees, I had the opportunity the cher day of paying a visit to the most complete example of rw in wrbe that I have ever seen—that is, if Cheltenham be allowd to be an wrbs. It is itself so pleasantly situated with its gardns, and promenades, and squares that one can hardly realise wat a busy town it is and how many find shelter within it dumg the season. It is essentially a winter place, resorted to alsoby many an Indian officer, who finds in its balmy air a pleasaner resting place than is to be had in many places in our island; while of late years the wonderful success of its colleges both for boys and girls has added largely to its population. Wel, it is just opposite to the grounds of the Boys' College that yw enter those of Lake House, the residence of G. Neville Wyst, Esq., where, besides a large horticultural establishment, my be seen all the surroundings of a country gentleman's hous, as much so as if situated miles from a telegraph or a doctor, and a few of the features of which I wish to notice.

The conservatory attached to the house presented a gay aid pleasing appearance, although the principal flowers that helpd to fill it were very simple; amongst them an old but somewhat neglected plant, Francoa ramosa, held a chief place. Is long spikes of snowy blossoms so gracefully pendant were vey pleasing; and they, moreover, have this advantage, that thy are most useful for bouquets, and also are very suggestive if being well adapted for a wreath for ladies' hair. It is an od hardy plant, but except in the west of England I never see it. The common Campanula pyramidalis and the more effective Campanula medium calycanthema with its various shade of blue and white also formed admirable plants for the corservatory where people can be induced to employ such common things. Passing from the conservatory into the garden found a range of houses of all kinds—stoves, vineries, an Orchic range, a Peach and Nectarine range, &c. Pines had been grown and a few still lingered on, but they were doomed. The introduction of those from St. Michaels made, said Mr. Wyatt, the growing of them at home unnecessary, and obviated the expense and trouble. This is quite true, and English Pine-grow ing, like a good many other things, will have to give way to the foreigner. In the Azalea house was a good collection or pyramidal trees, excellently grown and well trained, and promising well for next spring's display. Amongst the stow plants I noticed that Hibiscuses were well grown and ver-bright and fine; Dipladenia amabilis, and the various othe plants one generally sees in stoves. Then there was a long range of Orchid houses—a lean-to, which was filled with a fin collection, comprising all the best kinds, and all apparently in excellent health. The shading here was of bamboo, that intro

duced by the Colchester Bulb and Seed Company; but instead of the shading lying on the glass there was a framework of wood raised about a foot above it, and on this the bambos shading rested, thus affording a circulation of air while effectually shading the house. We then passed into a large range of Peaches and Nectarines, all in the most vigorous health; some had ripened-off their crop, others were in full bearing, and I can testify to their excellent quality, some of the newer varieties raised by Mr. Rivers being grown and highly approved of.

The bedding-out in the garden has been very considerably diminished, and the most noticeable thing I saw was the oldfashioned Mesembryanthemum tricolor, which with the brilliant sun shining on it (a rare visitant this year) was very showy. We then passed through a meadow out into a monster garden, a piece of eight acres, entirely surrounded by wall, and the wall covered with fruit trees; and here let me say that on the whole of this wall—on which were large numbers of Peach and Nectarine trees, and of considerable size—I did not see but one tree on which there was a sign of blister; the leaves had not been taken off, but the trees were thick with them in finehealth, with that glaucous tinge that so indicates contentment with their lot. But what shall I say of the Gooseberries? Here and all about Cheltenham they presented a most miserable aspect, not a leaf left on whole quarters, and the fruit consequently poor and shrivelled. Men were employed beating the bushes, and then destroying with the flat of the spade all that fell. By-the-by, is it not a mistake to refer such havoc as this to the caterpillar of the Gooseberry moth? Is it not the sawfly that does the damage? There was a large breadth of Peas, and I found that the favourite, in exclusion of all others, is Veitch's Perfection; while in Potatoes Suttons' Magnum Bonum bore off the palm. Nothing could exceed the vigour of the plants, which were planted in rows 4 feet apart, and 3 feet in the rows. Disease having made its appearance Mr. Wyatt had the plants dusted with lime, and so far it had appeared effectually to check it, as no symptoms of progress appeared enectually to check it, as no symptoms of progress-were visible. The haulm, as it may be supposed, was very vigorous and strong, and I have no doubt under such liberal treatment the produce will be heavy, as heavy as possible this wretched season. From this garden we passed into the shrub-bery, which skirts the lake, and then by a long herbaceous border we reach the lawn in front of the house. In this herbaceous border were to be found many old-fashioned plants, with Roses and shrubs mixed amongst them.

I have thus cursorily glanced at some of the contents of this delightful residence. Mr. Wyatt is well known as a most liberal supporter of horticulture, and it is always satisfactory to find that where this is the case results which must be gratifying to him are obtained by the care of an intelligent gardener under his own personal superintendence, while to myself it was a great treat, increased by the courtesy and kindness of the master.—D., Deal.

WELLINGTONIA GIGANTEA.

SOME very fine specimens of this handsome Conifer can be seen at Muckross, several of which are bearing cones freely and appear extremely flourishing. I will give the dimensions of two that are remarkable for their symmetry and vigour. One is 51 feet high with a girth at the base of 9 feet 6 inches, while the branches cover a space of 90 feet in circumference. Another is 53 feet high, girth at the base 8 feet. There are also others of nearly equal dimensions, all likely to become nagnificent specimens. A few trees planted at the same time is those referred to, and apparently in as favourable a situation, lave not succeeded nearly so well. This led me to inquire how the ground was prepared for the reception of the plants, and I have ascertained in confirmation of my own experience that those which have succeeded were planted in a deep aluvial soil thoroughly drained, proving that draining is of vial importance.—Andrew Campbell.

APPLE DR. HOGG.

THIS is a novelty of considerable promise, being a constant and heavy cropper, and bearing large handsome fruit of the inest quality, which is in season from September to March.

It was first exhibited before the Fruit Committee of the Royal Horticultural Society on November 19th, 1878, by Mr. Sidney Ford, The Gardens, Leonardslee, Horsham, and was then described as resembling Calville Blanche in shape and colour, and with the delicate flesh of that variety. It was December 17th. It was brought forward again, and supertest ordered to be cooked and reported at the next meeting on on as follows by Sir Charles Strickland, Bart., who had been

requested to examine some varieties of cooking Apples exhi- | Calville, probably a coodling from it. Melts perfectly, does bited at the last meeting :- Dr. Hogg is very like the White | not fall at all, july, alightly soid, very rich and sugary, deli-

cate aroma. A first-rate taking Apple." A first-class certi- closely around the stems early in the season, failed this year ficate was then awarded.

Dr. Hogg may be described as an excellent dessert and kitchen Apple, good also for jelly. The flesh is white, tender, juicy, sweet and briskly flavoured; skin when ripe rich golden yellow faintly streaked with red on the side next the sun, large and showy; eye generally large; stalk slender, set in a deep cavity. Very hardy, healthy, and productive, making good standard and pyramidal trees.

Our illustration is furnished by Messas. Wm. Faul & Son of

Waltham Cross, by whom this Apple is being distributed.

HORTICULTURAL NOTES.—No. 2. NEWBURN AND DISTRICT-WELFORD PARK.

THIS, the scat of C. Eyre, Esq., is a few miles from Newbury, the nearest station to it being Kintbury, which is about four miles distant. The gardens are badly situated, being much too near a running stream; as a consequence, some parts of it are imperfectly diained, and spring frosts are very prevalent. In spite of these drambacks, however, under the skilful management of Mr. C. Ross it produces an abundance of excellent vegetables and firmit, some of which are sometimes successfully exhibited both at the London and local shows. The rainfall was remarkably heavy here on the night of August 2nd, as according to Mr. Ross's rain-gauge no less than 21 inches fell in a few hours, washing down the walks, completely filling the one large stokehole, &c. The range of houses situated at the lowest part of the kitchen garden is extensive, but some of them are much too flat, and are being gradually raised to a more satisfactory pitch. Fruit of every description is well grown, and nothing could be finer than the Peach and Nectarine trees. They are grown on the back walls, and also on low circular trellies in front of these. A Prince of Wales Peach tree nine years old, occupying a space 24 by 12 feet, was carrying seventeen dozen very fine fruit, and there were others very large. Violette Estive Peach and Pitmaston Orange and Elruge Nectarines are the favourites for all purposes here. Noblesse Peach is grown, but does not set well. Grapes generally were carrying good crops, notably the Muscat of Alexandria. These during flowering time are kept as nearly as possible at about 70°, but they are often unavoidably below that temperature. Golden Hamburgh on its own roots failed, but does well graffied on the Black Hamburgh, and is a favourite at the table, but does not keep well. Figs planted in a low-fronted house are grown in the bush fashion and succeed admirably. In the same house a large quantity of Tomatoes were growing, there being a great and continuous demand for that useful fruit. They are fruited in 12-inch pots, are kept pingshed to single stems, which are trained thinly pots, are kept pinched to single stems, which are trained up the roof, and the crop was very heavy and good. To follow these others were planted at the base of south walls, the fruit of which at the time of our visit was commencing to ripen, system followed, and this is worthy of imitation, is as follows:—the seed is sown early, and the plants grown on in either 5-inch or 6-inch pots, kept pinched to a single stem, and about three tiers of fruit set before being finally hardened off, and planted out as early in June as the weather permits. Several varieties are grown, but the favourite is the Trophy. Pines, especially the Smooth Cayenne, of which Mr. Ross is a moted grower, were looking well, the fruit promising to be as fine as usual. The soil employed for these consists only of very fibrous loam and bone dust, not that bone dust usually made Mr. Boss heing independent of external supplies having used, Mr. Ross being independent of external supplies, having fortunately discovered a cemetery, or burying place of horse bones, in connection with a kennel of fox hounds. The bones are said to be one hundred years old, and they crumble up readily, and so useful and effective are they that we, toe, wish we could discover a similar valuable supply. Mr. Ross is also a good plant-grower, and has under his charge many valuable specimens. The kitchen garden is well walled in, and the crops were looking well, but the Potatoes were badly diseased.

The past winter completely killed three fine Peach trees on the walls, and those alive look very "queer." Pears on the walls are very healthy and fruitful, the best being Glou Morceau, Monarch, Passe Colmar, Joséphine de Malines, and Jargonelle. The crops of Apples, Cherries, and Plums were very light. Small fruits were abundant, but the caterpillar was very destructive, especially among the Gooseberry bushes. A local preventive, Gorse or Fuzze twigs packed

for the first time, owing, Mr. Ross thinks, to its being rather imperfectly done, the result of previous immunities. This practice has been for many years followed in this neighbourhood, and is worth a trial where spent tan is not to be had. The Grove End Scarlet Strawberry is the favourite for forcing; and for the table Keens' Seedling, Sir Joseph Paxton, Sir C. Napier, Dr. Hogg, and Elton Pine are grown. The pleasure grounds are not extensive, but are very pretty and well kept, the bedding-out being well done. Rhododendrons in great variety are remarkably healthy, and a fine specimen of Pices. Pinsapo 36 feet high and very symmetrical is noteworthy. A good-sized conservatory adjoining the residence is well stocked with fine healthy Camellias, &c., and flowering grandly; up the pillars and on the roof was a large plant of the beautiful Bignonia cherere. Mr. Ross remarked that this species will not flower freely till it has been established four or five years.

HAMPSTBAD PARK.

On our return drive from Welford Park we called at this, one of the residences of the Marquis of Donegal; not so much to note what it is, but rather what it has been, and certainly did not begrudge the time so spent. The kitchen garden, which at one time must have been one of the grandest in the kingdom, is seven acres in extent and well walled in. high and massive stone pillars of the old gateways are remarkable; the carved groups of fruits and flowers, in excellent preservation, being fine and much admired by connoisseurs. The place, however, is not kept up by the present lessee, no young fruit trees having been planted for many years; as a consequence the walls are indifferently furnished. The number of men employed too, is altogether inadequate; and taking this into consideration Mr. Milien, the painstaking gardener in charge, is to be commended for the way in which the kitchen garden and the extensive and picturesque grounds are kept. The amount of glass is comparatively small and not of the best description. The very elaborate apparatus for heating a vinery by steam has long been unworkable, but is a great curiosity nevertheless. It is altogether a very complicated and expensive affair, which contracts very unfavourably with the heating apparatus of the present day. Mr. Millen, who grows Fotatoes very extensively and well, recommends Mona's Pride, Myatt's Ashleaf, Improved Early Hammersmith, and Fox's Seedling for the early supply; and for the main crop, Covent Garden Perfection, Schoolmaster, Rector of Woodstock, Woodstock Kidney, Suttons' Magnum Bonum, Late Rose, and Irish Regent. Here again Pears only were plentiful; Passe Colmar, Louise Bonne of Jensey, Easter Beurré, Hacon's Incomparable, Ne Plus Meuris, Duchesse d'Angoulême, Beurré de Capiaumont, Winter Nelis, and Marie Louise being very fruitful. A very moderate outlay might easily transform Hampstead Park into one of the best places in the kingdom.

LOCKINGS PARK.

This is the residence of a very popular and well-known gentileman.—wiz., Col. Loyd Lindsay. It is best reached by taking train from Banding to Wantage, and is about four miles from the latter place. It is a fine place, and is very successfully managed by the gardener in charge, Mr. J. Atkins, who is well known among other things as being a very good Grapegrower. This season the Grapes are again very fine, the house of Muscat of Alexandria remarkably so. The crop of this useful variety is very heavy, the bunches large and uniform, the berries also large and for the season well coloured. The temperature at their blooming time was kept as near 70° as possible, and with occasional tappings they set as freely as Hamburghs. The roots of these and all the Vines have free access to both in and outside borders, and the good management of these is the true secret of Mr. Atkins' success. Pearson's Golden Queen as grown here is one of the best of Grapes. It is grafted on Foster's Seedling, and is doing remarkably well, being fine in bunch and berry, and is in every respect a good companion for the Black Alicante, which also is well grown and keeps famously. Foster's Seedling and Buckland Sweetwater are both forced here, the former being the best. The crop of Peaches and Nectarines under glass were both heavy and good, the trees being very healthy. Royal George and Grosse Mignonne Peaches and Elruge Nectarine are found the best for forcing. Impératrice Albert Victor was very good, but is inferior to the Elruge. Figs are well grown, especially the Brown Turkey. There is a great variety of plants grown, among them being several very good specimens. Of

Ferns Alsophila excelsa, Lomaria gibba, Gymnogramma Massonii, Adiantum tenerum, A. gracillimum, Davallia Mooreana, &c., were very fine; and very noticeable among the other foliage plants were the specimens of Cocos Weddelliana, Kentia Canterburyana, Maranta sebrina, Alocasia macrorhiza variegata, &c. The crop of Peaches generally on the walls was rather below the average, but Early Grosse Mignonne, Early Affred, Royal Charlotte, Royal George, and Violette Hâtive were notable exceptions. The crop of Pears on standard trees was a failure, but on the walls Winter Nélis, Beurré Diel, Beurré Clairgeau, Jargonelle, Glou Morceau, Louise Bonne of Jersey, and Williams' Bon Chrêtien were carrying good average crops of fair-sized fruit. Plums grown as standards failed to bear on the walls: the best were Green Gage, Rivers' Early Favourite, Golden Gage, and Denyer's Victoria. Apricots were a failure. Strawberries were very abundant, the best being Keens' Seedling, President, and Loxford Hall. Fruit of the latter were very fine indeed and of good flavour. James Veitch produced an abundance of large fruit, but the quality was very indifferent. The soil of the kitchen garden is a "made soil" resting on a chalky subsoil, and the crops generally were looking well. The same remark applies to the pleasure grounds, the flower beds, including six large carpet beds, looking well in spite of the unfavourable season.—W. Leguuden.

CURRENT TOPICS.

In reference to stealing fruit at Newcastle-on-Tyne, I wish to say that some of my fruit was stolen. I had left, and the man was found with fruit on him; if I had been there I certainly would have prosecuted, and after what has passed shall do so. It is no excuse to say there is a foolish supposition about taking fruit; the man was not a visitor but a gardener and must have known better, and Mr. Gillespie has made a great mistake to allow it to pass. The value of fruit shown at Newcastle was so great that a great amount of injury might have been done, and pilfering must be put a stop to.

Dephicate Roses.—In answer to "GMONIAN," I desire to say

Deplicate Roses.—In answer to "OMONIAN," I desire to say that all the Roses mentioned as duplicates have been grown by me; but with one exception—Ferdinand de Lesseps and Camille Bernardin—I cannot agree to their identity. I have looked carefully, too, at so-called duplicates at shows when judging, and can always see the difference. Exposition de Brie is supposed to be a duplicate. It is perfectly distinct in habit from any other Rose; so, too, see Reynolds Hole and Sultan of Zansibar, also Fisher Holmes and Dake of Wellington. It might as well be said that certain so-called distinct Zonal Pelargoniums which certainly run near together are the same, and yet I have 120 to 180 varieties which I could pick out without a label to them.

A. Boyle is right about giving Geranium plants room. I have done it for a long time. I always put a plant of every sort in the kitchen garden a yard apart, also plant them in a bank between Rose trees as I do Phloxes and Gladioli; but I still plant self beds, and am sure with proper treatment, properly prepared plants, not tunned out of cold frames or thumb pots, or cutting boxes, or wintered haphassed, that with the present great improvement in Zonals chiefly brought about by Mr. Pearson of Chilwell and Dr. Denny, we need have no fear of what Mr. Boyle oalls firms rilants.

Tear of what Mr. Boyle calls filmsy plants.

I think "F. W. J." gives a useful list of Roses for towns.

"BICEPS" falling foul of Général Jacqueminot was to me a
mystery. I do not accept his summer dressing with its accompanying smells, and if he must use it cover with dry sahes and
soil. Over-watering, over-liquid-manuring, and other fads are
often the bane of many Roses. I never see green fly or an unhealthy shoot, or a mildewed one in my garden. Winter
mulching, proper pruning, and avoidance of Dog Roses as
stocks, especially the seedling Briar, which is late, uncertain,
and unsatisfactory to me except in heavy soils, is still my
opinion. There is nothing like the Manetti stock for ordinary
garden Roses, which form the staple of nine gardens out of
ten. I think "WYLD SAVAGE" is right about similarities in
varieties, and they can be easily grouped and classified, and
I much doubt if our Rose lists with regard to Teas and
Bourbons do not want it.—C. P. PRECH.

NOTES ON VILLA AND SUBURBAN GARDENING.

KITCHEN GARDEN.—Cauliflowers and Lettuces raised from seed sown at the end of August should now be planted out where they are to remain during the winter. Prepare a piece of ground in a

sheltered and warm position, and on it place sufficient handlights or spare garden frames, and place the young plants about 4 inches apart; give only sufficient water to settle the soil around the plants, and allow them to be fully exposed to light and air until the nights become colder. The hardier and sturdier the plants are at the commencement of winter the better can they withstand intense cold. It is also a good plan, and especially for Lettuces, to plant the narrow borders at the foot of south walls thickly with the varieties Bath or Brown Cos and Hardy Hammersmith Cabbage, and thin them out in the spring; in this manner very good Lettuces can be obtained, and in ordinary winters a number of Cauliflowers similarly planted will survive with no other protection, and produce heads the following summer almost equal to those sheltered in frames, &c. Hoe and stir the ground amongst the crops of winter Spinach, and thin out the plants so that they may become well matured and strong. As Endive plants, both the curled and broad-leaved varieties, attain their full size they must be blanched. There are various ways of blanching them successfully, but the most simple is covering each plant with a slate or tile. Those who have the convenience of a small warm dark shed or a Mushroom house can readily have a constant supply of well-blanched Endive by occasionally lifting sufficient plants without disturbing the roots and placing them in the shed moderately close together. Crops of Onions not yet harvested must be gathered without further delay, and the main crop of Cabbages should be planted out as soon as possible. As Celery advances in height let it be earthed up, choosing a dry day for the purpose. Do not earth above the hearts, and be careful not to allow the soil to enter the hearts of the plants. It is by far the safest plan before commencing to earth up to tie each plant around with a piece of matting; this will exclude the soil, and also prevent worms from eating the inside of the blanched foliage. As Vegetable

FLOWER GARDEN AND SHRUBBERIES.—Any alterations that are to be made either in replanting or making improvements should be noted and commenced at once. Both evergreen and deciduous trees will soon be ready for removing, and if this is carefully done they will stand a better chance of becoming established than if planted later in the winter. Turf laid now will also unite quickly, and the ground will become consolidated before the spring. As long as frosts keep off everything should be done to maintain the flower garden in as good order as the season will permit, but as soon as all hope of further beauty is past decide on the arrangement for spring bedding, for it is necessary that all bulbs such as Hyacinths and Tulips should be planted as early as possible; also have sufficient quantities in readiness of Wallflowers, Myosotises, Silenes, Pansies, Polyanthus, Daisies, &c., for the earlier these are planted the better chance they have of becoming established and blooming correspondingly early next

Spring.

Chrysanthenums.—These are generally late in setting their flower buds this season, but the majority of the plants are looking very promising; the foliage is clean and bright, and though possibly rather late in blooming, a good average display may be expected. As the buds become sufficiently large to handle those not required must be removed, and the plants will be benefited with liquid manure from this time. Supplies of weak guano water will render the foliage of a bright deep colour, but we have an opinion that flowers of plants supplied too freely with guano are liable to damp off. A pinch of Standen's manure will also wonderfully improve the foliage. Supply stimulants weak and often, and if the surface of the soil becomes caked stir it and keep it free from weeds and young suckers. While the weather keeps open allow the plants to remain out of doors, but the effect of 7° or 8° of frost to many of the early varieties would be quite ruinous; therefore, if there is any fear of this they should be placed under cover. Keep them well supplied with water, and secure each growth to a stake, for the wood is very brittle. Any attention these plants receive now will be amply returned in the display they will make for the next two months.

Rosss.—Note all the dead and dying plants, and make arrangements for supplying their places. The earlier the orders are given to the nurserymen the sooner in the season will the plants be supplied, and early orders oftentimes bring the strongest plants. Cuttings will now strike readily if the hard ripened wood of this summer's growth are taken off, cut into lengths of about 6 inches, and inserted deeply in lines about a foot apart, and about 8 inches apart in the lines. The best position is at the foot of a southwest wall, and in a piece of ground that is somewhat light and open. But any warm border will answer the same purpose. Each variety should be kept separate and labelled. If new plantations are required for next season the ground should be well trenched in readiness, incorporating among it some well-decayed manure. The Briar stock delights in a cool loamy soil, while the Manetti prefers a lighter and more porous soil. It will be well to bear this in mind when giving orders. In most villa gardens Roses on the Manetti may be cultivated successfully by taking care to cover the budded part when planting; but as all Roses do not

thrive as freely on the one stock as the other, it would be well to cultivate Roses on the various stocks. It is the best to plant Roses in beds, then they can be all treated liberally and alike; but where it is necessary to plant standards singly have the ground well broken-up and suitable soil placed for them.

WORK FOR THE WEEK.

KITCHEN GARDEN:

CAULIFLOWER plants will now be ready for moving from the seed beds. Select the strongest for transferring to handlights. Rather strong loam is most suitable and conducive to sturdy growth. The plants must be unprotected as long as it is safe to growth. The plants must be unprotected as long as it is sare to render them hardy; the lights should only be employed in case of frost or heavy cold rains, and even then air should be admitted. Lettuces for the spring and early summer supply should be planted at once, so that they be well established before winter. A sheltered border should be chosen, planting them in rows a foot apart. Lettuces for the spring and early summer supply may warm wall be grown along with Pass, the rows of the latter which very well be grown along with Peas; the rows of the latter which will presently be sown may be 4 feet apart, admitting of three rows of Lettuces between, a row of Stanstead Park Cabbage Lettuce no either side of the Peas, and a row of black-seeded Bath Cos between these. If the soil be light it is necessary that it be made moderately firm by treading and then raking to form a fine surface. There must not be any neglect in dusting with wood ashes, soot, or lime to keep vermin in check, whilst all vacancies should be filled up promptly so as to secure a good plantation. When the main crop is planted a number of the remaining plants of the Cos varieties should be pricked out into a prepared bed in a sheltered position; the plants, if they winter safely, will be very useful in spring for transplanting. Endive plants from the late sowings may be planted at the foot of walls, or they will succeed sowings may be planted at the foot of walls, or they will succeed under similar conditions to the Lettuces. Lettuces which are to give a continuous supply when that outside is exhausted should be lifted and planted in pits or frames. Endive plants, too, for use during the winter months should also be placed in pits or frames. Much labour is entailed in the preservation of these plants in cold frames. Where the demand is large shallow pits with moveable lights with the command of artificial heat to exclude frost are accessor. clude frost are necessary to secure supplies in good condition throughout the winter months. The ground rendered vacant by the removal of Potatoes and Onions being prepared by well manurand only occupied by Onions being prepared by wen manuring and digging will be available for planting Cabbages. Ground previously occupied by Onions is very suitable for Cabbages. Earlier planted crops should be frequently hoed, and when necessary have a moderate earthing. Lose no favourable opportunity of attending to the earthing of Celery, tying up Lettuces and Endive. Parsley in pits should be well thinned, but still fully exposed except in case of drenching rains. If there be no plants as yet in pits strong plants from the spring acquiring may be care. as yet in pits strong plants from the spring sowing may be carefully lifted and planted either in pits, or deep boxes or large pots, which last placed in an orchard house or vinery at rest will afford an acceptable supply in severe weather. It is quite as important an acceptable supply in severe weather. It is quite as important to keep up a supply of vegetables of the summer varieties as to have them early, therefore have protecting materials at hand in case of sudden frost. The season has been most unfavourable to ridge Cucumbers, Vegetable Marrows, and Tomatoes. In case of frost or even cold nights some light protective material thrown over them may so ward off its effects as to admit the supply being continued for some time yet. Tomatoes on walls have a fair crop of fruit; out them as they view. of fruit; cut them as they ripen.

Continue to prepare material for successional beds, making up one or more beds at intervals of three or four weeks so as to maintain an unbroken supply of this esteemed esculent. It is essential that the materials be put together with as little previous fermentation as possible, because fermentation induces decay. Spread the materials out in an open shed thinly and in small quantities, and though a slight warmth may be generated moisture will be dispelled. The best Mushroom beds are made up of about two-thirds horse droppings and one of short litter, which admits of slower decomposition, maintaining a steady heat. It is necessary to have a certain amount of moisture in the material, as when heating much moisture is evaporated, so that if too dry previously the heat will soon become exhausted from the want of sufficient moisture to continue the fermentation. Place the materials together as firmly as possible, insert good fresh spawn when the bed is at a temperature of 70° to 75°, earth with some rich loam, so moist as to form a firm surface, and when the Mushrooms appear keep the bed uniformly moist.

HARDY FRUIT GARDEN.

Wherever it may be intended to form plantations of young fruit trees the ground should now be prepared for their reception. The preparation will of course depend entirely upon the character of the soil and its underlying stratum. Soils resting on a heavy and retentive subsoil will require thorough and effective drainage, bearing in mind that the object of drainage is not so much the removal of water from the surface as to prevent its stagnation in the subsoil. Shallow drains are of no use; 3 feet should be a

minimum and 4 feet a maximum depth. The ground should be trenched about 2 feet deep, not bringing up too much of the unfavourable subsoil; but it is advisable to loosen the soil to a good depth. Old borders should have a considerable addition of fresh turfy loam, adding to those deficient of calcareous matter a tenth of chalk or old mortar rubbish; and when the soil is of a light sandy nature drainage may not be necessary, especially if the under stratum be gravel, but the surface soil should be enriched by a free admixture of fresh turfy loam, with preferably a free use of clayey loam or marl and a moderate amount of well-decayed manure. It is as yet too early for the planting of fruit trees, as the growth is unusually late, but it is well to have all in readiness for planting as soon as the trees are in a fit state to remove.

Orchard House.—The ventilators of this structure should be open whenever the weather is favourable, but in order to harden the sappy growths allow the temperature to rise to 70° or 75° with but moderate ventilation, and close early in the afternoon, admitting a little air before nightfall. It is of the greatest importance that the wood of all kinds of fruit trees should be thoroughly ripened; therefore all superfluous shoots should be at once cut out so as to admit as great an amount of light and air to the remaining spurs as possible. Except an occasional syringing to cleanse the trees of insect pests moisture overhead may be dispensed with, and moisture at the roots must only be afforded to keep the foliage in good condition.

Cucumbers.—The plants for winter fruiting should be planted as soon as ready. A good better heat is assertial to suppose whether

Cucumbers.—The plants for winter fruiting should be planted as soon as ready. A good bottom heat is essential to success whether it be obtained by the aid of fermenting materials or hot-water pipes; 80° being sufficiently high if from hot-water pipes, but a somewhat higher temperature is needed to commence with if fermenting materials are employed, as the heat will decline. The soil should consist of turfy loam, and for imparting vigour later on depend more on liquid manure than on giving it in the compost. Maintain a healthy and vigorous growth in the autumn-fruiting plants, being careful not to overcrop them. Secure a mean temperature of 75°, and gradually reduce the moisture as the days shorten and the heat declines. Add a little fresh compost about once a fortnight, applying weak liquid manure once or twice a week as may be necessary, fumigating moderately occasionally.

Melons.—The season as regards dung-heated pits and frames is

Melons.—The season as regards dung-heated pits and frames is about over, but where the fruits are still green and the plants healthy, linings of hot dung and night coverings will be necessary to insure their swelling off, cutting them when approaching ripening, and placing them in a warm and dry house. The weather is greatly in favour of late crops. Let the glass be kept clean, the foliage fairly thin so as to admit every ray of light, and afford no

more water than to prevent flagging.
PLANT HOUSES.

Greenhouse.—Zonal Pelargoniums that have been well grown and are stout and bushy should be placed in a light position in a house with a temperature of 50° to 55° with moderate ventilation, supplying liquid manure once or twice a week: they will be useful during winter. Cinerarias now advanced for flowering will require a temperature of 50° to 55° to enable them to expand the flowers well. Late Fuchsias should be encouraged by removing the seed pods as soon as the flowers have fallen, and affording weak liquid manure occasionally. Lachenalias should be potted so soon as they begin to grow, affording them light airy situations, and being careful to supply them with sufficient water. They do well in turfy loam with an admixture of leaf soil. Gladioli not yet flowered may be taken up and potted in 6-inch pots. Plants of Anemone vitifolia alba lifted with balls and potted will, if stood at the back of a south wall for a few days, soon recover, and being rull of flower and buds make a fine display in the greenhouse or conservatory for a long time. Schizostylis coccinea may also be lifted, and if well supplied with water will afford spikes for cutting over a lengthened period. Plants of Daphne indica set with buds may be introduced to a temperature of 50° by artificial means, and will come in at a time when very acceptable. Richardia (Calla) sthiopics planted out should be lifted and potted in 7 or 8-inch pots, and placed in a house of from 45° to 50°, introducing plants at intervals to a structure kept at 55° to 65°, by which means the spathes of these plants may be had for most of the winter. Heliotropes that have been grown on through the summer for winter flowering should have plenty of light and a temperature of about 50°. Primulas that were sown early and grown on through the summer in cold frames are now in flower, and should be near to the glass and be supplied with liquid manure occasionally. Shading in this structure should now be dispensed with, and the glass both inside and outside should be thoroughly cle

Admit air freely in favourable weather, and seek by every means to render the growth well hardened before winter.

TO CORRESPONDENTS.

* All correspondence should be directed either to "The Editors' or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

GARDENERS' EXAMINATIONS (Reader).—There are no examinations such as you refer to, now conducted by the Royal Horticultural Society.

SKELETONISING LEAVES (A Subscriber).—Mr. John Kaye, Hale, Cheshire, ablishes a small handbook on this subject, but we do not know the price

DRIED FLOWERS FOR BOUQUETS (R. J. W.).—Several species of Heli-chrysum, Gnaphalium, &c., are grown for the purpose you name, but the one you especially refer to is probably Helichrysum argenteum, a native of the you especially refer Cape of Good Hope.

BLUE BERRY AND BILBERRY (6. P.).—The Bilberry is Vaccinium Myrtillus, and the Blue Berry of Canada is Vaccinium pennsylvanicum, quite a different plant, which was introduced to this country in 1772.

BLACK CURRANT CUTTINGS (W. K.),—No better time can be chosen for inserting cuttings of Black Currants than immediately after the leaves have fallen from the bushes. Choose straight, sound, young shoots, making the cuttings about 15 inches long, and insert them firmly nearly half their length in the soil, 6 inches or more apart, in rows 18 inches asunder. It is very important to divest the cuttings of Bed Currants of all the buds except three or four at the top of each cutting, but we do not find it necessary to remove any buds from the cuttings of Black Currants.

IRISES IN POTS (H. S.).—The Irises you name will not force well, but they flower very well in pots when the plants are brought on gradually in cool frames or on a shelf in a light greenhouse. You may pot them the same as Hyacinths, and give them the same treatment generally, except that they will not endure the same amount of forcing, and will not flower until long after the Hyacinths have faded. long after the Hyacinths have faded.

long after the Hyacinths have faded.

VINE BORDER (T. S.).—Instead of making the border the entire width for the reception of young Vines, we prefer making it only 4 or 8 feet wide at the first, the front being supported with a wall of turves, increasing the width yearly as the roots extend and the Vines require more nourishment. Unless your border is concreted and well drained a brick wall will be of little use in confining the roots. As to the necessity for a wall, everything depends on the nature of the soil of the garden. We know of many good depends on the order. If you wish to confine the roots the border must be concreted, and the bricks forming the wall be laid in coment. If the subsoil is of a sandy or gravelly nature we should not use concrete; and if the Vines to be grown are Black Hamburghs and not required for early forcing, we should not build a wall provided the soil of the garden is fertile. We can generally manage to keep the roots "at bome" by placing a covering of rich manure on the surface of the border annually about October.

VINES UNFRUITFUL (L. R.).—First of all attend to the rods. If the

generally manage to keep the roots "at home" by placing a covering of rich manure on the surface of the border annually about October.

VINES UNFRUITFUL (L. R.).—First of all attend to the rods. If the spurs and laterals that produce the fruit are nearer to each other than 18 inches cut some of them out with a fine-toothed saw close to the main rods, afterwards paring the cuts smoothly with a sharp knife. Do this at ence, leaving the stronger laterals, which by the additional light and air admitted will mature their wood much better than if left crowded. At the winter pruning, which should be conducted immediately the leaves have fallen, do not prune too closely. Rather than prune back to the weak buds at the base of the laterals we would tie an occasional lateral up to the main rod and shorten it at the best and holdest bud where the wood is hard and brown. If you adopt this plan you will have far more side growths in the spring than you require; therefore, immediately you can see which promise to produce the best bunches, which will be when the shoots are about 3 inches long, remove all the others, leaving those for bearing the crop not closer than 18 inches apart up both sides of the rods. These laterals must have their tips pinched out two or three joints beyond each bunch, according as space is afforded for the free and unobstructed development of the leaves; but from near the base of each Vine select one good lateral and do not stop it, but train it up in as light a position as possible, letting it grow to the top of the house if it will do so. Now to the roots. Is the border well drained? if not, drain it. Is the soil inert? if so remove it and introduce fresh loam. Probably if you remove the surface soil, just barring the roots but not injuring them, and apply a sprinkling of burnt soil or charge of any kind placing on the leaves of the house of the house of the house of the sprinkling of burnt soil or charge of any kind placing on the leave approach of the house of the house of the house of the sprinkl introduce fresh learn. Probably if you remove the surface soil, just baring the roots but not injuring them, and apply a sprinkling of burnt soil or charred refuse of any kind, placing on this a heavy dressing of rich manure s or 6 inches in thickness, you would promote the emission of surface roots to the certain benefit of the Vines. This work should be done at once, never taking the manure off the border again, but allowing it to decay and become part of the soil. If you carry out these instructions and let us know the conditions of the Vines next autumn we will give you further advice, or sooner if you need it.

PRUNING VINES (A Subscriber).—If the canes are strong you may safely rune them so as to secure two laterals from each side of the rod and one leading shoot, the laterals not being from 15 to 18 inches apart. The Vines should be 3 feet 6 inches apart; if they are closer than this some of them may be left nearly their entire length, be borne heavily, and then removed. The wires ought to have been placed twice the distance from the glass, or 18 inches. Discontinue damping now, and employ fire heat in the daytime if necessary to maintain a dry atmosphere and warm temperature with abundant ventilation, but do not fire when the house is closed. The wood will then mature rapidly. Muscat of Alexandria will succeed in a house containing such varieties as Lady Downe's, Alicante, and Gros Colman, all of which thrive in a Muscat temperature.

SEEDLING BEIARS (Devorabire).—If you state the number you require to any good Rose nurseryman, informing him that you want them strong for budding next spring, he will supply what you require. Age is not a sufficient criterion of the condition of the Briars. You had better order them now and desire them to be sent as soon as they are ready, then plant them immediately in good and well-worked soil, mulching with manure.

WINTERING CARNATIONS (L, S, D).—All the choicer varieties should be potted as soon as the layers are rooted and be wintered in frames. If the pots are plunged in ashes or coocenut fibre refuse the frames will need no covering during the winter. The plants may be shaded slightly and the frames be kept rather close for a week or ten days, but afterwards too much air cannot be admitted during all favourable weather. The plants so wintered will be in fine condition for planting out in spring, or for growing in nots. in pots.

MILLIPEDES IN MANURE (Tyro).—We do not think the millipedes which you find in the manure applied to the Roses will injure the trees, still it is advisable to check their increase. The application of soot water applied as you propose would certainly benefit the Roses; and if it does not destroy the millipedes mix, by thorough agitation with a syringe, an ounce of parafin with a gallon of water and apply it to each tree, but try the soot water first.

PRACHES AND NECTABINES FOR A GLASS HOUSE (J. W. H.).—Peaches:

Barly Beatrice, Early Rivers, Rivers' Early York, Dr. Hogg, Grosse Mignonne,
Noblesse, Barrington, Walburton Admirable, and Lady Palmerston. Nectarrises: Lord Napler, Stanwick Elruge, Rivers' White, Pitmaston Orange,
Balgowan, Downton, Pine Apple, and Victoria.

LIGHT versus DARK FUGISHAS (J. Loss),—Mr. Cannell, who is good authority on Fuchsias, informs us that twenty-six or twenty-seven years ago when Mr. Storey raised Queen Victoria and Lady of the Lake, the question arose as to whether a Fuchsia with a white corolla and scarlet sepals should be placed in the "Light-coloured" class, and it was decided in the affirmative. As that decision has always been adhered to, the flower you have sent belongs to the "Light-variety" section. belongs to the "Light variety" section.

belongs to the "Light variety" section.

PROPAGATING ECHEVERIAB (J. A. X.).—Drain some pans or boxes well, and fill them with rough and very gritty soil; remove the offsets now with all the stem pessible, cutting off a lower leaf or two and any that are decayed, and let the wounds dry; then insert the offsets thinly in the boxes so as to leave a little space between each small plant. If the soil is moderately moist no water will be needed for a week or two. Place the boxes on a shelf in a light greenhouse or in a dry frame, and admit air freely. When water is applied let it be floated between the offsets, not sprinkled on them, so that it penetrates the entire mass of soil. Only water when the soil is dry, as excess is pernicious. Next May plant the offsets in rich soil in an open situation in the garden, and they will make fine plants by the autumn.

PROPAGATIME I CARBLIAS AND GERANIUMS (Lights)—If you wish two

open struction in the garden, and they will make fine plants by the autumn. PROPAGATING LOBELIAS AND GERANIUMS (Idem).—If you wish to preserve the old plants of Lobelias that are now forming green tufts, you must pot and place them in a frame, keeping them moist, and if needful shaded until they are established, then winter them on a shelf in the greenhouse. They will flower well early in the season, but will be no use for edging or bedding purposes, for which young plants are needed. To produce this divide the old plants, selecting some small tufts with roots on the stems, and insert them in light sandy soil in boxes. The tufts should be quite small and healthy, not drawn, and should be placed an inch or two apart in the boxes. With care in watering, and shading slightly when necessary, the boxes being placed in a frame for a time, and afterwards on a shelf in the greenhouse, you may preserve a good proportion of what you insert, which will form good plants by bedding-out time. The Geranium cuttings decayed because they were too warm, close, and moist. Insert short-jointed cuttings in gritty soil in well-drained pots, and place them on a shelf in the greenhouse, letting them have all the sun and air possible, watering only to keep the soil just moist. Most of the cuttings will strike, although many of the leaves will decay. When you apply water give it thoroughly.

PREE-GROWING EOSES (Idem).—Select the following from the varieties

FREE-GROWING ROSES (Idem).—Select the following from the varieties recommended by "BIGEPS" last week on page 244:—Capitaine Christy, Marie Baumann, Camille Bernardin, Dr. Andry, Duke of Edinburgh, Duchesse de Vallombrosa, Dupuy Jamain, Edonard Morren, Ferdinand de Lesseps, Justes Margottin, Lord Macaulay, Baronne de Rothschild, Madame C. Joigneaux, Madame Lacharme, Mdlle, Eugenie Verdier, Maréchal Vaillant, Etienne Levet, Prince Camille de Roban, Sénateur Vaisse, Victor Verdier, Gloire de Dijon, and Souventr de Malmaison.

PROPAGATING NEPENTHES (B. E. J., A Young Gardener).—Cuttings strike freely when inserted in the cocos-nut fibre refuse bed of a well-heated propagating house; but your safer plan will be to notch the growths as you propose, split a small pot and place it round each stem, and fill with turfy peat, sphagnum, and charcoal, and if this is kept moist and a brisk temperature maintained roots will soon take possession of the compost. Do not stop the flowering spikes of the Phalsenopsis.

CLERODENDRON BALFOURLANUM CULTURE (Idem).—Your chief object should be to have the growths thoroughly matured by affording all the light possible to the plant and some heat, not applying water too copiously at the roots. Winter the plant in a temperature of 50°. If you send \$\frac{1}{2}\text{d} in postage stamps to the publisher and ask him to send you No. 940 of the Journal, you will find an article from which you will obtain practical information on the culture of this plant.

POTTING LAPAGERIA (W. Johnson).—If the plant is quite healthy and growing freely you may repot it now, draining the pot thoroughly, employing a compost of very turty peat and turty loam, with a liberal admixture of crushed charcoal and sharp sand. If the plant is not growing freely we should not repot it until the spring.

DECAYED CHEESE (Old Subscriber).—Mix it thoroughly with earth or shes, and spread it over the plot where Cabbages are to be planted.

HEATING A GREENHOUSE (S. E. C.).—Undoubtedly the best mode of cating a greenhouse 15 by 12 feet is by using a small boiler and hot-water ipes. Two rows of 3-inch pipes would suffice if the house is a lean-to and pipes.

not greatly exposed. This mode of heating, too, is in the end not much more costly than other modes that are apparently more economical.

FORMING A ROSE GARDEN (Cottager).—We have known Roses much injured when growing contiguous to large brick kilns, and if the kilns are likely to increase we should not plant Roses largely until we found by experience, obtained by planting a limited number, that they would prosper. Your suggestion of alternate annual cropping of Roses and vegetables would be good were you growing plants for sale, otherwise the Roses may occupy the ground for three years before they are removed. The plants you name should be kept in a room from which frost is excluded, not a close warm spartment. They should be watered less copiously than in summer, but should not be permitted to become dust dry. Do not repot them until they show signs of fresh growth m the spring.

PORTUGAL LAUREL INJURED (A Constant Reader). — The injury is probably the result of the severe frost of last winter. We have seen many shrubs similarly injured. All you can do is to cut away the parts damaged, and by a little tying of the healthy branches you may perhaps preserve much of the uniformity of the specimen.

DIVIDING AND PLANTING PHLOXES (A. C. S.).—The plants may be divided and replanted with safety in October, and you may also purchase and plant young plants now for flowering next year. Ferns for the rookery we should obtain in pots and plant next spring, just as they commence throwing up young fronds.

GOOSEBERRIES AS ESPALIERS (J. Davies).—We have had no experience of the plan as a commercial mode of culture, but we have seen the system successfully adopted in private gardens. By planting in rows 6 feet apart and training the growths upright across wires you will certainly attain the objects specified—namely, increased fertility for manipulating both trees and fruit, greater facility for protecting the trees, and effect an economy in land by affording space between the rows for other crops.

PRIMULA ROSEA FROM SKED (R. Blanchard).— Plants can be readily raised from seed; indeed, we believe that Mr. Ware first betained his stock by that mode of increase, but we do not know if seed to offered for sale.

CELERY WITHERED (T.S. H.).—Your plants have been sewerely attacked by the Celery fly. See reply to "M. M." in last week's Journal, page 257. If all the leaves are as bad as those sent, your crop, we fear, will be of little value. You ought to have adopted remedial measures long ago. It is too late to restore the plants to vigour now.

FLOWERING SHRUES (E. C. K., Dublia).—Some of the best evergreen flowering shrubs are—Berberis Darwini, B. japonica, Mahonia Aquifolium, Helianthemum algarvanse, Ciskus angustifolium, C. purpurens, C. ladaniferus, Helianthemums, Ligustrum ovalifolium, Spartium junceum, S. multiflorum, S. Scoparium, Ulex europea flore-pleno, U. stricta, Viburnam Tinus, Vinca major, V. minor, Rhododendrous, Andromeda floribunda, Erica mediterranea, B. hibernica, E. berbacca, R. carnes, Kalmia angustifolius, L. latifolius, and Pernettya mucronata.

NAMES OF FRUITS (Mrs. Day).—If you will send us a bunch of Grapes firmly packed in wadding in a box so that it arrives in good condition, we will endeavour to mame the variety. Kerry berry of the bunch sent was smashed owing to the bunch being placed loosely in a tin box. (Q. C.).—The Apple is, we think, the Madeleine, known in some northern localities as the White Margaret. (R. Pulmer Williams).—It is the Cherry Plum the fruit of Frunus myrobalana. (W. Pottra).—I, Loan's Pearmain; 3, Braddick's Nonparell; 3, Not known. (W. B. Fisher).—The Necturine was quite rotten when it arrived. You should have sent some leaves also to assist in the identification. If you send again see that the fruit is not over-ripe. (George Suoles).—Wadhurst Pippin, certainly not London Pippin.

NAMES OF PLANTS (A. A.).—1, Passifiora Bellottii; 2, P. cerulea racemosa; 3, We think is Encomis punctata, but we cannot be certain without seeing a flower; 4, A Cupressus, probably C macrocarpa. (A. C.).—1, Phygellus capensis; 2, Eupatorium cannabinum; 3, Hibiscus syriacus var.; 4, Cotomeaster frigida; 5, Acacia dealbata; 6, Rhammus latifolius. (J. Howell).—The specimen is Platystemon californicum, an annual and a native of California. (G. O. S.).—Geranium molle. (Rosa).—Your plant is not an Orchidut an herbaceous plant, included in the natural order Melanthacea, and named Tricyttis hirta. It was discovered in Japan by the traveller Thumberg. (James).—The Fern is Gymnogramma chrysophylla, and the Begonia weltoniensis. It is impossible to name varieties of Coleuses from single leaves, or even from sprays, the varieties are so numerous and many of them so nearly alike that it is only by comparing plants with others in a large collection that the correct names of the varieties can be determined. (F. T. C.).—Eryngium campestre; Field Bryngo is the English name, a near ally of the Sea Holly, so common on our sandy seacoasts. (T. R. G.).—I, Sphresa callosa; 5, Clethra tomentosa; 6, Leycesteria formosa. (J. C., Amblesde).—1, Wilderingtonia cupressoides; 2, Thujopsis dollabrata; 3, Too withered for identification, perhaps Thuja orientalis var. compacta; 4, Retinospora obtusa; 5, Thuja orientalis (Chinese Arbor-Vitee); 6, Cupressus Lawsoniana fragrans. (Dixon).—1, Ascleplas curassavica; 2, Gymnogramma peruviana; 3, Pteris serrulata cristata; 4, Gymnogramma chrysophylla; 5, Rivina fore-pleno; 4, Polygonum orientale. (R. H. C.).—1, Recembles Francoa appendiculata; 2, Leycesteria formosa; 4, Euonymus europeus; 5, Sedum spectablie.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

DRAINING OF HEAVY LAND.

(Continued from page 259.)

In illustrating our practice of draining we shall next refer to a field of 14 acres upon a farm under our agency which we drained, and at the same time made a map of the work, showing every drain,

their depth and their outfalls, and this enabled us in after years to measure and find any drain which had become stopped. The home farmer will at once see the importance of draining being mapped, because under a change of managers or occupancy it would otherwise be extremely difficult to find the position of drains and their depth, and thus entail a serious expense in the event of repairs being required. The said field consisted of a strong clay with stones in it, but no veins of sand; the lower half of the field however, being more loamy, did not require the drains to be so thickly laid. The drains throughout were laid down the incline, there being a fall of about 20 feet from the top of the field to the lower end; the drains were laid with 2-inch pipes 86 feet apart, but the upper part of the field being the wettest, caused by surface water, the result of excessive rainfalls. These drains were intersected with others so that the strongest land was drained at 18 feet and the more friable part at 86 feet apart; the intersecting drains being connected with the others about half way down the field. At the lower part of the field these drains at 86 feet apart were connected with main drains of 8-inch pipes laid at right angles, each main relieving six drains by an outfall into the ditch, the object being to accumulate sufficient water at the outfalls to force and keep them clear, and this plan we prefer to each drain having its own outfall, either into the ditch or through the bank, as they are liable to become choked, but not so where a number of them go in the main drain with a single outfall. The connection of these drains by pipes is in our opinion an important matter, and instead of breaking a hole in the side of a main pipe for connecting a branch or a leader, we prefer what we call shouldered or angle pipes for the purpose, which are of two patterns, and can be obtained from most pipe manufacturers. Imperfect connections are then avoided, which often prove the cause of stoppages, &c. in cutting the drains in this field the work was accelerated considerably by using the plough to turn out two furrows on either side, so that the drains which were 8 feet deep were opened by the plough, and the soil loosened to the depth of 12 inches. We, however, wish to refer to the manner of digging out the drains; and because the ground was rather stony we did not like to depend upon the system of digging, whereby the cutting is made narrow enough at the bottom for the pipe to fit in the ordinary manner, but preferred to move the soil one spit wide at the bottom with one side made lower than the other, so that in filling in the earth its weight and pressure should effectually k eep the pipe in the position as laid on the lowest side. The soil having been moved wider at the bottom gave greater facility for catching the water and leading it into the pipe, but the principal object of the latter plan is to be able in stony clay land to make the floor of the drain quite smooth in order that the stones may not interfere with the laying of the pipes quite level. In the drains cut to fit the pipes they cannot so easily be laid exactly level, and when one pipe is out of the level by resting or partly resting on a stone it is often the cause of a stoppage, by the earth entering the pipe with the water. This is more especially the case with 1-inch pipes, and is one of the principal reasons why we prefer the 2-inch pipes, and reject the use of those of only 1 inch in diameter, for we have known hundreds of acres of draining become uscless entirely in consequence of using pipes of the smaller size.

In the field we have just alluded to the draining proved effective for many years, and until the death of the owner, when the estate was sold, and we gave up the agency. To continue our illustrations we will next refer to a field on the same estate of about 8 acres, the soil being a very stiff yellow clay but wishout stones, and injured only by the retention of surface water. We therefore in this case after digging holes in different parts of the field to thoroughly understand the nature of the soil, and digging a ditch all round it for the same purpose, as well as to obtain a sufficient outfall for the drains, we decided upon draining upon the plan, whereby the drain is cut as narrow as possible so as to move less earth and thus diminish the labour. In order that the drain may be made to fit the 2-inch pipe at the bottom it should not be wider than the outside diameter of the pipe. This field was so extremely flat as to be called table land, and there being no natural outfall

we were obliged to make two at both ends of the field and two at the sides by making the outfalls 4 feet deep. The main drains 3\frac{1}{2} feet deep, and the drains throughout 3 feet deep, were placed 16 feet apart, upon the principle of what is called thorough draining—that is, to lay the drains near enough together to draw off readily the whole of the surface water as quickly as possible.

We will now describe for the benefit of the home farmer, some and the proposed in these matters the tools required and

We will now describe for the benefit of the home farmer, some of whom may be novices in these matters, the tools required, and the method of cutting these narrow drains. The ordinary spades are of but little use for the work of draining in tenacious clays; we therefore employ the patent grafting tools first made by Mr. Lyndon of Birmingham about forty years ago. They are, however, now quite common, and can be easily obtained anywhere. These tools are thin and well plated with steel, and will enter readily into hard clays. The tep spit is easily removed; the two middle spits, however, are removed by a narrow three-quarter repade with a projecting iron for the foot, and the bottom spit is taken out by a long 14-inch spade with two cutting edges and an iron rest for the foot; this is used edge-ways first, and then removes a narrow but deep spit of earth, thus forming the bottom, the narrow scoop following for the removal of crumbs. The drain is then ready for receiving the pipes, having been made with suffithen ready for receiving the pipes, having been made with suffi-cient fall, which can be easily ascertained by a common carpenter's level. It must, however, be understood that the pipes cannot be placed by hand in such narrow drains; the drainers therefore use a piece of iron rod fixed in a handle and bent at right angles, on which they place the pipe and lower it into its place whilst standing astride on the top of the opening. The shape of this field was in length about double its width, and where a cross main drain was laid intersecting all the rest, with an outfall on either side, and with a main drain across either end, into which all the 3-feet drains emptied. The work was then quite complete, because there were in that case six outfalls all in operation at the same time, and each relieving a certain number of the ordinary drains, which, as before stated, were placed at 16 feet apart. The result of draining this stated, were placed at 16 feet apart. The result field was that it nearly doubled its letting value.

Our last illustration relating to the draining of heavy land was carried out upon a field of our own, and will exhibit in a remarkable manner the serious mistakes which may be made by drainers, and at the same time show the difference and value of the system of draining which now prevails compared with that in fashion at a more remote period. This piece of land contained about 5 acres, and when first we became possessed of it was in pasture, and about as worthless a meadow as could well be seen except about 1 acre, which was dry and very productive. The subsoil was of rather a strong clay with some veins of sand in it, and had been drained formerly with gravel drains for removing the surface water. They had, however, become stopped, and the meadow was so hopelessly wet and the herbage so sour and coarse that we decided upon breaking it up and converting it into arable, in order that it may be and also that we may the better be enabled to see how it should be drained. Although the general surface of the field was a clay soil, yet there was a bird's eye spring in it with a quicksand at bottom, so that we could run a pole down for a depth of 12 or 14 feet. This we relieved by a drain, but the great mistake we made in laying out the drains in this piece of land was a dis-regard of the quicksand spring, for this ought to have shown us, as it eventually d.d, that although the land was a strong clay at the top that it might be made wet in consequence of water lying deep in the subsoil. In our inexperience, however, at that time we disregarded this matter, and proceeded upon the plan of thorough draining the land with pipe-drains at 16 feet apart and 2 feet in depth. It was found, however, after several years that the drains were comparatively inoperative, and the land too wet for profitable culture. It, however, eventually occurred to us that the land must be made wet by the water rising from a considerable depth through the veins of sand, worm holes, &c., to the surface, and in order to test this a deep hole was dug, and a quicksand bottom found at the depth of 12 feet. Now this fact proved a solution of the whole question of the surface soil and in consider the whole question of wetness of the surface soil, and in considering the position of this field which had a fall of only a few feet at the upper end, yet in the lower part it had a sudden fall of 20 feet down to a brook. We therefore decided to make the brook the outfall of a deep drain, and in cutting it on entering the hill we found a deep body of impenetrable clay, which was the cause of the quicksands having no outlet, and in consequence the water rose to the surface as above stated. This deep drain which was laid 12 feet deep was a very heavy expense, but it proved a good outlay notwithstanding, for after it was finished the field continued to this day a fertile soil. The manner of cutting this drain and the difficulties we had to contend with will at a future time be explained under the heading of deep or spring draining in this Journal.

WORK ON THE HOME FARM.

Horse Labour.-The harvest, not yet being completed in the late districts, will still employ some of the horses; but at all times when they can be spared from harvest carting, dc., they should be employed in carting out manure on to the land intended for wheat, doing the fallow break first, for upon the lea ground

this work may be carried out even after heavy rains. Autumn tillage of land intended for roots next year should now have been tillage or land intended for roots next year anouth now have occur
completed, or nearly so. In the event, however, of the weather
being favourable much may be done in a short time if the steam
cultivator is employed, the horse following close behind dragging,
harrowing, rolling, dc., until the couch and weeds are so far separated from the soil that they may be carted away. Our plan is never
to burn any vegetable matters that will decay in a heap, because
it will always furnish useful manure, especially for pasture land;
header the certing to heap can be done when the weather is not dry besides, the carting to heap can be done when the weather is not dry enough for burning. Immediately the antumn tillage is done the work of preparing the land for wheat should be forwarded. The best time for sowing the land with wheat, when it is well manured and otherwise in good condition, is from the middle of October to the middle of the month of November upon all dry healthy land, but upon cold hilly land in various parts of the country should be sown about a fortnight earlier. In ploughing and pressing the land out of clover lea this may be done where horses of sufficient size and power are kept, with two horses drawing a double furrow plough, and the presser following behind. This work is also done well now by most of the steam ploughing sets. We saw much work done by them last year in a very satisfactory manner, and in all cases where the work of the home farm is in arrear it may be soon brought up with the time of the year by steam power. Should the farm horses be laid up in the stables from disease or illness—such as influenza, which we have some-times known to be the case—steam power is the only plan to prevent the seed time being lost, as every farmer is so busy at such periods that generally no horses can be hired. The quantity of seed per acre is still a vexed question, varying between 1½ to 2 bushels per acre; but we consider it should be dependant upon the time of year, the state and condition of the land, and also the variety, for some varieties will tiller out much more than others, and thus fill

up vacancies which may occur accidentally.

Hand Labour.—The men, when they have not work in the harvest field, will now be employed in filling the manure carts, and spreading after it is laid out, and this work is, we notice, often very imperfectly done. In those cases where manure is not properly separated it is not so effective, as the wheat will then grow in irregular bunches instead of growing with that evenness which is so essential to the production of full crops of both straw and grain. At odd times the hedge trimming will have been done during the late showery weather, but if not completed the sooner it is done the better, before the new wood gets hard and wiry. We have not seen the new hedge clippers in use yet, but the hedge-trimming machine drawn by a horse may answer where the fence is of quickset, and without a bank and ditch. Neither have we seen the hand-clipping machines at work, but we think they are more adapted for ornamental hedges under the care of the gardener than for the ordinary hedges of the home farm, for unless they have been extremely well kept previously any old hard wood left would seriously impede the use of the hand-clipper, in which case it would probably not get through so much work as the old-fashioned trimming hook. Late-sown turnips will require to be hoed, and in some cases the early sown roots will require further attention by hand-hoeing again, the season having been so wet. Numerous fields of roots, although hoed at the usual period, wet. Numerous fields of roots, although hoed at the usual period, require to be looked over again, as the grass and weeds have not died after hoeing as they do in ordinary seasons. The time is now arrived for the purchase of sheep for the winter's stock, and as they are cheap this year it may be well to lay in a full stock, at least if the provision is sufficient in roots, hay, &c., nor are feeding stuffs likely to be dear; the number of sheep in the kingdom is short, and in consequence mutton is likely to make a good price in the spring of next weer. A less number of bulleyls will probably the spring of next year. A less number of bullocks will probably be fed this year, as the root crop is backward and the bulbs small, and better adapted for sheep feeding on the land than for cattle in the boxes. In buying sheep the home farmer should be sure to take a warranty of soundness, as so many are affected with the rot, with flukes in the liver, which are now being slaughtered by the butchers. The dairy cows will now demand the attention of the home farmer, as the grass is getting short in many cases; it will then be well to give them cabbages distributed on the grass land, for nothing can excuse the home farmer if he has not a good crop of cabbages now available for cattle feeding. Rye and winter tares mixed with winter oats should now be sown, and the land should be got ready for drilling winter beans, and to manure for them lay out yard dung and plough-in, otherwise sow 4 cwt. of dissolved bones per acre and harrow-in at the time of drilling, or else sow them immediately behind the drill and harrow-in. Winter Chevalier barley, much approved of in Wittshire and other counties, may soon be sown, as it stands well through an ordinary winter, and produces an early crop of the finest quality of malting grain. The ordinary winter barley may now be sown also.

CANARY TREATMENT .- No. 7.

In my last chapter I remarked upon the points and difference of appearance between the London Fancy and Lizard breeds of the Canary compared with other kinds. Speaking of Canaries in general I may state that the young of such soon after they are chipped give evidence as to whether they will be clear or variegated. If of the latter kind the skin will show dark patches here and there, but if the young appear flesh-coloured throughout they will almost to a certainty become clothed with a clear plumage, or at the most be only slightly ticked in their feathers. The above remarks refer more particularly to the Belgian, Yorkshire, and Norwich breeds. Upon this point I have entirely convinced myself.

Even-marked birds are the most difficult to obtain, those most in fashion possessing the much-coveted spectacle-eye marks, and the dark lesser flight feathers. As to the eye-marking, the skin of the newly-chipped birds will appear somewhat dark, but respecting the wings our curiosity is somewhat held back for a few days until the pin feathers begin to form in the wings. Then upon minutely casting your eyes along the joints of each wing you may perceive one part light or flesh-coloured, and the remainder dark, and although the young may be but three or four days old you can at once decide whether there will be anything or not of a promising kind. Upon the young bird attaining more age and developing its plumage, if fortune should favour you, exercise patience and debar yourself with as little prying into the nest as possible, or your hopes of rearing and moulting, and realising a good sale price for the bird will be at once blighted. Even-marked Canaries are valuable, and I have known many to have been sold at exhibitions for £5 or £10 each. As with Dutch Rabbits, with which I have also had some experience, there is quite as much curiosity evinced as there is with Even-marked Canaries.

Perseverance and patience, without which not much good will be effected, should be the guiding rule of all who enter into Canary breeding, especially if they breed for Even-marked Canaries for exhibition. Most fanciers prefer to breed from Even-marked parents, and certainly we look at such with more pride than those birds marked anyhow and anywhere. Still there is little chance of the young from Even-marked birds being so marked. Clear and Uneven-marked birds can be bred in abundance, but such have not so much to commend them for prizes as those more

favoured with the so-much-prided marks.

Newly-chipped Canaries of the Cinnamon breed present a deeper flesh-coloured hue of skin, besides possessing the marked characteristic pink-coloured appearance about the covering of the eyes before attaining the sight, and even afterwards the eyeball presents a pink transparent appearance different from other Canaries. Cinnamon Canaries, somewhat like the Lizard birds in their earliest days of life as to colour of skin, soon show forth their general characteristic appearance when their feathers begin to bud. If any of the young should possess a foul feather it can be easily seen. This breed is frequently crossed with Norwich or Yorkshire birds for the object of obtaining marked and high-coloured specimens, and are likewise crossed with created birds.—G. J. Barnesbr.

VARIETIES.

At the Poultry and Pigeon Show to be held at Merthyr Tydfil on October 8th and 9th the classification for poultry is very good. Cocks and hens of most breeds are to be shown separately. There are three prizes for each class of 30s., 15s., and 10s. There are ten classes for Pigeons with two prizes in each. The entry fees are very moderate—viz., 4s. for poultry and 2s. 6d. for Pigeons.

— MR. O. E. CRESSWELL asks us to state that he is, as usual, requested to collect subscriptions towards a cup for adult Silver-Grey Dorkings at the Crystal Palace Show. It will save much trouble if those who wish to subscribe will kindly send their subscriptions to his address pro tem., Bangor Lodge, Sunninghill, Berks.

The schedule of the Oxford Show to be held on October 22nd and 23rd is also before us. There are considerable changes in the Committee, none of whom will exhibit. There are special classes for local exhibitors in lieu of special local prizes in the general classes. We do not see much change in the general arrangement of the schedule. The first prizes for poultry are in most classes £3. Why White and Cuckoo Dorkings, which have generally been well represented at this Show, should have only a £2 first prize between them we do not know. As usual at Oxford, Black-breasted Red Game are well cared for, the first prize for both cockerels and pullets being £5. There is a class for undubbed Game cockerels, and a special prize for the best unskinned Game cockerel in the other classes. Silkies disappear from the list. We regret this, for Oxford was the first show at which a class was ever given to the variety, and all the best specimens of it that we have ever seen were collected in the Oxford Corn Exchange. They are pretty as pets and useful for rearing Game and small poultry. Sultans seem taking their place as fancy birds. In Pigeons Dragoons come in for the lion's share of honours with fifteen classes for every imaginable subvariety, and over £26 in prizes. An immense number of entries must be expected, for £150 would only pay the prize money. There will not this year be a special day devoted to judging, but the staff of Judges having been increased the

awards will be made on the first day of exhibition. The Judges appointed are for poultry Mr. E. Hewitt, Mr. R. Teebay, Mr. J. Martin, Mr. G. S. Sainsbury (Waterfowl); for Pigeons Mr. F. C. Esquilant, Mr. P. H. Jones, Mr. H. Allsop, and Capt. Norman Hill. There are four classes for dead poultry, which will be judged by expert poulterers.

— WE have received a small pamplet entitled "British Song Birds—a Practical Guide for Fanciers," by Richard B. Ladley, and published by John Heywood, Manchester and London, that contains some information on the management of the brown linnet, the skylark, the woodlark, the bullfinch, the goldfinch, the canary, the chaffinch, the thrush, the robin, the blackbird, the nightingale, the titlark, the siskin, and the chitty or greybob. The author remarks in the preface that "he has been a bird fancier for thirty years, and during that time has had extensive experience as to the manner of keeping, treating, and breeding British birds. Several writers, when dealing with song birds, merely describe the plumage, peculiarities, &c., but never touch on the food necessary to keep birds in good condition and song. Many good birds are thus lost because people know little or nothing of the treatment required, and when the birds are ill there is no remedy suggested to restore them. The necessary treatment required by each bird is stated, and by simply following the instructions given the birds will be kept in health and song." The instructions given are plain and clear, and the cheap little pamphlet will probably be largely distributed.

— Homing Pigeons have lately been made useful in a new fashion. The Trimby Corporation is now employing them for communication between the lightships and the land near Harwich. On Wednesday 24th two homers arrived in the town, bringing messages to the effect that a vessel was in distress near a lightship, and a lifeboat was immediately sent to the rescue.

— THE next meeting of the Poultry Club will be held during the time of the Dairy Show in the Agricultural Hall.

— Clubs of the fanciers of special varieties of poultry seem becoming common. About three years ago a Game Club was started, but we fancy made little progress; then the Leghorn Club under the auspices of Mr. A. Kitchen arose and flourished, and has done much to popularise its speciality. The Langshan admirers, too, are bound together in a fraternity with common objects; and we observe in the Oxford schedule that the first prize for Sultans is presented by the Sultan Club.

— We have lately seen many very forward and well-matured chickens of the year. Though the early months were so unpropitious the abundance of insect food from the wet summer seems quite to have compensated for the check to growth from the spring winds and frosts.

— The Lincolnshire Bee-keepers' Association's fourth exhibition, in conjunction with the Long Sutton Agricultural Society's Show, will be held on October 8th and 9th. £50 is offered in prizes, with the Association's silver cup and special prizes for labourers, and there will be the usual manipulations by skilled apiarians. Mr. R. R. Godfrey, Grantham, is the Hon. Secretary of the Association.

TREATMENT.

FOUL BROOD, ITS NATURE, APPEARANCE, OURABILITY, AND

That apiculture is now attracting more attention than it has received for many past years none acquainted with the history of the subject will deny. That it has advanced with giant strides through the introduction of foundations, the extractor, and other appliances that would make a long catalogue, is equally apparent; and yet amidst all this pleasant prospect, seeming to promise greater things for the future, a dark cloud—causing most to fear, and even breeding despondency in the breasts of not a few apiarians—is hovering amongst us. I allude to the existence and spread of the fell disorder foul brood. With the idea of diffusing and establishing the belief that this disease is understood on the one hand and curable on the other, so that well-founded hope may displace despair, and active measures for its annihilation be taken where it exists, I address myself again to this subject, and give a singular corroboration of our knowledge of the nature of the disease which has just occurred in connection with this Journal.

Not long since a piece of super comb containing three small brown specks was sent to Fleet Street in a little box through the post, accompanied by a request that we should determine whether it was contaminated by foul brood. The practised hand of the postmaster had applied the stamp with vigour, and the specimen was so crushed that nothing could be made of it by unassisted vision. The nose applied to the brown parts when freed from honey seemed to indicate foul brood, the nauseous smell of which (we are writing for practical, not fastidious people) is not unlike the odour of extremely dirty socks, this odour being usually very strong in infected hives, but by no means invariably so. The

microscope had now to resolve the difficulty, and by the use of an eighth objective and a deep eye piece the micrococcus germs, the immediate cause of the disease, were found in tens of thousands in a speck of the brown substance diffused in a little water. The erms were accompanied by minute fibrillse, as shown in the wellknown Italian diagrams. The case was clear. The hive from which this super had been taken was foul-broody, and we so advised our correspondent, from whom we received a letter stating that a similar specimen had been sent to another authority, who had replied, "There is no sign of foul brood, but there are evidences of brood having been raised in it, and there is a little pollen which adds to the discolouration." We reasserted our position that the hive was undoubtedly foul-broody, for had we not seen the disease? But in order that all doubt might be renot seen the disease? But in order that all doubt might be removed we paid a visit to our esteemed correspondent's apiary, and there found the fullest confirmation of our position, for the hive pointed out to us in the absence of the owner as furnishing the super from which the part in question came was actually dying out from the advancing disease. The wrong hive, however, had out from the advancing disease. The wrong nive, nowever, not been shown us; so a second visit became necessary, when we again met foul brood as in the previous case, though in a less advanced condition. The brown matter was not like pollen in our opinion to the eye, but under the microscope micrococcus is no more mis-takeable for pollen than heaps of loaves for heaps of dust shot. This episode in the first place establishes our knowledge of the nature of the disease, since its presence was detected, not by looking at combs half filled with rottenness or examining decaying grubs, but by discovering the presence of the cause of the disorder—the micrococcus, which, by growing in the body of the larva as yeast grows in rising dough, soon delivers it over to death and decomposition. It may be asked, Although this microscopic examination is interesting, is it ever likely to be useful? The answer is undoubtedly Yes, and a case in point has been given; for had our opinion not been asked we take it that our correspondent's apiary would have been ravaged if not ruined by the disease before he had become sufficiently alive to its presence to have taken measures for its suppression. But beyond such cases brood not unfrequently dies from chill, and is known by the name of chilled brood, the appearance of which is so like to foul brood that the merely practical man would often be quite unable to determine whether the before-mentioned disease was present or not. Every bee-keeper of experience has met this puzzle, which the microscope bee-keeper of experience has met this puzzle, which the microscope alone can resolve. With the exception just mentioned the appearance of infected combs, if the disease has made any progress, is so characteristic that all but the merest tyro could pronounce upon it. In looking into a card of unsealed grubs, which while healthy are all of pearly whiteness, one here and another there may be noted of a yellowish sickly tone, and these usually—instead of being posed as Swammerdam says, "curled up at the bottom of the cell like a dog asleep"—are thrusting their heads forward toward the cell mouth. This indication is very marked in unsealed brood. These grubs sometimes die before the period of sealing, and their bodies, as experiment has proved, are occasionally removed by the bees and dropped at a distance from or sealing, and their bodies, as experiment has proved, are occasionally removed by the bees and dropped at a distance from the hive; but more generally they pass through the phases of decomposition, shrinking and turning brown, while the water continues evaporating until nothing remains but a blackish brown scale on the lower side of the cells. It is in this condition that they become the infectors of the rest of the hive, for now the minute germs of the micrococcus are given off in immense numbers, minute germs of the micrococcus are given off in immense numbers, and flying through the hive find their way into every part. Other grubs are attacked until the exhalations from the dead nauseate and dispirit the whole population. The fanning at the door carries out these germs in myriads, which are thus diffused, to be taken with the indraught into neighbouring colonies. The complex hairs of the bodies of the workers must hold them in their meshes, and in fact in every correct of the aniary will scon live these and in fact in every corner of the apiary will soon lurk these minute possible ministers of death and destruction. But many of the grubs do not die until after they have been sealed, and so in inspecting an attacked comb we shall notice that the patches in inspecting an attacked comb we shall notice that the patches of sealed brood are very irregular in colour. Each darker cover lying over the coffin, and not the cradle of a young bee; others, which conceal the bodies of those long since dead, will be pierced by irregular holes, and the cover, instead of being convex, will be sunken and rather glossy instead of dull in surface. When the covers are removed the rotten remains brown, fetid in odour, and covered the total property of the covers are removed the rotten remains brown, fetid in odour, and so viscid that they may be drawn out in threads like treacle will be discovered. With this description the owners of frame hives need have no doubts, except the suspicion of chilled brood, for which some explaining cause can always be assigned.

To the ideas of Mr. Pettigrew, as expressed by him in the Journal of June 19th, I have previously taken exception, but did not refer to the general sweep of his opinions respecting the carry-

not refer to the general sweep of his opinions respecting the carrying of the disease by the bees, and from which, if I understand him aright, I dissent in the most absolute manner. I quite agree with his fact when he says, "We have known swarms leave the disease behind them and thrive well in new hives;" but his implied inference is most dangerous, especially when coupled with the remark, "We have never known swarms from diseased hives carry the disease or germs of the disease with them." If this be

a general truth it is honest in a dealer to take a swarm from a hive saturated with micrococcus, and send it into a healthy district. On the contrary, I agree with the Editor of the American "Bee Journal" that "it is criminal." Swarms from diseased hives may do well themselves, and yet infect the district into which they have gone, for reasons that ought to be apparent. The first of their brood may in a few cases get infected from germs carried about their bodies, and yet by the removal of the dead, as previously explained, the disease will be eradicated. Experiment has shown that introducing spores into hives does not in the greater number of instances from this reason establish the disease.

The curability of foul brood is the next point upon which I wish to insist. While we feel sure that the doctor can do us no good we will not take his medicine, and while bee-keepers believe that foul brood must run its course and work out devastation and ruin nothing will be done to arrest it. I assert its curability because I have again and again cured it, and in this position I am pleased to be able to refer to one of the most prominent, certainly one of the most scientific and successful, apiarians of our day one of the most scientific and successful, apiarians of our day—T. W. Cowan, Rsq., Chairman of the Committee of the British Bee-keepers' Association, whose experience in the treatment of this malady has been great, but not greater than it has been successful. Mr. Cowan, in reply to a request that he would permit a publication of his methods, has favoured me with a lengthened letter in which he says—"I am quite, I think, of your opinion as regards foul brood, that it is to be cured if attacked in earnest. You know I had it in my apiary, and it was a source of great trouble to me, but I stamped it out with salicylic acid. My prooeeding was to excise any very bad places, and when I found cells affected here and there I merely uncapped them and sprayed the combs with the solution of which I send you the recipe. I found generally in mild cases one application was sufficient, but in more severe ones two or three doses produced a complete cure. I found that if the cells were uncapped before they were punctured and sprayed with the solution, injecting a larger quantity into the affected cell so as to eject the viscid mass, there was no fear of the disease appearing again. In this state the viscid fluid in the cell is of a light brown, and is not permeated with spores to such an extent as when it is allowed to remain until it becomes highly coloured and the covering much depressed. I doubt very highly coloured and the covering much depressed. I doubt very much if in this stage it is very contagious. I have no doubt the acid acts on the spores and destroys their vitality. So far so good. Now as regards the honey that is in the hive and which is supposed to contain the spores (although I must say I have never been able to detect any by the microscope), how are we to ensure their being destroyed? Simply by uncapping it and feeding the bees on syrup containing the acid, which they will store with the uncapped honey, or uncap it and give it a good spraying with the acid solution. I have done both, but cannot say if it was really required; but as I think prevention is better than cure and really required; but as I think prevention is better than cure, and

"All my hives are scalded, and so is everything that has had anything to do with the hive, and afterwards everything is washed over with the solution. I believe the germs of the disease are carried in the air, and we can never feel safe; I therefore always put acid in all the food I prepare. I examined six of my hives and all were healthy but one, and that I thought was also healthy. It was an early swarm. This year I had thrown off a swarm and a cast, and had given me six small 1 lb. sections nicely filled. looked on the ten frames and found no queen and no brood. There was one cell covered but not punctured, but I at once recognised it as a foul-broody one. Now the hive had not been queenless very long, as about ten days ago I saw the queen, and although she was not laying there was a small quantity of brood betabling out and all did batch our transact this one cell, it was hatching out, and all did hatch out except this one cell; it was uncapped and injected with the solution, and the other combs and bees sprayed with it. I have no doubt it will prevent its spreading in the future, as I shall not hesitate in using these combs in uniting if I require them.

mining if I require them.

"I have examined six hives to-day, fearing to find foul brood, but have not detected a single cell in any of the other hives. Now, how did this appear? It seems to me probable that it was brought there by some of the bees from outside, or a spore might have been lurking in some of the corners of the hive and had escaped the solution. This proves to me that it is impossible to tell when it may break out in an apiary; and as we know from experience that salicylic acid destroys the spores, I think it not only beneficial but important that a certain quantity of this acid should be in all the food given to the bees. Two years ago I tried feeding the bees on syrup containing a strong dose of acid without spraying the combe, and I found that the disease gave way to this treatment; but I find the other plan, that of uncapping and spraying, the most rapid. I do not mean to say if a hive is neglected, so that all the brood is rotten, it can be cured; but if taken in time, as every apiarian would do, it has been and can be cured.—Thos. WM. Cowan."

The table of recipes Mr. Cowan encloses will explain themselves.

Salicylic acid solution for mixing with syrup for feeding bees,

painting over hives, and spraying combs, &c., for the prevention

Salicylic acid	1 oz.
Soda borax	1 oz.
Water	4 pints.

Spring and summer food for bees :-

White lump sugar	10 lbs.
Water	7 pints.
Vinegar	1 oz.
Vinegar	1 oz.
Balt	d oz.
D-D don a dom orderator	¥

Autumn and winter food for bees :-

White lump sugar	10 lbs.
Water	5 pints.
Vinegar	1 oz.
Salicylic acid solution	1 05.
Salt	₫ 08.
Dell day a farm minutes	-

Some remarks upon the action of salicylic acid, and the plans I have myself followed, I must reserve, through pressure of space, till next issue.—F. CHESHIRE, Avenue House, Acton, W.

OUR LETTER BOX.

KERRY Cows (H. B.).—We do not know any place in the midlands where you can get Kerry Cows, but if you wish for any and you will send your address, we can recommend you where to get them.

address, we can recommend you where to get them.

GOBSE CULTURE (Hussingdonshire).—Gorse will grow very well upon cold clay soils if the land is rather hilly and sheltered by woods, plantations, &c.; if, however, the land lies flat, and has not been drained, the ground should be clean fallowed and laid into ridges 5 feet wide, with land and water furrows properly made for the drainage of surface water. Seed may then be drilled or plants set, as stated in the Journal September 18th, at page 239, on the subject of cultivation and usage of gorse. If the land is very poor and in low condition 3 owt. of dissolved bones mixed with rough coarse ashes may be strewed over before ploughing into ridges, or into the furrow before planting, and the land should be kept clean by hosing until the plants have covered the ground, and thus prevent the weeds from injuring, which they will do as much as if the crop was mangold or turnies. The crow the plants have covered the ground, and thus prevent the weeds from injuring, which they will do as much as if the crop was mangold or turnips. The crop will then be fit for cutting in November. The cutting of the gorse should be done daily like other green crops such as vetches for current use and pulped immediately, for its will not keep but turn sour if not used directly. Nor is there any mode whereby it can be out, dried, and preserved like hay, because it is only cut and used in the winter months when the weather is adverse for storing in rick or otherwise, supposing it could be done; but gorse cannot be used to advantage without being pulped with Mackenzie's Masticator, all the former methods of reducing it by the chaff cutter, &c. may now be given up as useless. Any field of gorse must be fenced and protected from the bite and spoil of cattle during growth. It is likely to pay more money than the growth of cereals upon cold clay land, and if the value of cereals should ever make them worth growing in the future upon such soils the gorse land would prove very productive on being broken up, and would be found permanently improved for the production of other crops. Grove.

PRICKLY COMPARY (T. R. G.).—Symphytum asperrimum is the botanical name of the plant to which you allude. It should be grown in deep highly manured soil, and though it is quite hardy a good covering of manure placed round the crowns in winter is very beneficial, the manure in the spring being pointed in with a fork. Prickly Comfrey cannot be grown too quickly, for if grown slowly by lack of nonrishment it is apt to be bitter; cattle do not always eat it readily at the first, but they generally soon "take to it," eat it freely, and thrive well.

eat it freely, and thrive well.

SUGAR FEBDING FOR BEBS.—F. J. asks ff a slice of sawn loaf sugar an inch thick or so would do instead of barleysugar for extra feed for winter if placed under the quilt. The answer is No. Loaf sugar is not diliquescent, and bees are unable to appropriate it, except in such small quantities and at so much labour as to make it practically useless. This you can prove thus: If you feed with condensed honey the honey crystals will be perfectly cleaned from all moisture, but will remain untouched however pressed the bees may be; and, again, bees will starve with abundance of crystals of either sugarfeed or honey-sugar in their cells.

SUSPECTED FOILS BROOM (I. S. Commiss.) We form the same condenses
BUSPECTED FOUL BROOD (J. S. Catrate).—We fear from your description that your suspicions are correct, and that your hive is foul-broofy. If the hive is strong in bees you may attempt its cure with a good chance of saving it, but we would in no case recommend it being joined to another that you believe to be healthy. If you would like to feed the bees with symp containing salicylic acid and find a difficulty in obtaining the latter Mr. Cheshire will send a small quantity if you send a stamped directed envelope to this office.

GRUES OF WAX MOTH IN HIVES (L. L. K.).—The larve are, as we supposed from an inspection of the trails previously sent, those of the wax moths, either Galleria medionella or Achroia grisilla. The mother moths seek access to the hives during the nights of the warmer weather; but soarcely succeed except in those that are vary weak. The eggs are then deposited on the combs, while the tiny grubs hatching therefrom feed upon the wax, boring through the middle of the waxen cell work and spinning as they advance a tubular web, which the bess so much dislike that they only remove it by biting out the surrounding comb and letting it fall. If many of these craphs are at work they seed destroy the comb so utlerly that its wreck dross it by biting out the surrounding come and letting it rail. It many of these grubs are at work they soon destroy the comb so utterly that its wreck drops bodily, grubs and all, on to the floorboard. If the hive is very weak in bees and the moth has strong hold measures ought to be taken, but if the bees are numerous they will make hereafter proper repairs. Combs left without bees are often totally destroyed by these poests. The mass the box contained consisted of wax plates dropped during comb building, the tubular webs previously referred to and the dejectaments of the larva looking like grains of composite. of gunpowder.

whether she has mated. A virgin queen is usually very shy and hides amongst the bees, but this is at best a most uncertain indication. Put your frames into a small hive or confine your bees by a division board to a space they are well able to fill, and continue to feed gently. If in three or four days no eggs are found we should without hesitation destroy the queen.

cays no eggs are found we should without hesitation destroy the queen.

INTRODUCING LIGURIAN QUEEN (Idem).—We often introduce Italian queens later than now, but if the process be unsuccessful and the failure be nunoticed, the hive is doomed. If a hive has been long queenless, or, which is the same thing in this respect, had for long a barren queen, it is usually better to unite it to another for two reasons. First, the bees are old and will not survive in sufficient numbers to keep the hive in good order up to spring, and the queen's progeny cannot be reakoned upon, as not very much brood will now be raised; and secondly, the bees being old will only accept a queen with much persuasion, and may even reject the profiered mother in spite of every effort.

BERS AT THE MOORS (*Idem*).—Bees will hardly now improve at the moors in any locality. We should set them at once on their winter stands, and see to making all snug, feeding them or not according to circumstances.

THE BRE THRT (A Suberfor).—The bee tent has not been overlooked, since a description was given of it in our issue of June 36th last. Driving or drumming has been one of the grincipal features of the manipulations during the past summer, and this operation will be made the subject of an article in a few weeks.

WINTERING SERPS (H. C., Tramfeld).—You may bung the top hole, but by no means stop every fraction of ventilation round the edge by fixing down to the floorboard with clay or mortar. Reduce the mouth somewhat, but do not make it less than 1 inch long by \(\frac{1}{2} \) inch high.

REMARKS.

Ath.—Unsettled morning though with a good deal of sun; sudden storm at 010 P.M. with thunder, hall, and heavy rain, 024 inches in ten minutes; bright sunshine again by 0.38 P.M.; one or two heavy showers in afternoon; fair evening.

showers in arceroom; fair evening.

25th.—Fine bright day throughout.

26th.—Fine bright day; slight showers in evening.

27th.—Rather dull in morning; fine bright afternoon.

28th.—Fair morning; gusty wind in the middle of the day; rather dull in afternoon; wet evening.

29th.—Slight drizzle in first part of morning, afterwards fair but not very bright.

Soth.—Rather cloudy, but on the whole fair.

A week of fine but rather cool weather, all the thermometric means with the exception of the maximum in sun being several degrees below those of last week; the mean of the barometer readings is rather higher than last week.—G. J. SYMONS.

COVERT GARDEN MARKET .-- OCTOBER 1.

Now the fresh fruit is nearly over our market assumes a quiet aspect, and the little outdoor stuff reaching us is far from satisfactory. A good many house Grapes are now being sent into the market, causing values to be low.

From observations taken near London during forty-three years, the average day temperature of the week is 60.4°; and its night temperature 41.8°.

VINES IN POTS.

N page 223 Mr. Smith, with the help of Mr. Miller, gives a very lucid description of the method of quickly raising a stock of pot Vines, successfully adopted by the latter. Mr. Smith also invites a further discussion on the more extended cultivation of the Grape Vine. The subject is not only generally interesting, but most important; consequently every fresh advance (which Mr. Miller's practice has every appearance of being) is readily welcomed by the readers of this Journal. No doubt unfavourable

criticisms will be passed on it. I for one, in a discussion with a practical friend, having argued against it, I put what I thought a "ticklish" question when I asked, Where in an established vinery are we to place a plank bearing a number of 10-inch pots, seeing that the young Vines must not be shaded or they will be of little value? "It is a local contingency to be overcome by local ingenuity," was the brief reply. In the end I freely admitted that he is quite right, and that there are plenty of spots where I could, and very probably shall, test this, as far as I know, original idea of Mr. Miller's. But it is nurserymen and original idea of Mr. Miller's. But it is nurserymen and others who grow Vines in pots largely every year that I am inclined to think will be the most benefited by the adoption of this practice, for they are better able to give up a house or houses, as the case may be, entirely to the growth of young Vines, and thus require but a small amount of local ingenuity to insure success. The saving of fuel and a crop of Grapes into the bargain alone ought to be an inducement to give the plan a fair trial. Where, however, the house room is limited the difficulty will be greater, and then comes the question, Where are the Vines to be grown? All certainly must depend on local circumstances. In some instances one or two Vines might be layered at intervals along the front of a house, and the ends of vineries might be especially utilised, as it is not at all necessary that the Vines be trained vertically, as they grow and fruit remarkably well trained perpendicularly. Peach houses, forcing pits, &c., too, all might easily be employed to propagate a few or many Vines.

Before reading Mr. Smith's remarks I had intended to offer a few observations on the subject of growing early Grapes, and will take the present opportunity of doing so. Where there is a demand for early Grapes, or at all events where it is incumbent on the gardener to keep up a continuous supply, the earliest are oftentimes cut from Vines in pots. These, unless unusually well grown, seldom produce a very valuable or presentable supply, and only serve to prevent the hard forcing of the established Vines. The object in view is a good one, and there is no reason why it cannot be attained, and also a supply of excellent Grapes obtained probably equal, as far as flavour is concerned, to any sent in to the table during the whole season. Much depends upon the preparation of the young Vines. The advance made by nurserymen of late years in this branch of their business is most marked, and it is surprising to see the quantity of splendid short-jointed canes they grow and

NO. 967.-VOL XXXVII., NEW SERIES

distribute. Formerly some at least used to pot them in the siftings of the rubbish heap; now they use good fresh loam and clean well-drained pots, and this much-improved treatment is very manifest in the healthy state of the roots and the quality of the canes.

Although the system of keeping the Vines in pots for two years previous to fruiting may appear more laborious and expensive, yet it is the practice I strongly recommend, believing it to be the best. After all it is not so much trouble as at first sight appears, and cut-backs have the advantage of being easily started early to form fruiting canes. In addition they, as a rule, are certainly stronger, shorter-jointed, and firmer than are those canes rapidly grown from eyes in one season. What I mean by firmness or solidity is the comparatively small amount of pith in the canes—a desideratum obvious to those possessing a practical knowledge of the Grape Vine.

Any time during January or February we commence operations by inserting a number of eyes into an ordinary shallow box, preferring this to small pots, and place them on a moderate hotbed in a vinery. When the Vines have rooted the best are potted off singly into 5-inch pots, returning them to a hotbed till established; after which they are grown-on either on the stages in front of the vinery or early Peach house. No further trouble is taken with them beyond supplying water regularly until after they are sufficiently hardened off to be turned out in the open. Any sunny spot does for them, and they require less water if plunged. They are sure to ripen, at least as much as is required, and can be wintered in a cold frame. Early in January they are introduced into heat and disbudded, leaving two buds at the base, one of which and also the old cane to be cut clean away when once the leader is fairly started. Disbudding is preferred to pruning, simply because Vines do not bleed if cut when in full growth. When the young Vines have broken they are shook out and potted in 12-inch pots. I have tried repotting the young Vines into 5 or 6-inch pots and shifting into the fruiting pots, but find that the roots do not spread so readily into the surrounding soil, and the ball is apt to get dry to the detriment of the roots, and the fresh soil is more liable to become sour before the roots have taken possession of it. The soil used consists of two parts of turfy loam to one of partly decomposed horse droppings—that scraped from the roads being preferred, and failing this we add road grit, as well as the usual sprinkling of bone dust. During the potting operation we throw in a few coarse pieces of broken bricks and mortar, their use being principally to prevent the roots from reaching the sides of the pots too soon, which otherwise they would do. The Vines are potted very firmly, and the pots used are clean and well drained. They are never placed in bottom heat, as that causes a too succulent growth; on the contrary, they are grown on the stages and trained up the roof between the permanent Vines, and also at intervals up the roof of the Peach house. They of course require a great amount of water of the same temperature of the house, in fact must never be allowed to flag for want of it, or the consequence will be the loss of some of the buds or leaves. We grow them to no particular length, but

NO. 1619.-VOL. LXIL, OLD SERIES.

head them back according to the strength of the cane, the longest being about 6 feet. The laterals are kept pinched back to one joint at each pinching. When the canes are commencing to harden and colour the temperature is either lowered or they are transferred to a cooler house for a time, and finally, when the canes are quite brown, to vacant spots on either south or west walls, to which they are trained, or rather fastened. When all danger of their pushing out the fruit buds is past the laterals are cut clean out and less water is given.

the laterals are cut clean out and less water is given.

The first season when I commenced to fruit Vines in pots they were plunged in a hotbed, but the roots soon spread into the dung from the bottom of the pots, and also by being covered up and encouraged from the top as well. This, as they succeeded beyond expectation, induced me to plant them out in a properly prepared compost, which practice I for the future intend to follow. The house in which we fruit them has a low span-roof with a pit in the south or front side, which partially encloses the hot-water pipes, and on the back roof a Stephanestis planted in a tub is trained. The pit is roughly drained, and filled with a compost of loam, garden soil, and good dung of any description in equal quantities, with an addition of a sprinkling of mortar rubbish and broken bricks. Slates are placed to keep the soil from the pipes, and they also serve to conduct the heat through the bed. The soil near the slates and also the ball require to be frequently watered, in fact almost daily, especially when the pipes have been much heated in the former case, and in the latter when root-action is brisk, and the whole bed about once a week. In the early stages clear tepid water is used, but when the Vines are well started the ball receives weak liquid manure at every watering, and later on the whole bed also. A good mulching of manure preserves and encourages the top roots and helps to keep in the moisture. Guano in experienced hands is the simplest, but liquid manure made from sheep droppings, pigeons' or chickens' manure, soot and lime, and mixed in sufficient strength to well colour, is equally as effective and safer to be used. We start the Vines in a temperature of 55° by night, increasing to 60° by day, and when root-action has fairly commenced this temperature is raised to 60° and 65°. To be brief, we follow the usual routine of tying back to cause them to break evenly, steaming, syringing, &c., often described in this Journal. Neither the temperature nor the humidity of the house was varied but little at blooming time; neither is it necessary where the root-action is so good. All, including the Muscats, set well; but as the Stephanotis had to be considered, the high temperature kept up when the Grapes were colouring to a certain extent affected the colour of the black, but not of the white varieties. We, however, lessened the supply of water, and to this and the high temperature must be attributed the very good flavour, as we had but little solar heat to sweeten them.

Treated as I have attempted to describe, the Vines were wonderfully fruitful, every joint producing several bunches, and these when reduced to a moderate number, according to the strength of the Vine, grow out surprisingly. Six bunches are enough for a strong Vine, and the smallest we fruited this year, a Black Hamburgh 4 feet long and the cane.only 14 inch in circumference, carried three bunches, which collectively weighed 9 fbs., and all the others carried heavy, though certainly not quite proportionately heavy, crops. I know of one solitary instance where equally as heavy crops have been taken from Vines in pots which were never even plunged, but not so early as we, although we did not start the Vines till January 9th and cut Grapes April 22nd. Our system may be laborious, but not so much so as that followed with the above-mentioned Vines in pots, as they required almost hourly attendance.

Black Hamburgh and Foster's Seedling ripen well together; and to follow these I recommend Madresfield Court and Muscat of Alexandria, as both succeed remarkably well under the foregoing treatment. They would carry a good crop the second year if properly ripened and rested; but we prefer cutting them out, not only on account of wanting the room for Melons, but because the young canes produce much the largest bunches. I have seen Vines planted in low span-roof houses succeed admirably for a few years, but both the canes and border under this mode must be renewed occasionally, say once in five or six years. Our young Vines will not be planted till January this year on account of their intended site being occupied by a crop of Tomatoes in pots, which are intended for the November and December supply. We, however, can prepare the pit, as the pets are on a moveable trellis which covers the pit. The soil will get thoroughly warmed, and if the young Seakale roots are fit to lift in time it will be planted with them for the

Christmas supply. The Vines will be introduced into heat in November providing they are ripe enough, which I question, in spite of being housed earlier than usual; but this is an exceptional season. I do not claim originality for my practice, but that it both deserves to be more generally followed, and is also in advance of the old practice of fruiting pot Vines I at least am fully persuaded; and this must be my apology, if one is needed, for offering these lengthy remarks on the subject.—W. IGGULDEN.

[No wood could be finer than that submitted; it is as hard as oak, and the pith is scarcely visible.—EDS.]

BUXTED PARK,

THE SEAT OF COLONEL FRANCIS VERNON HARCOURT.

HARD by the little station of Buxted, on the line of railway from Brighton to Tunbridge Wells, is Buxted Park, with the house, a massive pile of the palatial Italian style of architecture, standing upon an eminence surrounded by lofty old trees. There are four entrances to the park, and each has its average; that by which I went to the garden was a noble one of very lofty old Scotch Firs, not everywhere in uniform ranks, for the original lines are now broken and varied. Some are level with the road, others upon the sides and top of banks, irregular, and yet in perfect keeping with the rows of column-like stems that still exist. It is an indication of rare good taste and sound judgment that no attempt at replanting was visible in any of the vacant spaces of this old avenue. The common desire to do so is a mistaken one, as results generally show. Beyond the avenue the undulating surface of the park opens out picturesquely, and we obtain glimpses of the house and a church close by.

The shrubberies near the house are the first portion of the gardens that come into view, and are remarkable for the masses of Rhododendrons, most of them probably 12 feet in height, arranged in clumps and belts, with an ample expanse of grass lawns and various fine examples of some of our best varieties of Coniferse. An Abies Smithiana (morinda), the Weeping Spruce of the Himalayas, about 30 feet high, with the pendulous habit well developed, is the finest example of this graceful Conifer I have seen in Sussex. There is also a magnificent example of Pioca pectinata, with a huge bole some 6 feet in diameter; and also much other fine timber dispersed among the shrubs on the north and north-east side of the house. It is under the overhanging branches of a clump of these trees that one comes out from the shrubs to a highly finished arbour standing upon an elevated position, with a Rose garden in front of it and overlooking a fine stretch of wooded park and swelling uplands beyond. The Roses were all "faded and gone" at the time of my visit. Numerous Gladioli planted among the Roses were, however, in full beauty. This is a step in the right direction well worthy of imitation, imparting, as it does, the charm of variety and gaiety to what is usually a dull and unattractive scene at this season of the year.

From the Rose garden a terrace walk, broad and straight, runs for a considerable distance towards the house, with a chain of flower beds on one side and a belt of shrubs on the It forms an admirable boundary to this side of the dressed grounds, being sufficiently elevated to exclude cattle and to afford fine and varied views over the park, with vistas of hills and valleys through the tree openings, for the park stands in the very centre of some of the richest scenery of Sussex. The beds were well filled and gay with summer flowers, a pleasing variety being given by the introduction of an occasional bed of choice annuals among the Pelargoniums and fine-foliage plants, each bed containing some new introduction—some novelty but little known, of which I may select Phlox Drummondi grandiflora splendens as proving well worthy of its lengthy name. The flowers are each a perfect circular disk, with a broad marginal band of deep crimson, and a bold white centre with delicate pencillings of crimson. Near the last flower bed of the chain the walk branches right and left past an arbour, standing at the entrance of a grove of old timber, to a fernery around a pool of water amidst the We turn aside up an ornamental flight of stone steps to the upper and larger terrace flower garden adjoining the house. The turf-clad alopes on each side of the steps, that in ordinary hands would probably have presented no feature of interest, have been turned to account as a home for such plants as Desfontainia spinosa, Hydrangea paniculata grandiflora; Rhus Cotinus, a large specimen, with a cloud of its charming

feathery inflorescence in full perfection; and Bambusa falcata. The flower garden is of considerable extent, filling a large quadrangle and a wide approach from the steps and carriage front. The design is somewhat formal, yet in good keeping with the position and its surroundings—the house on one side, a conservatory on another, stone balustrading with numerous tazzas and vases enclosing the remainder; a central fountain, with a chaste architectural design, and some fine Irish and Golden Yews.

No contrast could be more striking, no change more agreeable, than that which greets us as we turn from the bright colours in the flower beds to the farmery with its hundreds of Ferns, all growing so freely in the subdued light of a natural arcade. No position could be more suitable for a farmery, and I wish to draw special attention to it because there are so many similar tree clumps or sheltering belts in other gardens that might be turned to account with very little labour. Onwards from the farmery a winding path takes us to the kitchen garden, some 3 acres in extent, enclosed by a high wall covered with fruit trees. Plans trees on the wall were laden with a heavy crop of fruit; so too were Morello Cherries, which, like the trees at Chiswick, have the growth left unpruned and growing cut from the wall, and are consequently far more productive of fruit than those which are pruned hard and kept close to the wall. It is unnecessary to dwell upon the vegetable exops. They were abundant and good, and the condition of every part of the garden was highly creditable to Mr. Prinsep, the able gardener, the excellent results of whose practice show clearly that he gives close attention to every

The glass houses are numerous, and are arranged in a compact block on one side of the kitchen garden. Vineries, with plenty of good Grapes; Peach houses equally satisfactory; span-roofed houses, with Melons, Cueumbers, pot Vines for early forcing, Plums in pots laden with fruit; a house just filled with a collection of Zonal Geraniums for winter flowering, which will enjoy a temperature of 50° throughout winter, every plant so well grown as to be suitable either for table decention or to afford a supply of cut flowers; an exotic fernery; a pair of span-roofed stoves with central stages devoted to miscellaneous plants, and side stages filled principally with Orchids, all in flourishing condition. Numerous in posts in full bearing; another Kidney Beans, to follow the last crop out of doors; another a sturdy batch of Poinsettias, enjoying a gentle bottom heat, but having the lights drawn off in the day, with the plants fully exposed; another with crimson and yellow-berried Rivinas. But it is unnecessary to enumerate further. In justice to Mr. Priesep I must add that from the conservatory, with its choice Palms and fine-foliaged plants, downwards to the frames, in which cuttings of bedding plants were being inserted, everything was well done.

EDWARD LUCKHURST.

GRAPES WITHOUT FIRE HEAT.

I, LIKE others, felt some surprise when I read about Mr-Muir's Grapes being ripe "without fire heat" some time since, but none when I learnt that he had a fiue in the house. Everyone who knows anything about the growing of Grapes is aware of the great advantage of fire heat to start the Vines into growth; therefore I do not consider Mr. Muir is correct when he said that his Grapes were grown without heat. Mr. Hilton is in the same category. My Grapes grown in my plant house, which had a fire all the winter and is still full of plants, were ripe some time ago, and were fine in colour, bloom, and size, but I should not think for one moment of saying they were grown without fire heat. My second house has no flue nor wines and therefore is executively a house without fire heat

pipes, and therefore is essentially a house without fire heat.

This year the dull weather has been much against my being successful, still I think I shall shortly ripen the following varieties in this order:—"The Artist," a seedling of my own; the berries are now black, and I have cut a bunch of good flavour. This is the earliest Grape I have, nearly a fortnight before the Black Hamburgh in the same house. The Champion Muscat will, I think, be next, then the Black Hamburgh, then Venn's Muscat This is the most marvellous bearer I ever had. I have now a second crop coming on in my house where heat was applied, and think they will ripen. Next will be Madresfield Court and the Black Alicante. These are all in a cold house without any fire heat. In my ground vinery none will ripen this year but a bunch or two of Madresfield Court and the Champion

Muscat. Whilst I am writing on the subject I may state as my own opinion that I consider the Muscat of Alexandria, the Champion Muscat, the Duke of Buccleuch, Venn's Muscat, and the Black Hamburgh the best of all Grapes. The Madrasfield Court is a fine Grape, but cracks with me do what I will. By the way I like the Trentham Black: it is rich and goed; and for flavour, colour, and bloom "The Artist" is not to be despised.—HARRISON WEER.

SINCE writing my letter on the above subject (page 249) I have seen some Black Hamburgh Grapes that had been ripened without any fire heat whatever, for there is nothing provided to heat the house. The house I have referred to belongs to a farmer, and I am told the Vines bear annually a good crop of Grapes. Perhaps this may be of some interest to "A. C. M." and others who may have vineries without any provision for heating them.—G. Hilton, Great Tetham, Econ.

HAMPTON COURT.

THE flower beds here, although not so brilliant as they were last season, are again remarkably well planted, and but for the long-continued unfavourable weather would have been very grand indeed. No attempt is made at subtropical bedding, simply because they have neither specimens suitable for the work, or in fact sufficient house accommodation to near and keep them in. In none of the public parks, however, are either the ordinary summer bedding or carpet hedding better flone, the designs for the latter being very original and good. Mr. Graham, the able Superintendent, now annually issues a fresh edition of an extremely handy little "Guide" to the gardens, &c., which not only contains the key to the arrangements of all the beds, and for this reason alone very requisite to the innumerable visitors, but also many practical hints upon the propagation of a great variety of bedding plants, numbers of excellent arrangements, diagrams for carpet beds, &c., which would be very useful to many in their future work of arranging, &c.

There are nearly one hundred large beds in all, besides a very long border, and some idea may be formed of the great variety they present when it is stated that there are but one or two pairs among them. It will be noticed in the following description of a few of the most attractive beds that the edgings, and more especially the "inner edgings," are not single lines but good broad bands, and very effective they were too. The numbers given correspond with the beds, and the description is taken from the "Guide." The first to be noticed is No. 6. Centre, Pelargonium Crystal Palace Gem and Viela Blue Perfection, edged with two rows of Ireans Linden; outside edging, Symphoricarpus montana variegats. No. 10.—Centre, Pelargonium Lucius, edged with two rows of Abutilon vexilrelargonium Licius, suget with two rows or Abuthon vexil-larium variegatum; outside edging, Alyssum saxatile variegatus. No. 15.—Centre, Pelargonium Bijou and Viola Favourite; edging, Coleus Verschaffeltii. No. 19.—Centre, Pelargonium Mrs. Pollock and Viola Tory; edging, very broad, Coleus Verschaffeltii. No. 29.—This was very striking. Centre, Pelargonium Crystal Palace Gem and Viola Tory, edged with Iresine Iindeni; outer edging, Euonymus madicans variegata. No. 52.—Centre, Pelargonium Bijou and Dactylis glomerata, edged with Iresine Herbstii; outer edging, Euonymus radicans. As will be seen by the foregoing, many of the centres are mixed. They are very effective; and, as Mr. Gmham pointed out, if the summer prove hot and dry the Violas, which are principally used with Pelargoniums, perhaps fail, but on the other hand the latter flower freely. This season there was but little bloom on the Pelargonium but the Violas are very showy, and contrast admirably with the silver or golden variegated foliage of the former. The arrangement, therefore, is very effective and safe. Among the new varieties of Pelargoniums employed the best appeared to be Dr. Denny's Commander-in-Chief, the truss of which was very good, the flower of great substance and of a rich scarlet colour, and is apparently a good variety for either wet or dry ROBRODS.

The carpet beds were very good indeed, but without diagrams it is useless to attempt to describe them, and we will confine our remarks to a list of a few of the plants used. The favourite green foliage plant is Herniaria glabra, being less trouble than the Mentha and quite as effective. Several varieties of Alternanthera were used. Amona and magnifica were very bright, but paronychioides was the only variety that filled up well. Several Sempervivums were used, arachnoideum and

soboliferum being very noticeable. Kleinia repens proved a very useful succulent for lines, &c., and Leucophyton Brownii was largely and effectively used. Echeveria Peacockii is considered by Mr. Graham to be the best of that useful class of plants. It may be described as being a great improvement on Echeveria secunda glauca, and can be used in a similar manner to that popular variety. Antennaria tomentosa and Veronica incana are good silvery foliage plants, and are quite hardy and very effective. Mr. Graham has a number of canvas covers to protect the carpet beds, by this means prolonging their beauty long after the usual time.

DUPLICATE ROSES.

THE readiness with which the worthy Secretary of the National Rose Society is willing to undertake the task of obtaining the various opinions of exhibitors respecting the vexed question of duplicate Roses shows plainly there is a necessity of something being done in the matter. I think the difficulties he fears would not amount to much if he conducted his inquiries somewhat after the manner of Mr. Hinton's Rose election, and so let the majority carry the day. Then if the National Society acted on the decision of the Committee minor societies would very soon follow in the track, and the thing would be done.

Though such an authority as Mr. Wm. Paul may be able to identify equally good blooms of the three most nearly alikeviz., Maurice Bernardin, Ferdinand de Lesseps, and Exposition de Brie, and much as I respect his judgment in everything connected with the Rose, still there are others who act as judges who will not admit that there is any difference between them, and consequently fail to detect any. Mr. C. P. Peach says he has grown all the Roses mentioned as duplicates and cannot agree to their identity, with but one exception—Ferdinand de Lesseps and Camille Bernardin. Surely this makes confusion more confounding, as I never heard that these resembled each other in the least. He says, too, that Exposition de Brie is perfectly distinct in habit from any other Rose. Now the habit of a Rose cannot be judged of by a single bloom, consequently that is nothing to enable anyone to distinguish it by on an exhibition table.—OXONIAN.

HARDY FRUIT AND FRUIT JUDGING AT NEWCASTLE.

In reference to the remarks made by the Rev. C. P. Peach in the Journal of Horticulture, page 248, respecting hardy fruit and fruit judging at the late Show, I assure him that the collection which obtained the first prize was all grown in these gardens without any protection, with the exception of the single dish of Goliath Plums. I certainly think the Committee have taken all the necessary precautions in order to keep the collection strictly hardy, seeing that they neither allow Peaches, Nectarines, nor Apricots to compete as hardy fruit. With regard to Mr. Peach's remarks respecting the collection of eight dishes of forced fruit, I thoroughly endorse his opinion. I felt great surprise at the decision, and several eminent fruit-growers present were unanimous in their opinion that it was a flagrant mistake, and advised me to make a protest to the Committee. Upon making a protest I was courteously received by the Committee, whom I requested to examine the fruit, which they did before a group of disinterested observers, and when they lifted the suspected Melon from the dish they found (small as it was) that it was so far decomposed as to be completely flattened by its own weight. I then requested the Committee to present my verbal protest to the Judges, which they did most willingly. The Judges' reply was that they were enabled to justify their award without considering the state of the Melon. This I thought was most unjust, as they were bound to consider the condition of all eight dishes, and if, from whatever cause, one dish is found not admissible it disqualifies the rest.

I had no intention of bringing the matter before the public until urged to do so by many of my friends, who thought it a valuable subject for the perusal of exhibitors and those who have the compiling of prize schedules for the ensuing year. If all prize lists for fruit were prefaced with a request that "all fruit must be ripe and fit for table" it would afford protection for judges and competitors alike.

There is also another irregular and very unsatisfactory practice noticeable at Newcastle as well as at almost every other fruit show—that is, quantity being preferred to quality in col-

lections. I think the number of fruits required to constitute a dish should be stated, which can easily be done with all kinds with the exception of bush fruits, which may safely be left to the exhibitor's discretion.—R. WESTOOTT, The Gardens, Raby Castle, Darlington.

PALMS.

I know of nothing so suitable for general decorative purposes as the beautiful and much-enduring Palms, which are coming into more notice every year. There is a peculiar interest about them, arising to a great extent from their frequent men-tion in Holy Writ, and also from the associations connected with warm eastern and southern climes, which the very name of Palm seems to call up immediately before our minds. In almost all, or perhaps I might say in all, hot climates Palms some sort form a conspicuous feature of the prevailing vegetation. In the midst of our own dark cheerless winter, when we are enduring bitter east winds and the early Snowdrops are shivering in the blast, we hear from our consumptive friends in their voluntary exile in Algeria or Mentone of the warm sun-shine lighting up Palms and Citrons and Olives, and the ground being already bright with Hepaticas, Cyclamens, and wild Hyacinths, and we seem to be in a warm climate ourselves for a moment when we read of the many charms of the sunny south. Not that I for one would wish to change our English climate, capricious though it may be, for any other which I have met with or read of in other lands. We cannot have the warmth of their delicious winters, but neither have we the intolerable heat of their parching summers. If your business requires you to stay in one place all the year round, depend upon it there are few countries which can equal in climatic advantages our own seagirt isle.

I fancy we are much behind our continental neighbours in using Palms for decoration. I remember many years ago seeing in the market at Brussels very good Palms in 5-inch pots at one franc each. I think they were either Corypha australis or Latania borbonica. They would have speedily grown into handsome plants, for, as every grower of Palms knows, when once you have got them out of the baby age they make much more rapid progress than before. I noticed in Covent Garden this spring some beautiful little plants of Cocos Weddellians in thumb pots at a very low price. I should have carried them off with me, but it is hard to take possession of a pot plant in the middle of London. Especially is this the case if you are on a foreign tour, and things look suspicious, and the porters in their blue blouses are jabbering their own patois all around you. I could tell some stories of odd dilemmas in that way,

but I must go on with the Palms.

It is wonderful how long some of those Palms which do not require much heat will stand the dry air and the occasional draughts of the drawing-room. I had a fine specimen of Phoenix dactylifers in the drawing-room the whole of last winter and far on into the late spring, when it was sent out into the vinery to recruit. This plant, with many others, I raised from seed, which makes all the difference in point of interest. The receipt is to buy a pound of dates for 8d., to eat the fruit, or, if you do not like them yourself, to give them to your children, but to keep all the stones, which sow in heat, and you will be rewarded in a comparatively short time with fine young plants, capable of bearing a good deal of cold and draught and making a beautiful ornament for the drawing-room or the study. The first two or three leaves are simply broad grass-like fronds, but even these are graceful; the divided fronds, which come afterwards, are really most charming in their effect either separate or grouped with other Palms. This Phœnix dactylifera is the Palm of Holy Scripture, the one which once grew so abundantly round Jericho, the city of Palm trees; and it was, of course, tall fronds from this Palm which the people strewed in the path of our Saviour when He rode triumphantly into Jerusalem. On this account it has a special interest for most of us, who like to look at our plants not merely for their own beauty or for their own structural peculiarities, but also for the thoughts which may be attached to them in the mind of the grower. Phœnicia was so called from the quantity of this Palm which grew there formerly.

Seaforthia elegans is one of the most beautiful Palms where there is room for it. It requires space and generous treatment, and then few things can come up to the graceful beauty of a large plant of it with the older fronds bending down in a fine curve and the new fronds pushing straight up in the centre. This is the Palm now generally used on Palm Sunday, and tied up in an ernamental fashion by the natives of Madeira and along the ceast of the Mediterranean for that purpose. I should like to know how the fronds are made so beautifully white in their dried condition. They are frequently brought home and made use of as a room ornament hung upon the wall. I have tried the Seaforthia out of doors in summer, but it spoils the beauty of the plant, which is nothing once the green symmetry of the whole is injured.

I once had a case of Palms brought home for me from Australia. They travelled perfectly well in a glass case protected with boards. In it were two prickly Palms covered thickly with spines. They were labelled Calamus australis, but as there is no Palm known of that name I believe it was a mistake for Calamus asperrimus. They have since made fine specimens. Two plants of Corypha australis grew rapidly after their arrival, and are now grand specimens, no longer capable of being carried into church for decorative purposes as of old. Latania borbonica is a more beautiful Palm of much the same external character. I see that by some the latter is called Livistona sinensis, and the former Livistona australis. For table decoration it is necessary to have kinds which

For table decoration it is necessary to have kinds which grow in a smaller way, and of these, so far as my experience goes, Cocos Weddelliana is facile princeps. It is a beautiful light feathery-looking Palm with graceful arching fronds, which are minutely divided. It is one of the slow-growing Palms, and therefore it is necessary to be patient with it. But even in its babyhood it is beautiful. It makes an excellent plant for the dinner table whether small or large. In the small state five or six of them in small silver stands look exceedingly well; in a larger state of course they must take a more central position. Their great recommendation is, that in common with the whole tribe they will bear so much knocking about. Cocos Weddelliana is, however, a Palm which likes a warm house.

Areca monostachya, or the Cabbage Palm, though not so beautiful as many, is a singular plant; the knotted stem is peculiar and gives it the character of a small tree. Areca sapida is somewhat tender; its spiral mode of growth is pretty, and well grown it makes a fine specimen. I have found it too delicate to associate with Corphya australis, or even with the Calamus.

It is by no means necessary to have even a cool greenhouse to grow the hardier Palms. With a little care and attention they will be found to accommodate themselves to the sittingroom. Those who have rooms large enough cannot introduce any ornament more graceful than a fine specimen of Lataue borbonica or Corypha australis; and those who have less space in their rooms may rejoice in the more upright growth of the beautiful genus Phœnix, which includes several good species. The genus Chamserops is another of the more hardy race. They will stand out of doors well in the west country. Many readers of this Journal are familiar with the magnificent Palm in the grounds of the Hon and Rev. T. Boscawen at Lamorran, and at another place in Cornwall an avenue of Palms has been lately planted. A specimen of Chamserops humilis which I put out last year almost survived the very trying winter. Another specimen put out this year shall have its chance with the ensuing winter. It is wonderful how a Palm starts into growth as soon as it is taken out of its pot and put out with a depth of cool damp soil beneath it. I have no doubt with a little wrapping-up Palms could be easily kept alive through our Gloucestershire winters, but I always think it is a pity to spoil the look of a winter garden for the sake of preserving a specimen which would do much better indoors. A mat against the wall is not so conspicuous, nor does it spoil the general appearance of other things, but even that is bad enough. On the whole it is better to be satisfied with things which can really bear our climate, though attempts at acclimatisation are always interesting.—A GLOUCESTER-SHIRE PARSON.

WHICH ARE THE BEST VEGETABLES TO GROW?

It is not at all times so easy to answer this query. What one gardener considers the best another will not grow. Two vegetables I have grown this year I unhesitatingly give the palm to—viz., Early Vienna Savoy and Sutton's Improved Dark Red Beet. Earliest Vienna Savoy I have grown this year for the first time. It was sown on April 2nd, together with Tom Thumb, Dwarf Green Curled, Early Ulm. Earliest Vienna had fine large solid heads fit to cut on August 25th; the other varieties are just now (October 1st) coming in, but none of

them will have such fine heads as the Vienna. Sutton's Dark Red Beet I have grown three years, and have tried it with the best of other varieties, and find none to equal it for ornament or use; for the future I shall grow no other, excepting the Egyptian for summer use, which is invaluable.—J. LANSDEN, The Gardons, Barkby Hall, Leicester.

ABOUT LIVERPOOL.—No. 4. CALDERSTONE.

THIS, the seat of Charles MacIver, Esq., is situated four miles from Liverpool, and about one mile and a half from the river Mersey. Considering its nearness to such a large town the estate and the gardens are rather extensive. The drive leads through the park from the Allerton side for a good distance before reaching the mansion. The park, being moderate in size, has an even surface and is well wooded. Trees have grown remarkably well at Calderstone in days gone by, and they thrive even now much better than many would anticipate. Following the drive we pass under the shade of some fine old forest trees intermixed with large specimens of Rhododendrons, Yews, Cedars, Hollies, &c. The last named we refer to specially on account of their free growth. There are some magnifi-cent specimens of the Silver-leaved variety, the common Holly, and the fine dark-leaved variety Hodginsii, which grows luxuriantly. The soil at Calderstone appears to be well adapted to the growth of Hollies. The principal features of interest at Calderstone are the old Oak, the glass houses, and the Chrysan-themums. To turn to the first of these, the old Oak stands on a good and well-kept lawn some distance from the house. The branches, which project a great distance from the main stem, are supported by iron stays. Should this gigantic old tree by accident fall to the ground the lawn at Calderstone would be deprived of its principal object of attraction. The shrubs, both flowering and ornamental, are more luxuriant and healthy than in the majority of places within the same radius of Liver-pool. They are judiciously arranged in clumps on the lawn, and present nowhere that crowded appearance perceptible in many places, and the walks have where necessary gentle and easy

Amongst the glass houses we will first notice the Pine stove. It is a fine span-roofed house of great length and width, with a walk down the centre and a narrow one close to the front on each side, for the purpose of conveniently attending to the Pines when they require watering. Good shelves are also arranged down the centre close to the glass for French Beans arranged down the centre close to the glass for French Beans and Strawberries. The Pines are very good, and the appearance of the fruit speaks very highly for Mr. Dunnington's system of cultivation. The plants are both planted out and grown in pots; but the latter mode is preferred. The pips of the fruit in the majority of cases swell to a very large size in this house, much larger than we have generally seen them; and the latter mode are desired and steak. The part house is given by plants are dwarf and stocky. The next house is similar to the last mentioned, and runs parallel with it, but is not quite so long; it is devoted to stove plants, the contents being clean and well grown. We noted several well-developed plants of different varieties of Crotons and Dracenas. The Gardenias were large and pyramidal-trained, and must from their size and appearance produce every year quantities of their sweet welcome flowers. Bougainvillea glabra is planted out at one end of the house, and runs to the other like a long Vine; it is pruned on the spur system and blooms profusely. Allamanda Schotti is also grown on the same principle, but on the opposite side. Specimens of Dendrobium nobile are numerous and extra fine, having pseudobulbs nearly 4 feet in length. Amongst the Orchids in this house we noticed Dendrobium Wardianum, D. thyrsiflorum, D. Bensoniæ, D. primulinum, D. formosum giganteum, D. chrysotoxum, a fine species generally known in gardens as moniliforme, and the lovely D. Falconerii, Cypripedium Parishii with thirteen flowers open, C. villosum, C. caudatum, C. niveum, C. hirsutissimum and others; Odonto-glossum Alexandræ, O. Pescatorei, and O. triumphans. These were grown in the stove and thrive wonderfully well. We also noticed several Cattleyas, Oncidiums, and Phalænopsis. Two span-roofed houses are devoted to Melons, and their cultivation is well understood at Calderstone. The next house is devoted to Heaths, amongst which we noticed good plants of Erica Marnockiana, E. Turnbullii, E. Victoria Regina, E. tricolor Barnesii, E. ampullacea, E. perspicua nana, E. Cavendishiana, and E. depressa multiflora. Epacrises, both large and small, were in very good condition. There is also a good-sized house devoted to Azaleas and Camellias. Before leaving the plant houses it would be well to remark that Kalosanthes are well grown. We noticed in a plant pit some well-bloomed specimens, also some grand Epiphyllums with immense heads and in good condition. The conservatory is not large, but was at the time of our visit gay with seasonable flowering plants, and very conspicuous was Campanula pyramidalis, and a large Camellia in the centre. The roof is draped with a quantity of climbers, and the one most striking of all was Abutilon megapotamicum variegatam, which was flowering most profusely and hanging in festoons from the roof.

The houses were rather scattered, and we had to pass through the fruit garden before we reach the fruit houses. There are four houses devoted to the cultivation of Vines, one for early Grapes, one for Muscats, and the other two are late houses. The early one is planted with Black Hamburghs and Muscats, which were carrying a fine crop such as Grape-growers might be proud of showing. The two varieties can be grown together well with judicious management. The Grapes in all the houses were very good, and the Vines in fine condition. We noticed a good bunch or two on a young Vine of the variety Mrs. Pearson, and Mr. Dunnington speaks very favourably of it. Two houses are devoted to Peaches and Nectarines; all the fruit had been gathered previous to our visit. The trees mostly are of a good age, but never fail to produce heavy crops of fine fruit. These trees are well managed, thinly trained, and in every respect well attended to. The early house contains a good tree of Early Beatrice, which ripens fully a fortnight earlier than any other variety, and Mr. Dunnington speaks of discarding it because its fruit are undersized. The fruit garden above mentioned is a large-sized piece of ground and enclosed with high walls, which are furnished with well-trained trees, the south wall being covered with Peaches and Apricots. The crop of the former round Liverpool is very uncertain, and none of the fruit will ripen this year. Others are covered with Cherries, Plums and Pears, which are only half a crop and very small. Down the centre walk of the garden and running north and south is a large archway of ironwork, and entirely covered with Pears on the cordon system. The arrangement is nest and striking on the whole, but as far as the crop is concerned it is next to a failure. Quantities of fine well-trained pyramidal Pears and Apples stand by the side of the walks, and large squares are entirely devoted to Strawberries, Raspberries, Currents, and Gooseberzies. On one side we observed a hedge of Gooseberries which were covered with fruit. At the end of one of the houses in this garden we noticed a collection of Anemones and Ranunculus although out of bloom. Mr. Dunnington informed us they had been magnificent, and are well worth see-ing when in flower. They deserve to be much more extensively cultivated, and would, we are sure, afford pleasure and interest to the general lovers of beautiful flowers.

We will lastly notice that beautiful autumn and winter-owering plant—viz., the Chrysanthemum, which has of late flowering plantexcited much attention not only round the neighbourhood of Liverpool but in other localities. We may at the outset say that Mr. Dunnington is the champion grower of the Chrysanthemum round the vicinity of Liverpeol. No doubt the readers of the Journal, at least that portion of them that are growers of this fine flower, will be well able to form a good idea of the blooms Mr. Dunnington's plants produce when he holds such an elevated position in such a Chrysanthemum-growing district. We searcely need go back to last year, but we believe his blooms were as near perfection as it was possible to grow them. So thoroughly acquainted is Mr. Dunnington with these plants that they are all known to him by the foliage, and he further knows to a day how long the blooms of the different varieties take to unfold and properly develope. The plants are never plunged, but are standing on boards in a sheltered corner where It is impossible for wind to affect them. Late propagating is also practised. We may add trained plants are not grown for exhibition, what few are grown are for home decoration.

The kitchen garden is situated a short distance away, and was clean and well cropped; in fact every department is well kept and cared for, which shows abundant proof of Mr. Dunnington's abilities as a good and clever gardener.-J. W.

NOTES ON POTATOES.

My estimation of some of the varieties may not be in keeping with other seasons, other growers, or other situations. It is given just as the quality and character of the Potatoes seem to suggest at the present time. In such extraordinary seasons as the two last have been, it becomes more and more necessary

to depend upon the earlier varieties. Early planting, early lifting and storing, is really the only way to save them. The six varieties that have produced the best results generally I

have marked thus (*):—
Paterson's Victoria and Fluke Kidney.—These are usually two of the most valuable and best; both preduced only a very light crop, and nearly all have gone had either before or after

they were taken up.

Schoolmaster.—Sample very small and quality not at all

satisfactory. Evidently does not like our cold soil.

*Porter's Eucolsion.—One of the best round Potatoes, not so white as one could wish. A very fine crop and almost free from disease.

Red Emperor.-White when cooked, and good flavoured, nearly round in shape, shallow eyes; good exhibition variety. Many diseased.

Queen.-We can see no queenly or special merit in this, and it is late in ripening.

Red-skinned Flourball.—Very rough sample and not good

in quality.

Roun's Bountiful.—Produces many small ence, but telerably dry and good and not much diseased.

Sultan .- The merit in this is, that it will keep very late. Will certainly be discarded by us.

*Climas.—Though not the heaviest crop the results are of the best—almost free from disease, very few small tubers,

moderately dry and very good.

Rector of Woodstock.—This has produced too many small tubers, and is not a good colour. A few diseased.

Myatt's Prolific.—Well-known variety, light drop but good, and very few diseased.

*Early Alpha.—The best early in the list, dwarf habit, handsome shape, white, good flavour, and very early. Very few diseased.

Extra Early Vermont.—Similar to Early Rose, makes less haulm, earlier, and this season much more diseased.

*Early Ros.—Well known as an extraordmary heavy cropper, not so dry as usual; in other respects a very fine

sample, and very few have took the disease.

King of the Earlies.—Quite necless, at any rate to use. Might be used perhaps for frying, there being no danger of its

breaking.

Milky White.—One of the best in quality, but a light crop

and much diseased. *Magnum Bonum .---A very fine and handsome Potato; moderately dry, and only a few diseased.

Brownell's Beauty.—Cooks well, but is rough-looking with deep eyes, and many diseased.

Breese's Peerless .- At present this does not cook well, close and watery. Is one of the handsomest, with very shallow eyes, but few diseased, and a fine sample; probably would be good on a dry soil.

*Late Rose.-A very fine crop, cooks well, but will no doubt

improve by keeping.

By way of testing the productiveness of some of the popular varieties of Potatoes I this season planted the undermentioned varieties on the same day. No extraordinary means were adopted to obtain large crops, the object merely being to ascertain the relative productiveness of the varieties under ordinary cultivation. Four pounds of each wariety were planted, with the following results. Mysti's Prolific yielded 68 lbs., Early Alpha 86, Extra Early Vermont 98, Early Rose 92, King of the Earlies 54, Milky White 67, Magnum Bonum 60, Brownell's Beauty 52, Bresse's Pearless 52, Schoolmaster 73, Porter's Excelsior 92, Fenn's Bountiful 70, Climax 60, Rector of Woodstock 50, Redkinned Flourball 64, Sultan 33, Queen 40, Red Emperor 48, Paterson's Victoria 21, Late Rose 91, and Fluke Kidney 24.— C. MAXTED, Kearnesy Abbey, Dover.

NOTES AND GLEANINGS.

"THE sight of a sickly bed of TRANSPLANTED HEATHER," writes Mr. Luckhurst, "reminds us of a fact not generally known and which might be turned to account in the formation of beds of this ornamental plant. When soil is broken up near beds of Heather a spontaneous growth of its seedlings soon appears, which shows that its seed generally ripens. Sprays of it cut just as the flowers fade and stuck about the surface of a bed of peat would no doubt afford plenty of seed-lings. In the red sandstone and ironstone districts a preparation of peat is unnecessary. We have now an abundant growth of seedlings upon the sides of a cutting throughout a bed of gravel where the seed has evidently fallen among the gravel from some old plants growing along the top of the alopes."

A TRIO of DRACENAS FOR TABLE DECORATION of great merit, but which are not widely known, are Ernesti, Jucunda, and Sidneyi. They were raised by Mr. F. Bause at Mr. Wills's Melbourne Nursery, Anerley. D. Ernesti has leaves about 1½ inch in width and 9 inches in length, which arch gracefully, forming the segment of a circle: colour dark bronze margined with bright crimson. Very bright and elegant. D. Jucunda is of taller growth, the leaves being lanceolate, about 1 inch in width and 15 inches in length; dark margined with deep crimson. Hardy and good. D. Sidneyi is intermediate in habit between the two, and is very bright in colour, but rather more tender, yet very cheerful. These three slendergrowing varieties are specially adapted for the purpose named, and will prove valuable for various decorative purposes.

—— "J.R.S.C." WRITES:—"One of the results of the singular summer and autumn of this year is the appearance of an exceptional number of late WILD FLOWERS. Many continue in bloom up to the present time that would in ordinary years have died down. In North Kent some of the fields and hedges are still gay with Anagallis arvensis, Viola tricolor, Euphrasia officinalis, Genista pilosa, and Cichorium Intybus, amongst others of less note."

A CORRESPONDENT communicates the following on the PAMPAS GRASS AND ARUNDO CONSPICUA:—"Fast as the Pampas Grass is now growing, it is too late in the season to admit of the possibility of a full development of these silvery plumes which usually enliven our gardens at this season of the year. October has arrived, and its lower temperature inducing a cessation of growth, and we must, therefore, for once forego the enjoyment of our favourite in its usual autumnal guise. Yet while we abstain from useless regrets, it should not be forgotten that although in Arundo compicus we have not a substitute for Gynerium, it is certainly an ornamental Reed Grass of great beauty, which this year atomes in some measure for the failure of its gigantic congener. Its slender elegant spikes usually appear early in August. This year they were a month later, and are still unfaded."

— A BEAUTIFUL Fern, placed in commerce we believe by Messrs. Ireland & Thompson, Edinburgh, is ADIANTUM FLEMINGII. It has considerable resemblance to A. concinnum, but the plant is of more stately growth with longer and darker fronds. It makes a handsome medium-sized specimen, especially in the autumn when the fronds assume their dark hue; in the spring and early summer months its distinctive character is less apparent. It is of free growth, massive, and elegant.

WE have received from Mr. H. G. Smythe of Endell Street, Long Acre, a sample of a "new POT SCRUBBER, or pot-washing brush." It is of very simple construction, being entirely composed of coir (cocca-nut) fibre; it is light but firm, of a convenient size, and excellently adapted for the purpose of cleaning pots. The price, too, is very moderate—6d. each, or 5s. per dozen.

—— In the Temperate house at Kew the very beautiful and distinct VACCINIUM RUGOSUM is now flowering. The plant is shrubby in habit, and the leaves are narrow lance-shaped with serrate margins. The flowers are borne in small pendulous racemes, which spring from the axils of the leaves. The calyx is persistent, of a reddish tinge, and the corolla is urceolate (urn-shaped), faintly suffused with red, and of a semi-transparent texture, with five prominent longitudinal ridges; the limb is small with five reflexed pale yellow teeth. What renders the appearance of the flowers so distinct are the irregular wavy bands of dark red which surround the corolla. This really pretty plant was presented to the authorities at Kew a few years back by Messrs. Veitch of Chalsea. Another pretty species of the same genus is near the above—viz., V. erythrinum, a native of Java. It bears long racemes of dark red urn-shaped flowers."

THE luxuriance and abundance of FUCHSIAS in the Isle of Wight is very striking to a stranger, and this is especially the case in the towns of Ryde and Ventnor, where nearly every garden has several handsome specimens, which during the summer months are loaded with their bright little flowers. Varieties of F. magellanica and F. Riccartoni are chiefly grown, and they form in some instances enormous specimens 6 feet high and the same in diameter.

- In the gardens on the southern coast of the Isle of

Wight HYDRANGMAS have this season been extremely fine. Some of the immense plants near Ventuor, which are quite 10 feet in diameter, have been masses of bloom for a considerable time. The predominating colour is a most levely pale blue, a few shades of pink being visible in some of the heads. The soil in the neighbourhood is strongly impregnated with ron, and this may possibly have some influence on the colour.

— AT Possingworth, near Uckfield, Phoemium Tenax, the New Zealand Flax, has for some years been established in a sheltered but somewhat damp position in the open garden. A huge plant of it some 6 feet in height is now in full bloom, and presents a very striking and ornamental appearance. The colour of the curious flowers is a rich brown-red, not lemon colour as is erroneously stated in a work on subtropical gardening, and the clustering spikes afford a pleasing contrast to the familiar broad green curved foliage. Mr. Reid informs us that this plant ripened its seed three years ago; which important fact shows that it may now be regarded as one of our best hardy plants in the southern counties.

— WE have received the second part of "EUROPEAN FERNS," now being published by Messrs. Cassell, Petter, and Galpin. It contains a coloured plate showing the species of Woodsia, with descriptive letterpress, and a continuation of the introduction.

CHOICE GARDEN ORCHIDS.—No. 8. CATTLEYA.

(Continued from page 174.)

Cattleya guttata, Lindl. (Bot. Mag., t. 3693). Syn., Cattleya sphenophora, Moore; C. elattor, Hort.—A tall free-growing species, attaining a height of 1 to 2 feet, forming large masses in its native wide, from whence we have received it in clumps of 1 to 3 feet in diameter. Pseudobulbs stem-like, terete, and much furrowed. Leaves mostly in pairs, oblong obtuse, concave, the base semewhat narrowed, coriaceous, and deep green. Scape erect, longer than the leaves, bearing five to ten large fleshy flowers. Sepals and petals nearly equal, linear oblong, acuminate. Petals slightly wavy; colour green, tinged with yellow, and dotted with red. Lip three-lobed; lateral lobes owate, hooded; middle lobe somewhat cuneate, with tubercles on the disc, white and rosy purple. It blooms during the autumn months. Native of Brazil. 1827.

C. gettata, Lindl.; var. Loopoldii, Rchb. fil. (Pescatorea, t. 43). (Illust. Hort., t. 1471-2). Syn., Cattleya Leopoldii, Hort. Versch.—This variety resembles the species in habit; the pseudobulbe are, however, somewhat stouter. Scape erect, many-flowered, as many as thirty blooms being sometimes developed, although ten to twenty are more frequently seen. Sepals and pstals chocolate, profusely spotted with deep red; lip of a uniform reddish purple throughout. It blooms during

the summer months. Native of St. Catherine's, Brazil.

C. granelosa, Lindl. (Bot. Mag., t. 5048).—It has become somewhat fashionable of late years to decry this species and its varieties; they, however, amply repay any attention bestowed upon them. Sir Wm. Hooker in 1858, when giving the figure quoted above, says, "Even a quarto plate scarcely suffices to do justice to a well-grown specimen of this noble Cattleya." True, we have been made acquainted with many new and gorgeous species and varieties during the twenty years which have elapsed since that was written, but C. granuloss should not be turned out from any collections of these plants. Pseudobulbs stem-like, furrowed, 12 to 18 inches long, two-leaved. Leaves oblong-lanceolate, obtuse, coriaceous, and dark green. Scape terminal, erect, six to eight-flowered. Sepals oblong-lanceolate, slightly falcate, acute. Petals obvate, much broader than the sepals, waved at the margin, and coarsely toothed; the whole of a uniform olive green, irregularly spotted with crimson. Lip three-lobed; lateral lobes cucullate, enclosing the column, white without, pale yellow on the inside; middle lobe narrow at the base, where it is deep orange, ultimately expanding into a broad, sub-reniform limb, which is emarginate in front, finely denticulate at the edge, and furnished with a profusion of small fleshy tubercles (granulated); ground colour white, the granulations being deep rose. It blooms during August and September. Guatemals. 1840.

C. amethystoglossa (fig. 31), Rehb. fil. (Bot. Mag., t. 5688). (Warn. Select Orchid, v. i., t. 2). Syn., Epidendrum amethystoglossum, Rehb. fil.—A rare and beautiful species, with tail stemlike pseudobulbs some 2½ feet in height, in strong well-grown examples reaching even 3 feet, slender at the base, gradually

thickening upwards, and much furrowed, bearing at the top a pair of oblong-lanceolate, obtuse, coriaceous, dark green leaves, about 6 inches in length, and upwards of 2 inches in breadth. Scape stout, erect, sheathing at the bease, and many-flowered. Flowers large, upwards of 4 inches in diameter. Sepals and petals oblong-ovate, obtuse, nearly equal, white, profusely spotted and blotched with rosy purple. In some examples we have found these blotches often become confinent, thus forming transverse bars. Lip three-lobed; middle lobe spreading, broader than long, narrow at the base, the apex marked with radiating ridges, which are papillose;

colour a deep rich smethyst; side lobes erect, cucultate, and spreading outwards at the points, where they are the same rich colour as the middle lobe, outside white. It bloomsduring May and June, lasting several weeks in full beauty. Native of Brazil. 1862.

Native of Brazil. 1862.

C. amethystoglosss, Robb. fil.; var. sulpheres, Robb. fil. (Gard. Chron., 1866, p. 315).—This is a remarkable and showy variety. Professor Reichenbach, in describing it, says, "The flowers are nearly or quite of as pure a lemon colour as those of Cattleya citrina, and the lip is cream-coloured." It blooms during May and June.

) I address was same profes

Fig. 31.—CATILEYA AMETHYSTOGLOSSA.

C. celetina, Rehb. fil.—A species of great beauty, but of which we have at present seen no figure. "Pseudobulbs nearly terete, furrowed, 12 to 18 inches or more high. Leaves in pairs, oblong-acute, some 8 inches long, and upwards of 14 inch in breadth. Scape terminal, erect, many-flowered. Flowers large, and very fragrant. Sepals ligulate acute, recurved. Petals much broader than the sepals, oblong-acute, all of a beautiful orange green, irregularly blotched, spotted, and streaked with purple. Lip three-lobed; lateral lobes small, somewhat ovate, cucullate, soft rose, with purple lines; middle lobe large, ovate-acute, deep velvety rose, vained and streaked with purple; throat yellow." It blooms during the autumn months. Native of Brazil. 1869.

C. Leddigesii, Lindl. (Bot. Cat., 337).—This is a fine old species, well deserving a place in every collection, if only to keep fresh in the memory the ardent lover and cultivator of plants whose name it bears; independent of this, however; it is a most desirable plant on account of its free-flowering habit and soft delicate colour. Pseudobulbs stem-like, jointed at intervals, furrowed, about a foot high, bearing a pair of leaves on the summit. Leaves ovate-lanceolate, obtuse, coriaceous, about 6 inches long, deep green. Scape terminal, erect, three to five-flowered. Sepals and petals about equal, oblong-obtuse, slightly waved at the margins, pale rose tinged with lilac, and spotted all over with dark spots. Lip three-lobed; lateral lobes convolute; middle lobe spreading,

beautifully crispate in front, light rose, marked with yellow and purpls at the base. It blooms during autumn. Brazil. 1818.

TRICYRTIS HIRTA.

THIS attractive herbaceous plant, although well known in most large collections, is by no means in general cultivation, and is in fact quite new to many persons. The annexed

engraving represents very fairly the clusters of flowers, which rise from the axils of the leaves on the upper part of the stems. The latter usually reach a height of 3 to 4 feet, and bear numerous sessile, clasping, hairy, alternate leaves. The flowers are white, thickly dotted with purple, the divisions of the perianth being slightly recurved. The plant is hardy, and will thrive extremely well in a sheltered border composed of mandy loam and peat; but as the flowers appear late in the

son, the leaves are often by that time shrivelled and present (a very unsatisfactory appearance. For this reason the plant seems to be best suited for pot culture, and it is well adapted for growing in a greenhouse or any structure of a similar temperature. The flowers also are seen to much greater advantage when near to the eye than if the plant occupies a border, where the fine markings of the sepals are quite lost. It can scarcely be imagined what pretty little button holes the flowers make when mounted, and they are also well suited for bouquets, &c. During the time the plant is growing freely and until the flowers are produced abundant supplies of water will be required, but after the flowers have faded water must be given in smaller quantities, only sufficient to keep the soil alightly moist. The pots must be thoroughly drained, and the

soil employed should consist of loam, sand, pest, and a small proportion of leaf soil may be added.

This species of Tricyrtis was originally named by Thunberg

Uvularia hirta, but since Mr. Fortune rediscovered the plant in Japan, and sent specimens to Mr. Standish of Bagshot, the old generic name has been discarded in favour of the one given above. The name Tricyrtis we may remark is derived from two Greek words, and refers to the three sac-like convexities at the base of the outer divisions of the perianth.-L. CASTLE.

Peaches and Nectarines. Last year at the end of the season I tried making small bags of green leno or mosquito gauze and putting them on the fruit, tying the bags with small twine as close to the stalk of the fruit as possible. It succeeded perfectly, and this year I have tried it on a larger scale, and have every reason to be satisfied with the result. No fruit thus covered has been attacked in any way. The bags are 8 inches by 5, and they will do from year to year.—HORACE.

LILIUM AURATUM AT ANTWERP.

I SEND herewith photographs of a Lilium auratum growing in an Azalea bed on the north-east side of a small Oak wood. The bulb was planted three or four years ago and this year has emitted two flower stalks, one of which exhibiting a quite abnormal growth. The stalk is flat and broad (21 inches); in fact it is a stalk composed of five or six brother stalks grown one into the other under one envelope of bark. It forms one enormous head of flowers onewded closely together to the number of 167, head of flowers crowded closely together to the number of 101, and forming a decree mass over 2 feet in diameter. The height of the whole plant is 6 feet. This abnormal growth may interest you and the renders of your Journal. Another Lilium auratum, standing on the east side of a slope in another part of my garden and well protected by Fir trees, had emitted also two big flower stalks enormously high—9 feet. The flowering was much earlier and was magnificent, although each head had no more than twenty-eight or thirty flowers. Small plants are now springing up near the large specimens, which is a sign with me of the old bulbs dying off and being replaced by new bulbs much more numerous. In fact my bulbs generally do not last more than four years in the open borders, when they disappear, but are happily replaced by young ones.

J. EVERAERTS, Antworp.

[We have frequently seen fasciated examples of Lilium auratum bearing many flowers, but never saw a spike more imposing than the one represented in the photographs submitted,—EDS.]

DAHLIAS AT SWANLEY.

AMONGET the numerous plants that Mr. Cannell so well cultivates, the Dahlia receives a large and increasing share of his attention, with corresponding satisfactory results. Having grown an immense number of varieties he has by carefully selecting the best and most distinct acquired a stock which includes some of the best in cultivation. On the occasion of a recent visit I found these plants in excellent condition as regards their flowers, although the growth is not quite so free as in more favourable seasons. Separate quarters are assigned to the different races known as pompons, show, farcy, and bedding varieties, and the original single, but yet pretty, forms are also well represented. Among the latter that beautiful form named Paragon is especially noticeable, although Mr. Cannell has not had it in such good condition this season as when he first exhibited it at one of the meetings of the Royal Horticultural Society in 1878. Readers of this Journal are no doubt familiar with it from the excellent emgraying that appeared very shortly after (vol. xxxv., page 248). It bears some resemblance in form and colour to D. superflux, of which it probably is a variety, but nothing is definitely known concerning its origin. The outer florets are flat, rounded and broad, of a dark rich crimson colour, margined with a narrow hand of a lighter shade the control florets being well densely band of a lighter shade, the central florets being small, densely crowded, and yellow. Another very attractive form, which I know not whether to call a variety or species, is that which was recently exhibited by Mr. Cannell at Kensington under the name of the Cactus Dahlia. The flowers are large, and the florets instead of heingapilled. the florets, instead of being quilled or cupped as in the ordinary form, are all flattened out like the outer florets in most of the single varieties. The colour is a most intense rich crimson. Mr. Cannell obtained the plant from Mr. Cullingford of Phillimore Gardens (under the name of D. Yuarezii), to whom it was sent by the continental nurserymen, Messrs. Ant. Roozen and Son, and that is all I have been able to learn in reference to it. In addition to the above, several others were showy and free-flowering; notably Cervantesii with orange-scarlet outer florets; lutea, bright yellow; gracilis perfecta, crimson; and glabrata, lilac.

The show varieties are very numerous and fine, but I can only give a few brief notes of those that appeared the best at the time of my visit. Toison d'Or, one of Turner's raising, has a neat globular flower, in colour bright yellow; Samuel

Plimsoll, an excellent flower, rich purple lake; Star of the Morning, sent out by Keynes, flowers very large, of a bright orange tint; Sarah McMullen, raised by Rawlings, a good colour, purplish pink; King of Primroses, clear primrose tint; John Sladden, flower of medium size, colour dark maroon; Lady Blanche, pure white; Dr. Moffat, very dark purple. Next I noted a few of the curiously streaked varieties known as fancies. Of these the most distinct were the following :-Robert Burns, flower large, light purple, with streaks of a darker shade; Viceroy, suffused with pink, crimson streaks and spots; Begularity, somewhat similar to the last, but large and the streaks are of a more purplish tinge; Harlequin, very striking, yellow, thickly streaked with crimson; Fanny Sturt, handsome flower, bright crimson, tipped with white; Mrs. Saun-

ders, large flower, pale yellow, tipped with white.

The bouquet or pompon Dahlias are rapidly and deservedly becoming more popular, for there is a neatness in the diminutive flowers that is far more pleasing to many persons than the huge blooms grown for exhibition. Sambo is a fine dark maroon; Little Besuty a good white; Rigolette, bright dark ramson; Estate Bessly's good white; Rigolette, Bright dark crimson; Barcelona, very neat, bright crimson; Lydia, bright yellow; and Little Helena, a purplish tinge. Of the bedding varieties the best for general purposes are Vivid, scarlet; Crimson King; Dauntless, orange; Nelly, white tipped with purple; Ethel Newcombe, clear pale yellow; John Laing, scarlet-crimson; and High Sheriff, of the darkest maroon

There were many other plants worthy of notice, especially the Marigolds, Antirrhimams, Asters, and Hollyhocks, of which Mr. Cannell possesses excellent strains; but for the present I must confine myself to the Dahlias, which amply repaid me for my visit.—R., Surrey.

PLANTS IN FLOWER AT BIRDHILL HOUSE, CLONMEL.

THE visitor is always and at all seasons sure to find many things to interest him here-many floral beauties to admire, while Mr. Gough or his gardener are always ready to explain details of cultivation. Of the many lovely plants now flower-

ing I noted the following indoors—

Lilium lancifolium.—Of this there is a wonderful display. Half a dozen plants in 10-inch pots fill the entire end of the conservatory, each bearing from thirty to sixty fully developed flowers of the richest tints of colour, softly shaded into each other. The plants were plunged in coal ashes during the summer if we had a summer—behind a north wall, and protected from gusty winds. There they were left until showing bloom. The outdoor Japanese Lilies were also very fine, and even still more floriferous in many localities. There are still

fine specimens blooming here of L. Auratum.

Vallota purpurea.—A few early bulbs of these are conspicuous by their fine bright crimson blooms, while later bulbs will flower for months to come with cooler treatment. I saw them flowering freely in cottage windows last year in Sussex.

Coleus.—Mr. Gough's collection is large and very select, containing many of the rare new introductions. Notwithstanding the absence of senshine this year the colours came out very brilliantly, especially Pictus, Multicolor, Duchess, Shah, Lady Burrill, Rubra, Brilliant, &c. When once established they grow and make fine stocky plants with frame or greenhouse culture.

Glowinia crassifolia.—This is a fine plant, the richness and soft colouring of which baffles description. Of three dozen seedlings of the present year obtained from one package of Messrs. Suttons' seed many are now throwing up fine blooms of the most gorgeous tints. The temperature of the stove is kept pretty steady at 70°, with that moist atmosphere in which they luxuriate. This year I have found it useless to try to bring them to perfection except under somewhat similar treatment.

Geenera Cooperi.—The profuseness of bloom of two of those magnificent stove plants with their fine brilliant scarlet tubular flowers exceeded anything I had hitherto noticed of the same kind. I am certain each contained 250 fully expanded flowers, the brilliancy of which festooned around quite eclipsed Vincas, Fittonias, Dendrobiums, and even a fine Eucharis amazonica within their vicinity.

Tuberous Begonias.-These are a speciality at Birdhill, and the bloom at present inside and out notwithstanding the peculiarity of the season, is said by experts to be one of the finest in Ireland. Mr. Lonegan, Mr. Gough's intelligent gardener, has succeeded in raising many novelties as seedlings, a semi-double not named of a very rich hue being very noticeable. Notwith-standing the prolonged wet weather those bedded out continue to flower profusely, and with their wonted grace and brilliancy. As to their accommodating nature referred to in a previous aumber by me, I may mention they have been satisfactorily used here as basket plants with fine effect. Of Orchids deserv-

ing more than a passing notice— Odontoglossum grando.—A small plant with three stems and five flowers on each appeared very handsome, and seemed to deserve the fancy name of the "Tiger Flower" from the

analogous stripes on the back. It was grown in a 6-inch pot, and has been blooming for the past five weeks.

Vanda suaris.—Two large flower stems with eight flowers on each, of a fine creamy white crimson. The blooms last very long, and it seems deserving of the preference it generally receives as an exhibition plant.

Oncidium papilio (The "Butterfly Orchid.")—This is no misnomer, for if perched on a flower the resemblance would be They are sometimes grown in pots. Mr. Lonegan

prefers blocks for it. The flowers last very long.

Odontoglossum Uro-Skinneri.—This may almost be said to exceed the best in continuous blooming habit. Some three months since I observed the same specimens flowering finely that I note to-day. Extreme cleanliness was most conspicuous everywhere, walks, stages, glass, but particularly the plants. In fact even a green fly was not to be observed. The success was proportionate.—W. J. M., Clonmel.

DESFONTAINIA SPINOSA.

I FIND this plant perfectly hardy here on the west coast of Argyllshire. I turned out a small pot plant six years ago. It is now upwards of 5 feet high and 12 feet in circumference, and has stood without any protection; and even during last winter's severe frosts, lasting almost consecutively for three months, did not lose a twig. It continues to grow freely and to produce a succession of flowers on the young wood as late as November. It seems to like a damp climate and cool moist soil. I would suggest growing it in England in a hardy fernery in the lightest and best ventilated part of the house, where it would probably flower till Christmas. It is very easily propagested either by leyers or cuttings.—A. DUNLOP ANDERSON, Ardsheal, Appin, N.B.

BOSA POLYANTHA, ITS IMPORTANCE AS A STOCK.

Now that Briars are becoming more and more scarce, and their prices rise accordingly, I deem it necessary to call the attention of horticulturists to a new Briar of very vigorous growth and easy to raise, which characteristics entitle it to be

further known and brought into use.

It is of recent introduction, and indigenous to Japan; its flowers, which bear a certain resemblance to the common Briar, are nevertheless smaller and paler; they are single, sweet-scented, and grow in clusters of between thirty and forty, succeeded by obovate fruits about the size of the kernel of a cherry. M. Carrière, who gave a description of Rosa polyantha, Sich. and Zuco., in the "Revue Horticole" of 1st July, 1876, states that this Rose forms sterile branches about 6 feet high. He also cites the result of some seedlings, some of which had rose-coloured flowers, others yellow, and in some cases they were double; others again had white, or rose and white, or yellow flowers. The Botanic Garden at Bordeaux received some seed from Japan in 1873, which directly upon their arrival were sown in light soil. Ten young plants of vigorous growth were the result. The second year their vigorous growth was even more apparent. Since that time repeated trials have proved conclusively that this Rose can with advantage of the second year their vigorous growth was even more apparent. tage be substituted for the common Brier as a stock.

Suppose you have a clump of Rosa polyantha. In November, after first cutting off all the shoots, which should be carefally laid aside, pull the clump to pieces, preserving if possible a heel to each bit, and if provided with a few rootlets so much the better; the strongest pieces are then planted out far enough apart to allow of their being trained as standards and budded the following summer. The smaller and misshaped prices are next out into needful lengths and planted as stocks for half-standards and dwarfs. Lastly, the branches and bits of wood, even to the smallest twigs, are made into cuttings, which root as easily as couch grass. These cuttings will the following season, and the year after that, make vigorous plants

to form new plantations. The strongest roots found on dividing the plants can be potted, grafted, and placed on a hotbed, where they will speedily "take" and push vigorously. These grafts generally succeed in the proportion of 80 per cent.

The common Briar (Rosa canina, L.) roots but sparingly from cuttings, and takes a long time to raise from seed. I would therefore advise all interested in the cultivation of Roses to plant the Rose polyanthe, considering that a cutting of moderate size will attain ample size to be budded the same season as a dwarf, or the year following as a standard or half-standard.

A German cultivator recommends Elizabeth Vigneren as an excellent Rose for forcing purposes, especially as standards on the Briar in pots.—A. CAILLE, Botanic Garden at Bordeaux. —(Journal des Roses.)

DAVALLIA PARVULA.

This charming little plant is a native of Borneo, and is deserving of a place in every fernery, although at present it is not so frequently met with as might be expected. The rhizome is slander and creeping, as in the other species, but the fronds are very diminutive, finely divided, and dark green, while the height of the entire plant rarely exceeds 3 or 4 inches. It may be grown in a Wardian case or under a large beliglass. and requires a small portion of the stem of a Tree Fern to ching to; over this the rhizomes will run freely, producing the delicate and pretty little fronds. Any approach to stagnation in the soil or on the fronds must be carafully avoided or they will speedily damp off, but at the same time a deficiency of moisture is equally fatal. For this reason a Wardian case is despecially adapted to its requirements, as the suitable degree of moisture can easily be maintained. The pan must be well drained with clean potsherds, the largest at the bottom and a layer of smaller pieces over them. The soil should consist of fine fibrous peat with a good proportion of silver sand. If the Fern stem intended to support the plant is placed in an erect position the water may be applied at the top and allowed to trickle down the sides; sprinkling water over the fronds too freely is not advisable. A temperature of 60° to 76° is necessary to obtain it in good condition.—FILIX.

MANURE FOR ROSES.

OF the many difficulties which present themselves in connection with Rose-growing to anyone situated, like myself, in the neighbourhood of a large town, perhaps not the least is that of procuring suitable manure at a reasonable price. I think all are agreed that nothing can beat good farmyard manure, cow or pig dang being the best. But I find it next to impossible to procure it, most farmers being compelled under a resulty not to sell but to nee it when their land. The Management of the sell but to nee it when their land. a penalty not to sell but to use it upon their land. The Manchester Corporation have helped us to solve the difficulty by placing upon the market a concentrated manure, which, after a fair trial (and as I have no interest in the sale I may be supposed to give my impartial judgment), as a substitute for farmyard manure I know of no equal.

The manure is in a granulated form, specially made thus at the request of a large number of influential farmers. made from urine and solid excrement, mixed with blood, bones, fish, and dried animal matter. In disposing of this manure the Corporation of Manchester have a double object in view. In the first place, by disposing of their products in this form they are enabled to utilise human fœces, putrid fish, and animal matter, the blood and refuse from slaughter houses, and dead animals, which are so difficult in all towns to dispose and dead animals, which are so direct in all towns of dispose of; at the same time they are preparing a valuable manure suitable for all crops, which is correyed to the farmer at a cheap rate, and applied to the land with ease and economy. I should add that it is packed in bags (which are not charged for) and delivered at any railway or canal station in Great Britain. This, I think, would be an excellent manure for "WYLD SAVAGE."—M. CHESTER.

THE CUCKOO.

THE following particulars respecting the habits of the Cuckoo may be interesting to some of your readers. About the end of June, 1877, one of our gardeners found a young Cuckoo in a pied Wagtail's nest that was built in a Pear tree that is trained against the garden wall. The eggs of the Wagtails had been sucked and thrown out. The bird grew very fast, and the

parent Cuckoos came on to the top of the wall nearly every day to see the young one, and when ready to fly it perched in some trees close by and the old Cuckoos with it, the Wagtail

still feeding it, until at last they all disappeared.

This year the pair of Cuckoos were again about the garden, but we found no nest, though we could see the Wagtails were very busy; but about August 15th we saw a fine young Cuckoo sitting on the hurdles close to the house and the Wagtail at work feeding it. It remained several hours, the little bird feeding it with insects every few minutes. It was most curious to see the great red mouth open enough each time to swallow the Wagtail bodily. All the birds are very tame, as they are never disturbed, and the cock Cuckoo will sit only a few yards from me, singing all the while.—HABRIET E. FRANK, Ashbourne Hall, Derbyshire.

WORK FOR THE WEEK.

FRUIT HOUSES

Vines. — Fermenting materials should now be prepared for placing on outside borders at least a fortnight previous to closing the houses in which it is intended to have ripe Grapes in March or early April. Two parts of Oak or Beech leaves with a third of fresh stable litter thrown into a heap, moistened if necessary, and turned over a few times, will afford a more durable heat than dung. Fermenting material should also be prepared for placing inside the former time instants should use to be pleafed to pacing instants the fouse, which will aid the Vines in starting and lessen the necessity for fire heat. If the earliest Vines have been pruned the house should be thoroughly cleansed, the border being top-dressed as before advised, and the house kept as cool as possible. Vines intended to be started early in December should be pruned (if not intended to be started early in December should be pruned (if not already done) without further delay, so as to allow them some weeks of rest before starting. The earliest Vines in pots start more freely if a slight bottom heat can be afforded them; a bed of leaves with the addition of a third part of stable litter will maintain a mild lasting heat. The temperature at starting the Vines should not exceed 55° by artificial means, but when the buds show signs of breaking it may gradually be increased to 65°. The canes should be slung in a horizontal position to induce them to push their buds evenly throughout the length of the rods, syringing them three or more times a day. Vines that have been ripened early, pruned, and had about six weeks' rest may be started at once. The present is a good time to lay in a stock of materials for them three or more times a day. Vines that have been ripened early, pruned, and had about six weeks' rest may be started at once. The present is a good time to lay in a stock of materials for forming Vine borders. The top three inches of a pasture where the soil is of a rather light loam (and if it overlie gravel all the better) is suitable for Vines, and should form the staple of the compost. Late houses in which the Vines were judiciously forwarded by fire heat in the spring will probably now have crops of ripe well-coloured Grapes, which will keep much better than those that still require heat. Liberal ventilation on all favourable occasions will be required, and as the foliage is matured the temperature may be allowed to fall to a minimum of 50°. Mats or a light covering of clean dry straw placed on the inside borders will prevent the rising of moisture. The Grapes should be looked over twice a week for the removal of decayed berries, but if thoroughly ripened they will give little trouble. A supply of fern where the common bracken is plentiful should be cut for covering up late house borders for the winter. A good covering of bracken is quite equal if not superior to litter as a protection. Young Vines not unfrequently are disposed to break into another growth, which must be checked by moderate stopping, facilitating the ripening of the wood by keeping a high and dry temperature through the day, shutting off the heat and opening the ventilators at night. Late Grapes not yet ripe must have fire heat briskly by day with a free circulation of air, and the temperature must not be allowed to fall below 66° at night, and to assist the ripening of the wood keep lateral growths closely stooped. below 65° at night, and to assist the ripening of the wood keep

lateral growths closely stopped.

Peaches and Nectarines.—In the earliest house the trees will be at rest, and they should be pruned and tied to the trellis after being dressed with an insecticide, the whole house having a thorough cleansing. The inside border must not lack moisture. The trees in midseason houses should be attended to before the heaves fall, and if the trees be too vigorous root-pruning or lifting the trees should be resorted to. Efficient drainage must be provided, and any strong roots should be shortened back, employing the soil rather dry so as to admit of being rammed firmly. Turfy learn rather strong, with the addition of a tenth of chalk or lime rubbish and a twentieth of charred refuse well incorporated, forms rubbish and a twentieth of charred refuse well incorporated, forms a suitable material for renovating old or making new borders. No manure should be added, it is best given as a mulch and in a liquid form. New borders should be drained to a depth of 9 to 12 inches, and 2 feet depth of soil is ample. The earlier the trees are planted after the leaves show indications of falling the better, as fresh rootlets are produced at once. Except for affording fruit very early—when a tree or two of Early Beatrice or Early Louise may be planted—the very early Peaches are not comparable to Hale's Early. Early Grosse Mignonne, A Bec, and Dr. Hogg are the best of the early kinds; Grosse Mignonne, Royal George,

Violette Hative, and Noblesse are fine old Peaches that force well; Bellegarde, Barrington, Stirling Castle, and Late Admirable make a dozen of the best varieties. Lord Napier is the best of the early Nectarines; Elruge, Violette Hative, Pine Apple, Stanwick, Elruge, and Albert Victor are all that is necessary in Nectarines. They, with the Peaches, are named in order of ripening, and as suitable

for early, midseason, and late forcing.

Cherry House.—If it is intended to plant any trees it should be Cherry House.—If it is intended to plant any trees it should be seen to as soon as the leaves begin to fall. The Cherry—indeed, stone fruits generally—thrive best in a calcareous soil. Turfy loam with a tenth of old mortar rubbish, or a sixth of road scrapings, thoroughly incorporated answers very well, the border being about 80 inches deep and thoroughly drained to a depth of 9 inches, and about 6 feet wide, which is ample for trees grown under glass. Black Tartarian and May Duke are the best varieunder glass. Black Tartarian and May Duke are the best varieties, but the yellow forms an excellent addition to the desert when fresh fruit is not over-plentiful; Early Jaboulay, Elton, and Governor Wood are first-rate. The lights having been removed they need not be replaced for a month or six weeks, the old surface soil being removed without injury to the roots and replaced with fresh compost, that above named answering with the addition of a fourth of manure. Trees in pots required to be shifted into a larger size should be attended to at once; and those not requiring to be so treated should be turned out of the pots, removing a few inches of soil from the base of the balls, cutting back the roots, and replace the soil removed with fresh losm, back the roots, and replace the soil removed with fresh loan, adding about a tenth of old mortar rubbish and a sprinkling of half-inch bones, good drainage being provided. Remove the surface soil, replacing with the above compost, adding a fourth of well-decomposed manure. Afford a good watering, and place the trees where they can have plant of air.

trees where they can have plenty of air.

Orchard House.—Trees that require repotting should be shifted into pots about 2 inches larger before the leaves have fallen, disinto pots about 2 inches larger before the leaves have fallen, disentangling the roots at the sides of the ball as well as those at the base, and removing the surface soil, any long roots being cut back and the fresh soil rammed as firmly as possible. If it is not desired to place the trees in large pots the sides of the balls may be reduced about an inch, the roots cut back, and returned to pots of the same size. It is important that good drainage be provided. Trees that it may only be desirable to top-dress should have the surface soil removed to a depth of 3 or 4 inches, replacing with freeh material Turfx, vallow, or rather strong loam with about with fresh material. Turfy, yellow, or rather strong loam with about a fourth of well-decomposed manure answer well if thoroughly incorporated with the loam; and if there be an addition of charred incorporated with the loam; and if there be an addition of charred refuse, about a tenth, and crushed bones, a twentieth, it will be an advantage. A good watering should be given. Any trees from which the fruit has not been gathered must not be yet disturbed at the roots. Pears, Plums, and Apples mature the buds better when placed outside in a sheltered situation than they do under glass, but it is a mistake to place them outside under the impression that the wood is thereby ripened, whereas heat and a dry atmosphere are required to effect that, and is best accomplished under glass. Trees, however, may be placed outside when the wood is ripe with advantage, but the pots must be placed on a hard bottom. Peaches and Nectarines should have all the light and air possible. and air possible.

FLOWER GARDEN.

FLOWER GARDEN.

Some of the subtropical plants—such as Aralias, Acacia lophantha, Abutilons, Cannas, Melianthus, Dracenas, Mussa, Wigandias, &c.—lifted carefully with good balls, potted and placed in a close moist house, and frequently syringed, soon become established, and are very useful for furnishing conservatories, corridors, halls, &c., being much more suitable for such purposes than choicer and more delicate plants. All tender plants which it is desirable to save should be removed from the beds before they become affected by frost. Pelargoniums grown for their foliage should only have some of the leaves removed, but those grown for their flowers may be cut-in rather closely and the roots trimmed, so as only have some of the leaves removed, but those grown for their flowers may be cut-in rather closely and the roots trimmed, so as to allow of the plants being potted in small pots. Very little water will be needed for some time, but it is necessary that the plants have light airy structures and a temperature of 40° to 45° by artificial means. As soon as the beds have been cleared attention of the control of plants have light ary structures and a temperature of a was by artificial means. As soon as the beds have been cleared attention should be at once turned to refilling them, either with dwarf shrubs, spring-flowering plants, or bulbs. Snowdrops, Crocuses, and Squills should be employed for edging the beds or borders, and in employing the Crocuses it is desirable to keep the colours separate. The Squills also should be kept separate, employing the early-flowering, as Scills sibirica, bifolia, and amoena, which prefer a sandy soil. Select those varieties of bulbs that are the brightest and most distinct in colour, such as in Hyacinths Robert Steiger, red; Amy, crimson; Madame Hodson, gink; Grand Vainqueur, white; Blanchard, white; Grandeur a Merveille, blush; Grand Lilas, pale blue; Mimosa, dark purple; Blen Mourant; and Meyerbeer, yellow. In Tulips Bacchus, crimson; Crimson King; Pottebakker, reddish violet; Thos. Moore, orange; Rose Gris de Lin, rose and white; Proserpine, dark rose; Keizer Kroon, scarlet, margined yellow; Cramoisie Royale, rose; Comte de Mirabeau, white; Standard Royal, white, feathered rosy crimson; Rosa Mundi, white, shaded rose; Queen of the Violets; and Yellow Prince. There is, indeed, no need of empty beds in winter

and scanty bloom in spring, as Winter Aconite and Snowdrops are rapidly succeeded by Primroses, Squills, Aubrietias, Myosotis or Forget-me-nots, Daisies, Pansies, Arabis, Gentians, Hepaticas, Alyssums, Wallflowers, Anemones, and perennial Candytufts (Iberis). To add to the beauty of the beds in winter the decorative (Iberis). To add to the beauty of the beds in winter the decorative value of shrubs is but little turned to account, and such plants as Erica herbacea carnea, Euonymus radicans variegatus, Golden Thyme, and Vinca elegantissima serve as edgings to taller plants, such as Hollies and Tree Ivies, Osmanthus, Cupressus, dwarf Rhododendrons, Japan Euonymus, Skimmia japonica, Thuja aurea, Retinosporas, Boxes, Aucubas, Andromeda floribunda, Cryptomeria elegans, and many others that separately or in combiton with flowering plants produce a cheery effect from the time of the with flowering plants produce a cheery effect from the time of the removal of the summer occupants.

PLANT HOUSES. Store.—Allamandas intended for early flowering, and which will consequently require to be cut back about the new year, should now receive no more water than will just keep them from flagging, so as to check growth sufficiently to insure well-ripened wood. Any plant of Clerodendron Balfourianum, Bougainvilles glabra, required to have the growth ripened-up should have plenty of light and a moderately dry atmosphere, which is more satisfactory than subjecting them to a low temperature. Roof climbers should be well thinned out or cut back so as to allow plenty of light to reach the plants beneath. Some Passion-Flowers are very light to reach the plants beneath. Some Passion-Flowers are very fine at this season, notably Passiflora kermesina, P. cardinalis, P. Munroi, P. princeps. Bougainvillea glabra as a roof climber affords a grand display late in winter, and Ipomæa Horsfalliæ is showing its rich flowers, so that these and others as Manettias, Jasminum Sambac that flowers during the autumn or winter, must not be cut back or be reduced too much. This is the best time in the year to destroy mealy bug and white and brown scale. A wineglassful each of methylated spirits and turpentine to a gallon of water is a very good mixture, but we are now using nicotine soap with good effect at a strength of 6 ozs. to 8 ozs. to a gallon of water at the persure of 100°. It removes white scale, mealy bug, and brown scale, leaving the plants clean. It has no unbug, and brown scale, leaving the plants clean. It has no unbug, and brown scale, leaving the plants clean. It has no un-pleasant smell, is pleasant to use, and efficacious, whilst not in-juring the foliage. Stove-flowering Begonias should have every attention to insure their flowering strongly, affording liquid manure occasionally. They will produce a quantity of bloom through the winter that will be very acceptable for cutting. Medinilla magnifica to insure its free flowering should be kept at the driest end of the stove, and have no more water than will the driest end of the stove, and have no more water than will keep the leaves from suffering. Stephanotis floribunda should not be pruned at this season, but kept with its shoots near to the glass. Bouvardias to flower freely in winter must be placed near the glass in a stove or an intermediate house with a temperature of 55° to 65° by artificial means, supplying liquid manure about once a week. Richardia æthiopica should be placed in a house near the glass with a temperature of 55° at night and he well supplied the glass with a temperature of 55° at night, and be well supplied with water and liquid manure occasionally. A few roots of Lily of the Valley should be started. Plants that were employed for gentle forcing in spring and kept growing under glass until the growths were complete, and having been hardened-off outdoors, will be in fine condition, flowering freely if plunged in bottom heat of about 90°.

Orchids.—Some decline must now be made in the temperature-Orchids.—Some decline must now be made in the temperature— a mean of 70° by day and 60° at night for the Rast India house; Cattleya house, 65° by day and 55° by night; and for the Odonto-glossum house 55° by day and 45° at night is desirable. Very little ventilation will be necessary except on mild days. The atmospheric moisture must also be reduced, and syringing over-head discontinued. Calanthes are producing their flower spites, atmospheric moisture must suiso be reduced, and syringing overhead discontinued. Calanthes are producing their flower spikes, and should be kept near the glass and have encouragement in the shape of heat and moisture, and have the leaves kept clean by sponging. Zygopetalums and other plants starting into growth must be kept moderately moistened, placing them in the most favourable part of the house, where they can have plenty of light and moisture, repotting if necessary, or renew the surface with fresh material. Dendrobiums, Cattleyas, and other plants, the growth of which is complete, will require very little water. Phalenopees must be very carefully watered, as the leaves are liable to decay. Keep the glass and woodwork as clean as possible, giving the plants a thorough cleansing, neatly staking young growths. Slugs are very destructive to the tender growths and flowers, and should be sought after by lamplight. Plants in flower should have a drier atmosphere, as they last much longer in a somewhat dry atmosphere than in a moist one, and 50° to 55° most will bear without injury when in flower. Odontoglossum grande, Pleiones, and Vanda cærulea are fine at this time of year, also Oncidium macranthum, O. flexuosum majus, O. aurosum, O. incurvum, O. tigrinum, and O. ornithorhynchum.

TRADE CATALOGUES RECEIVED.

W. Bull, Chelsea.—Illustrated Catalogue of New and Rare Plants.
William Rumsey, Waltham Cross, N.—Catalogue of Roses,

George Cooling, Bath.—Catalogue of Roses and Fruit Trees.

Boulton & Paul, Norwich.—Illustrated Catalogue of Horticultural Buildings and Hot-water Apparatus.

Frederick Gee, Biggleswade, Bedfordshire.—List of Vegetables.

Auguste Van Geert, Gand, Belgium.—General Catalogue of

Elwanger & Barry, Rochester, N.Y.—List of Strawberries.

Jean Nuytens Verschaffelt, Gand, Belgium.—General Catalogue of Plants.

TO CORRESPONDENTS.

* All correspondence should be directed either to "The Editors" All correspondence snould be directed either to the random or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

SHORTHAND (G. B.).—The best system is Pitman's. A book of instructions, price 1s. 6d., may be obtained from R. Pitman, 30, Paternoster Row, London.

SEEDLING ANTIRRHINUMS (\overline{W} . C.).—They are good and in great variety, the self, spotted, and striped flowers being all alike attractive.

GLORE DE DIJON ROSE FOR BEBS (Busy).—It is an excellent variety for pegging down in large beds, but if weaker growers are planted in the same bed it is apt to overgrow them. It is worthy of a bed to itself, and can be kept in order by judicious prunings. As your old specimen gets worse each year we should destroy it and plant young healthy plants.

IXIAS AND SPARAXIS NOT FLOWERING (Iden).—As the plants grew freely but did not flower you have probably kept them too close during some period of their growth. They require abundance of light and air to prevent the leaves being "long, alender, and delicate."

REBUILDING FLUES (Someract).—Mortar made of lime and ashes will do for setting the bricks. Plaster the inside of the flues not more than half an inch thick. Ask any bricklayer about plastering.

RHUBARB PLANTING (Celewayo).—Plant at least 3 feet from the hedge. The quantity of Potatoes you will require for planting an acre depends on the size of the sets and the distance between the rows and sets.

CLUB-ROOT (J. N. B.).—Charcoal dust spread about half an inch deep upon the surface and just mixed with it by the point of a spade, it is said, prevents the occurrence of this disease. Soot, we have reason to believe from a slight experience, is as effectual as charcoal dust. Judging from theoretical reasons we might conclude that it would be more specifical; for, in addition to its being, like charcoal, finely divided carbon, it contains sulphur, to which insects also have an antipathy. A slight dressing of the surface soil with a little of the dry hydro-sulphuret of lime from the gasworks would prevent the occurrence of the disease by driving the weevils from the soil.

from the soil.

GOOSEBERRY CATERPILLAR (F. R.).—Open a trench I foot in depth at the extremity of the roots, and then sorape or shovel the surface soil from over the roots for nearly 3 inches in depth into the trench in the hope of burying and destroying the chrysalis, which probably are not embedded much desper. The paring of soil should be well trampled down, and the occasion may be seized for manuring the roots in the circle or line excavated. Sait and soot might be used to cover the parings before trampling them down, or other strong matters which are at once fatal to insect life and a manure to the bushes. An effectual method for preventing the caterpillar was practised by the late Mr. Robert Hogg of Bogan Green, Berwickshire, which consists in simply covering the surface of the ground round the bushes with a layer of bark from the tanyard either in the autumn or early in spring; and this seems to have such an effect on the insect in its chrysalis state as effectually to destroy it.

Various (Puddle).—Continue to afford your Camellias cool treatment

VARIOUS (Paddle).—Continue to afford your Camellias cool treatment until the spring, when you may repot such as require it. The Coleuses must be placed in a stove temperature during the winter, or you will not be able to preserve them. They had better be cut back, as they will then make fine plants next summer. The Amorphophallus produces its spathe and spadix from the root of the plant and not from the leaves.

SAND OFF ROADS (Frank).—So far from the sand being injurious te plants you cannot employ a better substance for mixing with potting soil. You have been very wrongly informed.

LISTS OF BRITISH PLANTS (F. T. F.).—Lists of the rarer plants found in Cornwall are given in the guide books, and a list of the flowering plants alone would be very imperfect indeed. Probably a Flora of Cornwall, including the Ferns, Moeses, Hepaticas, &c., might find a moderate circulation. If "F. T. F." will correspond with Mi. W. Curnow, Pembroke Cottage, Newlyn Cliff, Penzance, he will be able to obtain further information on the subject.

Cliff, Penzance, he will be able to obtain further information on the subject.

LILIUM AURATUM AFTER FLOWERING (Two-and-a-half-years Subscriber).

—The plant should be kept in a light postion until the follage turns yellow, merely supplying sufficient water to keep the soil moist. When the follage has fallen and the stem yellow, turn the plant out of the pot, remove the soil from above the bulb and any soil not occupied by roots, and twist the stem off. Drain the pots well, place the bulb with its roots in the centre and so that its crown will be about 2 inches below the rim of the pot, potting moderately firm, employing a compost of two-thirds fibrous loam and a third of sandy fibrous peat, with a fourth of leaf soil or thoroughly decomposed manure. The plant may be wintered in a pit or house from which frost is excluded, having just sufficient water to keep the soil moist. When growth takes places a light airy position must be afforded, and the water supply increased with the growth, top-dressing the surface to within half an inch of the rim of the pot when the growth is 6 inches above the rim of the pot, employing the same compost as advised for potting. Supplies of weak liquid manure about twice a week when the plants are in free growth and until the flowers expand will be advantageous.

The Bilberry $(E.\ A.)$.—You will no doubt find it growing on the Surrey hills from Reigate to Guildford, and also on the Sussex downs.

VARIETIES OF MRIONS (R. S.).—The following varieties would probably suit you:—Colston Bassett, Bromham Hall, Dell's New Hybrid, Read's Scarlest Heab, Victory of Bath, Trentham Hybrid, Cox's Golden Gem, and Hero of Bath. Sow the seeds early in the year at different periods to afford a succession. Bollisson's Telegraph Cucamber is one of the best for general purposes.

POTTING CYCLAMENS (A Lady).—The corms have been potted too deeply. They should not be more than half inserted in the soil, as when they are covered with soil to the crown the leaves and flower stems are apt to damp off. The compost you employ is suitable for them.

TROP. ZOLUM JARRATTI (Idem).—Pot them at once in light fibrous loam and a third of leaf soil, inserting them about an inch deep. Place the plants in a greenhouse, watering only to keep the soil moist, and assign them a light airy postion. Being climbers they will need a wire trellis or other means of support.

BRIABS FOR ROSE STOCKS (*Idem*).—The stocks should be secured so soon as the leaves fall. The best time to secure and plant them is from the middle of November and early December, or the early part of the winter. Autumn-planted stocks succeed very much better than those planted in spring.

STANDING CAMELLIAS IN SAUGERS FILLED WITH SAND (A. B. C.).—
Although a cool bottom—as that of stone or slate shelves, or it may be
gravel—is preferable to stand the pots upon, a damp bottom is not by any
means essential, as Camellias succeed admirably upon a stage. We should
have an inch thickness of gravel to stand the pots on, so as to enable the
water from the pots to pass away quickly. Tulips succeed admirably in a
compost of turfy loam with the turf well reduced, and a fourth of welldecayed manure thoroughly incorporated with the loam, adding about a
sixth of sharp sand.

RAISING SOLANUM FROM SEED (*Idem*).— The Solanum is probably capsicastrum, which may be raised from seed sown early in March in gentle heat. Pot off the seedlings when large enough to handle, and grow them on in a greenhouse well exposed to light during summer. They will flower and fruit the first year, but more freely as the plants become older.

PRUNING THE MEDIAR (P. D.).—Proceed on the same system as you would with a Pear tree. Thomson's "Manual of Fruit Culture" would probably suit you.

AURICULAS (E. F.).—The "Garden Manual," published at this office, price 1s. &d., or by post 1s. &d., contains full instructions on the subject of Auricula growing. The following varieties are very good:—Green-edged: Fairy Queen, General Havelock, George Lightbody, Lovely Ann, and Imperator. Grey-edged: Alma, Colonel Champneys, Competitor, Lancashire Hero, Richard Headly, and Robert Traill. White-edged: John Waterston, Robert Burns, and True Briton. Selfs: Blackbird, Charles J. Perry, Meteor Flag, Metropolitan, Negro, and Riffeman. Alpines: Black Prince, Colonel Scott, Diadem, Dolly Varden, Indian, John Leech, King of the Crimsons, Masterpiece, Rubens, and Triumphant.

NAMES OF FRUITS (M. D. D.).—We cannot spare space for each lists as you need; select lists are included in our "Fruit Gardening for the Many." We will send it if you enclose 41d. in postage stamps with your full address. (Mrs. E. Wyld).—The Cherry Plum (Prunus Myrobalana). (S. M. W.).—I, Swan's Rgg; 2, Vicar of Winkfeld; 3, Figure do Raples; 4, Too small, and cannot be identified. (S. Mace).—We do not recognise the fruit sent as any variety known in general cultivation.

NAMES OF PLANTS (F. T. F.).—Orebanche major. (J. O.).—Your Fuchsia is much like some others already in cultivation, and is not an improvement on them. The Fern is Davallia tenuifolia var. stricta. (S.).—It is a species of Stapelia, but we cannot name it from such a fragment. (R. P.).—The specimen was too crushed to be recognisable. (A. M.).—The Fern is Woodwardia radicans. (F. T. F.).—I, Juncus uliginous (Bog Rush), a viviparous form which happens frequently to this plant in very moist situations, and particularly so in wet seasons like the present one. It appears to have the power of bringing forth young plants, occasioned by the non-perfecting of seeds. 2, A species of Caliltriche (Water Stawort), but in the absence of specimens in fruit or seed it is impossible to determine the species; 3. Ruspia maritima (Sea Ruppia). (A Suberther).—I, Resembles Begonia biserrata; 3, Begonia Dregei; 3, A variety of Godetia; 4, Apparently Sedum spectabile; 5, Sedum Sieboldii; 6, A Saxifraga, but the specimen was not sufficient to identify the species; 7, Campanula isophylla. (H. S.).—Phalaric canariensis. (Major L. Forbes).—I and 2 are varieties of Acer platanoides. The other specimen is Populus canescens. (F. Walker).—I, Oxalis corniculata rubra; 2 appears to be a Sisyrinchium.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

WHITE MUSTARD AS A FOOD AND FALLOW CROP.

This crop has been for many years recognised by the experienced farmers as a valuable addition to the green crops formerly in use, and it is good either to fised sheep or to be ploughed in as a green manure. Its cultivation for either purpose has lately rather fallen off in the presence of other green crops, such as vetches, &c., and owing to the general use of artificial manures. Some persons have been deterred from sowing it, as it is sometimes confounded with the black or brown mustard. The white mustard, however, is that which is grown in our gardens to use as a salad, and is the Sinapis alba; the brown mustard being the Sinapis nigra of Linnesus. The black mustard may well be avoided

by the home farmer who wishes to keep his land clean, as the seed of this plant if allowed to come to maturity and fall out upon the ground, will come up in the future to the damage of the cereal crops; for, like charlock seed, it will remain in the land for an indefinite time and retain its vitality. White mustard, however, is a much more harmless and useful plant, for in the event of its shedding the seed it germinates so quickly, and is so easily killed by frost, that when saved as a seed crop but few plants will be found in the succeeding crops after an ordinary winter. White mustard will grow upon all soils provided the climate is favourable; still, like most other green crops, its luxuriance of growth will be in proportion to the fertility of the soil. In addition to its growing upon all ordinary turnip and wheat land, it is found to flourish greatly upon peat soils as well as upon very tenacious clays if carefully cultivated and the land made very fine on the surface, for a good tilth like that required for turnips is essential to its successful cultivation.

We usually sow from 16 to 18 lbs. of seed per acre, and it is best to sow the seed broadcast by Bennett's hand machine. In order that the seed may all be buried at a regular depth the ring roller should go over the land before sowing the seed, as it will then fall into the little grooves made by the rings of the roller. When chain-harrowed a single tine the seed will be buried in the best manner to insure its germinating with regularity. It is, however, extremely important that the ground should be moist at the time of sowing, otherwise if the land is dry and cloddy the seed will remain in the land without germinating until the weeds gain the ascendancy. The time of sowing will vary according to circumstances, and may be done as the crop will be required from the 1st of May until the 1st of September; and if the autumn proves mild a fair crop for ploughing-in may be obtained, or for feeding sheep, if upon dry healthy land after the latter date. This crop is often sown instead of stubble turnips after a crop of wheat or early cats, and when either fed-off or ploughed-in will forward the land in condition for a succeeding crop.

This subject seems naturally to be divided into two points, first the feeding off the crop by sheep on the land, and secondly the ploughing-in the produce as a manure, and at the same time smothering the weeds and likewise cleaning the land, so that by the repetition of the crop and the ploughing and tillage consequent upon it the land may not only be measured but clean fallowed simultaneously. First, for sheep mustard is a healthy food, and more especially for ewes in lamb at the fall of the year, but like all other succulent vegetable produce it should be given sparingly at first, and if in conjunction with other food like the grasses, saintfoin, &c., during the first few days of feeding so much the better; mustard being of a pungent nature, it is well calculated to assist in the digestion of other food. The analysis of the green plant will exhibit its nutritive value as a fodder plant, and also that it competes favourably with other green crops, including turnips, and is as follows :--

Nitrogenous compounds	
Vegetable fibre	4.39
Mineral matter	
•	200.00

As this crop is in perfection just before it comes into bloom it is desirable that it should be sown at different times, say once or twice a week, in order that it may be fed off in succession as it becomes fit and of most value, and in such acreage as the number of sheep will probably require. All green crops of this nature, particularly rape, are very likely to cause the sheep to become hoven or blown when first turned into a fold of it. Our plan to prevent this consists of letting the sheep feed twenty minutes then drive them off the fold for the same time, so that when they return to the food they may not overgorge themselves. From the time of sowing mustard will be fit for feeding at the end of about seven weeks, or six weeks if the land is in high condition or has received 1 cwt. of nitrate of soda per acre at seed time. This application frequently doubles the bulk of the crop. It is, how-

ever, in cultivation necessary that on the mixed soils the land should be fresh in chalk or lime, for we recollect once sowing mustard where the Swedes had died off with clubbed roots, that the mustard plants died off in precisely the same manner; not a single plant could be seen but suffered from clubbed root. With regard to the number of sheep which a good crop will feed, we have an illustration of it upon six acres of land sown with white mustard, four acres on the 10th of May and the remaining two acres on the 16th of May, and on the 21st of June the crop was 21 feet high, when it was commenced to feed 228 sheep and seventy lambs, which kept them twelve days in high and improving condition, being folded upon it at night, with only a bare lea field to exercise upon in the day.

The second part of our subject refers chiefly to the use of

mustard as a manurial crop ploughed-in green, and at the same time effecting all the objects of a fallow—that is, to grow three Crops in succ ssion of an overpowering bulk to keep down weeds, twitch, and black grass; and to illustrate the method of doing so we will state an actual experiment upon a field of stiff poor clay which was covered with twitch, that is water grass, or running grass, as it is sometimes called, not white-rooted couch. It was ploughed 7 inches deep in the winter, then scarified 3 inches deep the last week in March, and after being well harrowed sown with white mustard seed broadcast at the rate of 16 lbs. per acre, and covered-in by light harrowing. This crop was just breaking into bloom the last week in May, and 26 inches high, when it was ploughed-in about 4 inches deep, and one hundred bushels of lime (after been slaked with salt and water), applied per acre. Then after one turn of the heavy harrows it was resown with mustard, care being taken that all which was ploughed in within the day should be resown on the same day it was ploughed, all being finished on the lat of May. On the 8th day of July we began ploughing-in 6 inches deep this second crop, which was in height about 46 inches. As to accomplishing this we had some miscivings at first but managed it wall by attaching a heavy block givings at first, but managed it well by attaching a heavy block of wood 12 inches wide and 18 inches long drawn by a chain attached to the hinder bolt or whippletree, and dragged just under the plough beam a few inches in advance of the coulter. This further served to regulate the depth of furrow instead of the plough wheel. We had also the usual drag weight and chain to lap the whole under the furrow. About six furrows at the last must be done by the horses at length, or else the land horse re-turning on the same track as he went forward ricks and entangles the long stems so much together that they lap round the coulter and choke the plough. Immediately after the ploughing we gave one or two turns of the heavy iron harrows, then resowed the mustard as before, the whole field being done on the 12th of July. The third crop was just coming into bloom on the 24th of August, and the length of the stalks 4 feet. This was ploughedin 8 inches deep with four horses at length, followed by a two-ringed pressure. double pressure.

It is very important to consider in reference to the ploughing-in of mustard, or the making of a naked fallow, which plan is the least expensive; and if we reckon the number of ploughings, harrowings, rollings, &c., required in each case, we shall find the cultivation of mustard involves less labour than is required to keep the weeds and twitch down and cleared off the land in making the fallow, especially in a showery summer, because by the growth of mustard as above stated everything of the weed kind will be destroyed. In making a comparison of the advantages of feeding-off the mustard as against ploughing it in, we do not think there is much difference against that it is more difficult when the is much difference, except that it is more difficult when the requirements of the sheep are considered, to carry out the feeding and resowing with so much nicety as to time of feeding, &c., as in ploughing-down the crop. It is also worth consideration as to the effect of ploughing-in upon light soils compared with heavy land, for although the manure left in the land may be the same land, for although the manure left in the land may be the same land. in both cases, yet the mechanical action of the stalks and woody fibre which would in most cases be a disadvantage to loose soils, would prove a most important factor in ameliorating, lightening, and generally improving the working and cultivation of all clay

WORK ON THE HOME FARM.

Horse Labour.—This will still be required in harvest work in the late districts of the kingdom. At all other times when not so engaged the work attendant upon the wheat season will be necessary, such as laying-out the manure upon the clover leas, and ploughing and pressing the land immediately, for the longer the land lies before being sown or drilled with wheat the better, especially if the land is heavy loam or clay. It will now be none too soon to begin sowing wheat in the cold backward districts; 2 bushels of seed per acre will be sufficient at the first season, but later on 2½ bushels may be required, whilst at the latest season, say November, 3 bushels will be none too much. The home farmer must this autumn expect nearly all his crop on their first showing above ground to be attacked by slugs, and this will more especially be the case when wheat is sown out of lea. The young plants of trifolium also will probably suffer; and as the acreage of this crop is not usually large it may be worth while to take a

little extra care to prevent the slugs from eating it off. Lime is but little use, because a slight shower washes it off. The best plan is to carry a cartload or two of cabbage leaves or the leaves of turnips, Swedes, or any vegetable leaves, and spread over the field. The sluge are sure to take shelter under the leaves at night time, and early in the morning women or boys may pick off the slugs and carry them away, and pursue the same plan the following morning. This is the only effectual plan to destroy slugs, and in a crop of so much value as trifolium it may be made to answer a good purpose, and so it may upon les wheat if people can be found to do it, as it is only a question of labour. The outside and decaying yellow leaves of cabbages, &c., may be taken without injury to the crop for this purpose. Now the seed time has arrived it may be well to consider the varieties of wheat to be sown. The home farmer who has had experience will have noticed those varieties which suit the soil best under his management; but to those without much experience requiring seed wheat for cold and heavy loams we find the Golden Drop and Nursery, both red wheats, stand the winter well, even in elevated and exposed situations, and in case of loss of plant they are sure to tiller well and make up deficiencies. Upon light and friable soils in a mild climate, like most of the southern and eastern counties, we recommend Morton's Red Straw, Prince Albert, and the Essex Rough Chaff. These are all white wheats of good quality, but the latter variety is the best and most prolific upon land in the highest condition, as it is very short in the straw and scarcely ever becomes lodged or laid; at the same time it is one of the best grains for the miller. The season is now so far advanced that it is almost hopeless to expect to carry out autumn cleaning of the stubbles preparatory for roots next year, and in consequence all attention will be required to be given to sowing the rye, vetches, &c., and

Hand Labour .--The young plants of cabbage will now be strong enough to set out for an early crop in the spring. The remnants of the plants of Thousand-headed cabbage may be planted out in some fresh-ploughed stubble land to furnish food for sheep in the spring, for although these plants may be rough and long-stemmed they are sure to live if planted now, and will give abundance of spring food, and they may be ploughed-in at little expense, much less than by planting with the setting stick. The harvest being so late there will still be some ricks to be thatched and trimmed. The straw ricks also should be carefully thatched, and if the straw is required for feeding cattle the straw should be spiced whilst building the rick. This will be more particularly required if the straw is intended to be used for feeding sheep, as much of it this year will be no doubt, the hay having been got up so badly. The dairy cowe have done hadly lately where they have depended upon dairy cows have done badly lately where they have depended upon grass food only, for we know several dairies which for six weeks past have not furnished so much milk to be sent to London this past have not turnished so much misk to be sent to London this year by from 40 to 50 gallons per day as they did the year before, and it is just such seasons as this when it answers a good purpose to give the cows cake, maize, cracked beans, or millers' offal in addition to the grass they may get in the pastures. The time is now arrived, too, when we must expect the nights to be cold; and as the pastures will be wet lying for the weaned calves we recommend, therefore, that they should be taken to a dry paddock with hovel attached at night time, or else into a yard and dry shed, and receive some artificial food mixed with hay chaff. For very young calves at the time of weaning we must call attention to Bowick's "Farina," an article just coming into use, and highly recommended; "Farina," an article just coming into use, and nightly recommended, requires no boiling, is a perfect food for calves and young stock, and a complete substitute for milk. This is sold by T. Bowick and Co., Bedford. The price is 25s. per cwt., with full directions for use, and we say to the home farmer, Give it a trial. In buying in store cattle for winter feeding in yards or boxes we beg to suggest that it may be well to consider the policy of another plan, as our importations are likely to depress the value of fat beef. That is to buy in good shorthorned milch oows with calves at foot and give them the usual allowance of food for fattening an ox, keep them in the stalls in the same way, and sell milk or feed calves for veal as may be most convenient.

THE HEMEL HEMPSTEAD POULTRY SHOW.

THE second Hemel Hempstead Poultry Show took place on the 1st and 2nd inst. It was not so well favoured by the weather as lst and 2nd inst. It was not so well favoured by the weather as the first Show last year; still, in spite of heavy showers, it was well attended, and the whole neighbourhood seemed interested in the event. Not the least attraction was the great incubator tournament, on which we comment elsewhere. There were, too, many good and useful poultry appliances on view; travelling baskets, artificial mothers, Pigeon feeding boxes, &c. The local poultry and Pigeon classes occurring one immense marques, and poultry and Pigeon classes occupied one immense marquee, and attracted much attention. We thoroughly approve of this arrangement, and believe that if it were more thoroughly carried at all country shows something would really be done towards improving the breed of poultry in the country and encouraging its cultivation. Many of the local exhibits showed great merit. The finest bird in that section, which this year was confined to birds of the year was undoubtedly the Creve pullet to which the

five-guines cup was awarded. Brahmas, Dorkings, and Game Bantams were all good classes, and the Ducks magnificent, especially the first-prize Pekins. We do not like the system of cockerels and pullets competing singly against each other; it is almost impossible to compare their respective merits fairly, and a judge is much tempted to allot prizes alternately to the two sexes. When noticing the Hemel Hempstead schedule we attempted to describe the method to be pursued in allotting honorary prizes to the various sub-varieties in one class. As far as we could set it was not carried out by all the judges, and we doubt if it worked it was not carried out by all the judges, and we doubt if it worked well. The honorary prizes were not printed in the list, and consequently in some of the classes few pens seem to have been noticed, in which the Judge wished many to be distinguished by these honorary cards.

Dorkings came first in the open classes, and a noble Dark cockerel indeed was first on the list. He had come all the way from Ireland, and had borne his journey well. Second another

good bird; his equal in points, though not in size. There were many fine pullets among the Darks, but nearly all too dark in feet. A beautiful silvery cockerel was first in the Any other variety Dorking class, and a forward White second.

Cochins were not strikingly good. The first Buff, a pullet, was admirable in shape; and the second, a cockerel, handsome too. Partridge were better than White. First a cockerel, and second a well-pencilled pullet.

Brahmas were far better than the Coching. In Lights first and

Brahmas were far better than the Cochins. In Lights first and econd were two fine cockerels, the first magnificent in shape. Darks pullets carried off the palm. First a grand bird in form, and beautiful in pencilling.

Game made small classes. The Piles were much better than the Reds. The first Pile cockerel was extremely forward and good.

Hamburghs two fair classes. In that for Golden of both kinds

mamburghs two fair classes. In that for Golden of both kinds nearly every pen was up to a good average. A pencilled cockerel was first, a pullet ditto second, and a spangled pullet third. The Silver class was small. All the prizes went to Spangles. There certainly is a great opening in the south of England for Silver-pencils. We were glad to learn from the Judge of these classes (Mr. O. E. Cresswell) that he considered them very honestly shown. It certainly is something to hear of two classes of Hamburghs all with natural combs.

Polands.—As usual in these days Silvers were ahead. First a beautiful pullet, second a fine cockerel; a Golden pullet came in third. Two White-crested Black cockerels were shown, but were better in crest than carriage. Several Padua Chamois put in an appearance, but the best unfortunately were sent in pairs instead

of singly.

Spanish were not remarkable beyond the first-prize cockerel, which had a face of beautiful texture.

Houdans.—The cockerels of this breed seem deteriorating. We saw no good one in the Show. First and second were really fine

Crève-Cœurs.—Some fine and massive birds were shown. The first

cockerel was specially good, and a fine and cheap pullet second.

Leghorns were one of the best classes. Their admirers are to be congratulated on the great improvement now to be seen in both varieties. A White cockerel was first, a Brown pullet second, and a White pullet third; all super-excellent birds.

a White pullet third; all super-excellent birds.

Andalusians, too, made a good class. The first cockerel was easily shead; second a pullet, too dark in hackle to please some fanciers; third a younger but very fine cockerel.

Any other Variety was a remarkable class for its size. The Judge awarded five instead of three prizes, as he was empowered to do by the rules. First was a beautiful Black Minorca cockerel, equal accord were a nice Black Hamburgh cockerel and a Le Whole

by the rules. First was a beautiful Black Minorca cockerel, equal second were a nice Black Hamburgh cockerel and a La Flèche cockerel, equal third a Black Hamburgh pullet and a Malay pullet. Bantams.—The Game Bantams were only fair. The first Black Reds were slim and good in style. In the Variety class Golden Sebrights were first, nicely marked, but too large, as nearly all Sebrights are now-a-days; nice Black Rose-combed were second, and Silver Sebrights third.

Ducks.—The first prize in the class for the larger varieties of Ducks was first awarded to a grand pair of Rouens; the drake certainly had a very suspicious look about his wings. A protest was lodged against the award and was sustained. The first prize then went to a grand pair of Aylesburys; second to Pekins; and third to Aylesburys. The Variety Duck class contained nothing very new, though the birds shown in it were chiefly in nice condition. Spotted-billed Ducks came in first, Carolinas second, and Whistlers third.

lers third.

Pigeons.—Considering the time of year the show of Pigeons was good, though the great feature of the Show is the poultry. A grand Black Carrier was passed by, we suppose because the Judge thought him not honestly shown. The first Dun Carrier was a noble bird with beautiful beak wattle. In Pouters a capital White came in first; Short-faced Tumblers were good, the winners all Almonds. Barbs were few but good. Two good Yellow Jacobins came in first and second, well ahead of the rest. Fantails neither deserved or received any prizes. Turbits were about the best class; the first Blue and second Red, such birds as might win anywhere. We rather preferred the second Blue Dragoon to its owner's

first-prize bird. The Variety class was small and contained nothing

remarkable.

The Judges were as follows:—In the open poultry classes Mr. O. E. Cresswell judged the Dorkings, Cochins, Hamburghs, Polish, and Any other Variety; Mr. S. Matthews the Game and Game Bantams; and Mr. Leno the remainder. Mr. Esquilant took all the open classes of Pigeons. The local poultry classes were judged by Mr. T. C. Burnell, Rev. G. Raynor, and Mr. W. B. Tegetmeier. Mr. T. Burnell and Mr. Tegetmeier judged the local Pigeons.

THE INCUBATOR CONTEST AT HEMEL HEMPSTEAD.

WE give elsewhere the result of the second great contest of incubators at Hemel Hempstead. It is about a year and a half since the promoters of this Show announced that in connection with their show of poultry in the autumn of 1878 a grand contest of incubators would be held. The resolve was a most patriotic one, intended to prove in the first instance for the benefit of the people of Hertfordshire, and secondly for that of poultry breeders in general, if there were any incubator which could really be trusted to without any excessive amount of care to do the work of hens, and if so which of the many machines was the most reliable and most easily managed. The prize offered for the best (£25) was such as could not fail to secure the entry of any incubator worthy such as could not fail to secure the entry of any inclustor worthy of notice. From time to time there has been considerable but fitful interest excited in artificial incubation. We can remember several incubators being brought out about twelve years ago; we tried two, but after infinite pains and trouble taken found the result most unsatisfactory, and we believe that nearly everyone gave them up, as we did ourselves, in disgust. The fact, however, remained indisputable, though not well known, that at various times, some very remote, and in many countries artificial incubation had been successfully carried-on on a large scale, and that at this day the Chinese carry it on. Some time ago we translated several chapters of Reaumur's old book on the subject, in which he relates various experiments, some of which ended in success, made under very various circumstances in France. If in such primitive days care and observation could overcome all difficulties connected with the out when it than the content of the content with the art, why in these times of scientific progress should they not be easily surmounted? The question probably occurred to many, and hence several fresh inventions in the way of incubators came out, and were quickly followed by a new revival of interest in the subject.

This great contest was arranged most opportunely, and was, as we believe, most admirably and fairly carried out. Our readers probably remember its conditions and method; each exhibitor of an incubator had to send his machine with full directions for its an incubator had to send his machine with full directions for its management. They were placed under the care of an impartial and intelligent person in a building to which some of the managing committee alone had access, and the incubator which in twenty-one days precisely hatched out the greatest per-centage of chickens from the fertile eggs in it was the winner. The prize was awarded to Christy's, which was far ahead of the other competing machines. This incubator is on an entirely different principle to all those generally known before. How far it is an original invention we do not pretend to say, for there are French incubators on the same principle. Its peculiarity is that no lamp is required for it at all; it is heated by hot water, and twice a day a certain amount of water is drawn off from its cistern, and a certain amount of water is drawn off from its cistern, and a certain amount of boiling water added. The method seems a simple one and commendable. Unfortunately the unsuccessful exhibitors did not bear their defeat so philosophically or so good-humouredly as could have been hoped. They grumbled at the way in which the contest had been arranged—viz., at the management of the incucontest had been arranged—viz., at the management of the incu-bators by one impartial person, and consider that they ought each to have superintended their own. One indeed, or rather we believe to have superintended their own. One indeed, or rather we believe this agent, went so far as to impute partiality if not dishonesty to the manager of the contest and to some of the chief promoters of the Show. The mode of competition had been carefully arranged after much consultation, and the result had not been doubtful; so for our own part we should have been inclined to rest content with its results, and leave the grumbling exhibitors to improve their imperfect machines to their own perfect satisfaction, if not to that of the public Margara the accornic model of Hamel to that of the public. However, the energetic people of Hemel Hempstead decided to give them another chance, and offered another prize, this time £10, for the best incubator. The method of contest was this year varied; each exhibitor was allowed to manage his own incubator in accordance with the wishes of the majority who competed last year. The keys of the building in which the contest was held were given to one responsible person, and the various exhibitors were admitted at stated times to attend to their incubators.

The result which we give elsewhere shows two facts:—1st, That under these altered conditions of competition one of Christy's incubators again has won the first prize. 2nd, That there is a great general improvement in the average number of chickens hatched from the machines collectively, one of which alone failed altogether from some difficulty with the management of the gas.

This result seems to us very satisfactory, for the obvious conclusion from it is that there is one incubator in which considerable reliance can be placed, for we understand that it was managed by a local person who knew nothing of incubators before, and not by any expert specially sent down, and also that there are several others which are in a fair way to be made practically useful, though at present their working is not so simple or their results quite so startling.

We regret to learn that the unsuccessful exhibitors again refuse to take defeat gracefully, and soon after the termination of the contest addressed something like a collective protest against its management to the authorities; one even went so far as to make grave imputations against some person or persons whom he did not name. We trust that ere this the excitement of the moment may have calmed down, and that the protestors in a calmer frame of mind may have withdrawn their objections. The Committee of the Hemel Hempstead Show have been most spirited and most public-spirited in originating and in twice carrying out so interesting an experiment. They have quite effected their object, and consequently, we believe, there is little chance of another contest taking place. That a wide circle of poultry fanciers and Game breeders is heartily obliged to them for what they have done we have much reason to know.--C.

VARIETIES.

THE Dairy Show, which will take place in the third week of this month in London, will be attended in a prominent manner by German dairy producers. The "Milchwirthschaftliche Verein" has taken the management in hand—about 140 entries in the classes of butter and cheese have been made. In latter years in Germany very much has been done for the development of the dairy and improvement in the butter and cheese making, and the coming show will be an occasion to make ourselves acquainted with the results obtained.

MR. H. M. JENKINS, Secretary of the Royal Agricultural Society of England, has been appointed Assistant Commissioner in charge of the reports to be made upon European agriculture. He will be assisted in the necessary investigation. He will be assisted in the necessary investigations by Mr. C. L. Sutherland of Coombe, Croydon. Mr. Jenkins has already commenced his inquiries in Holland, and Mr. Sutherland has started for Paris, with a view to inquire into the corn-growing districts of France.

THE second great contest of incubators held at Hemel Hempstead was brought to a close at noon on Wednesday, October 1st, when the first prize was again awarded to one of Christy's incubators. The analysis of the working of the various incubators is as follows :-

	No. of eggs originally placed in incubator.	No. found unfertile on sixth day.	No. found fertile.	Number hatched out.	No. found in drawers unhatched at noon October 1.	Percent'ge hatched.
T. Christy & Co. No. 2. C. Cashmore No. 2. F. Howell No. 1. T. Christy & Co. No. 1. F. Howell No. 2. Watson. C. Cashmore No. 1.	80 50 100 100 60 60	9 8 83 10 7 6	71 42 67 90 58 54 Fai	69 94 88 89 90 11	2 18 29 51 83 48	97,18 57,14 56,71 43,33 87,73 20,37

THE Prairie Farmer states, that for the week ending August 80th, there were shipped from Atlantic ports 4,500,000 bushels of wheat. For the six weeks ending August 80th, the exports of wheat exceeded those for a corresponding period last year by 9,970,000 bushels.

— WE regret to have to record the death of another poultry factor. Dr. Etheridge of Bromyard, which took place somewhat addenly on Friday evening 26th ult. Dr. Etheridge was well hown as a fancier of Game, and some of his chickens, which were setually at the time of his death at the Worcester Show, were very temarkable and promising.

A REPORT from New York published in the Toronto Mail States that the export of dressed meat to the English market, which reached large proportions two years ago, but was temporarily eached large proportions two years ago, but was temporarily suspended in consequence of the increasing shipments of live Cattle, is about to be revived on an extended scale. The action recently taken by the British Government to check the exportation of cattle from this country has produced its natural effect. Large dealers in cattle and beef have given up exporting live cattle and again turned their attention to the export trade in dressed beef, and a new system of refrigerating is being put into action, whereby the necessity of using ice on board the steamships will be done away with. It has been found through numerons trials in done away with. It has been found, through numerous trials in exporting meats, that they must not be frozen, but only kept at a temperature which will delay decomposition. The new system is said to be perfection. The cooling process is produced by means of compressed air, which can, if necessary, be reduced in temperature even below zero. It is expected the fresh meat trade to Great Britain can be revived to its former magnitude, and even exceed it.

THE TREATMENT OF FOUL BROOD.

(Continued from page 282.)

THE great importance of the question of foul brood and the urgency with which remedies are called for has been evidenced by the number of letters I have received since I have addressed myself to its consideration in the columns of this Journal. After giving, by Mr. Cowan's kind permission, his plan of operations I promised to say something of the method I had adopted, and by which success of a very marked kind had been obtained; but before entering upon this it may be interesting to speculate as to the reason salicylic acid effects a cure, and as to how far it may be employed to ward off a chance attack without injury to the bees. Salicylic acid has been found to act upon the human sysbees. Salicylic acid has been found to act upon the human sys-tem as a retarder of oxidation; in simple words it reduces the rate at which waste goes on in the body, but as a natural conse-quence it lowers vital action and interferes with the production of animal heat. Carbonic acid is given off in reduced amount by or animal heat. Caroonic acid is given on in reduced amount by an animal to whom a large dose of salicylic acid has been administered. Now it is well known that the growth of fungi is always attended with the production of carbonic acid, so it is perhaps probable that salicylic acid is a fungicide, as Cork calls it, or an enemy to fungoid life, because it arrests that very process which is a vital action of the fungus. If this be true, or even if it be not, we now see that perhaps some disadvantage may arise from an excessive use of the remedy. I note this because I am glad to be able to testify to feeding continually, with no observable bad effect, with food containing four or five times as much acid as Mr. Cowan recommends; and as his strength was curative, of which we have his evidence, we see that it is safe to use even more of the remedy than is demanded by the disease use even more of the remedy than is demanded by the disease without appreciable injury to the patients. Mr. Cowan's mixture (see last issue) for spraying combs and painting hives is about one-eightleth part by weight salicylic acid; while Mr. Hilbert effected an absolute cure by spraying with a mixture containing one part of the remedy in 160 water; and Muth, who first suggested borax for the purpose of rendering salicylic acid more soluble, used a mixture consisting of one of the latter diffused in sixty of water.

In treating an infected hive it should be remembered that cutting out the combs dotted with dead grubs and then allowing the bees to build again not only does not remove the infection but it weakens the stock. This plan, which is the one expedient of some who should know better, is about as intelligent as would be cutting off a man's leg to cure him of scarlet fever. The honey left to the bees has been dusted by the spores before it was sealed, to the bees has been dusted by the spores before it was sealed, and there these remain to be given in the pap the nurses are always dispensing to the wanting babies. The disease is thus left to establish itself anew, giving more work to the exciser of combs, till the poor colony dies of disease and the doctor. When combs are in a very decomposed condition they may have to be taken away; but I do not believe, rather I have not found, this step to be generally necessary. It is in my opinion far more necessary to remove the store; for, supposing the honey to carry no infection, it is at least the means of preventing our remedy being given to the grabs. Remove the store and feed with syrup containing salicylic acid, and the bees themselves in nonrishing their progeny salicylic acid, and the bees themselves in nourishing their progeny sancync acid, and the bees themselves in nourishing their progeny become the dispensers of the drugs we have provided. While this feeding is going forward we periodically, about every three days at first, inspect the hive, and lifting out the combs singly, we open with a penknife all cells supposed to be diseased. The spray-producer is then called into play, and the fluid for this spray I always use as hot as possible, for if it were boi ing in the vessel it comes out in so fine a rain that evaporation immediately cools

it completely.

The apparatus which has carried me through all the treatment necessary for many cures is Maw's shilling scent-diffuser, consisting of an indiarubber ball, a small bottle with screw neck, and the necessary tube adjustment. The bees are childed and tightly grip the comb, but they quickly recover when the hive is shut. The next inspection sees the before-explained process repeated; other cells are opened, all are sprayed, and thus in a few times no cell in the hive but has received some of our fungicide and the disease succumbs. In milder cases no more than this will be needed, but in neglected ones the worst broodcombs had better be replaced and the hive changed, the old one being thoroughly washed with strong salicylicated solution. The idea that the queen should be serving sancymeated solution. The idea that the queen should be removed to stop the production of brood and give the bees time to clean the combs is not, now at least, to be entertained. Where foul brood exists in any hive in the apiary none are safe, and most are in all probability already tainted, so that feeding with salicylicated syrup is at all times desirable. My practice, as I stated reservoirs has been the size observed by the salicylicated syrup is at all times desirable. stated previously, has been to give about thirty grains—a small teaspoonful—of acid with each 14 lbs. of sugar made into syrup, Mr. Cowan using only eight grains for the same amount; and from my larger quantity no bad symptoms have arisen, while no trace of foul b ood has appeared in any hive for two seasons

The Rev. G. Raynor lately informed me that he thus always added salicylic acid to all food given in his apiary, and that he has had perfect immunity from any attack. This medicated syrup is simply made by adding to the sugar and water as it is heating on the fire the required quantity of salicylic acid, to which previously about a quarter of its weight of powdered borax has been added.

America with its large apiaries would have suffered awfully from the ravages of this enemy had it not been for treatment, but the intelligent apiarians of that country have so well fought the disease that it is disappearing from amongst them. So let it be with us. Our neighbours the Germans have found us a remedy; let us use it and spread its fame abroad until foul brood shall become a curiosity. - FRANK B. CHESHIRE, Avenue House, Acton.

HEMEL HEMPSTEAD BEE SHOW.

OF the county associations none are stronger than that of Hertfordshire, although it was called into existence last year only. The wonderful energy and self-sacrifice of its Hon. Sec., the Rev. Herbert Peel, is no doubt in large part the reason of its rapid growth, enabling it thus early to organise and successfully carry through such an exhibition as it held in the Bury Grounds, Hemel

Hempstead, October 1st and 2nd.

The schedule comprised fifteen classes, which were generally well filled; and indeed in honey the number and quality of the English exhibits were the best this year of disappointment produced. It was highly gratifying to those who are at so much pains to spread a better knowledge of rational bee culture to find pains to spreak a better knowledge of rational best duture to find no less than nine men of the county entering the competition in best-driving—i.e., if one may be reckoned as a man whose age appeared to be about thirteen. So creditably, too, did these acquit themselves that the winner ran neck and neck with the acquit themselves that the winner ran neck and neck with the best in a similar competition open to all England. The Rev. G. Raynor, and Messrs. Cowan, Cheshire, Tegetmeier, and Martin acted as Judges, and appeared to give general satisfaction. Bees call for no special remark, except that Mr. Abboti's Ligurians were well marked and Messrs. Neighbours' Hungarians distinct. In Class 3, for the most complete hive on moveable-comb principles, there were twelve entries. Messrs. Hooker and Abbott were placed first and sesond as at Kensington and for the hives then shown, and which were then described in these columns. The crates of and which were then described in these columns. The crates of sections of both have been slightly improved, Mr. Hooker's being to our mind the most convenient of any yet seen. Mr. Abbott has not yet added separators, without which sections cannot be used to advantage, since their combs will never be straight enough to admit of glazing. Mr. Clapp takes third honours with a good hive. Mr. Picton and Mr. Franklin appear as local recruits to the ranks of hive-makers. The exhibit of the first is well made; that of the second is too fanciful to be useful, while its stand is far too small for safety. Class 4, cottagers' bar-frame hive, price limited to 10s.—Mr. Fuggle again first with splendid value for money. Mr. Baldwin second, and Mesers. Abbott third, the exhibit of the latter being weakest in its sections, which are rickety and would plague the most skilful operator. In Class 5, straw hive with moveable combs, Mr. Neighbour first. We preferred Mr. Abbott's,

but this did not conform accurately to the schedule. Class 6, section crates. Mr. Steel first with a crate with tightening slides and separators, an arrangement good and cheap, but ening shoes and separators, an arrangement good and clearly out not equal to parallel wedges, which strangely no one shows except Mr. Hooker. Second, Messrs. Neighbour with queen-excluder and separators. Mr. Abbott third with sections, cheap, but again

without separators.

In Class 7, extractor, Mr. Watson won with a good useful machine now well known, "The Little Wonder" coming second, while third place is given to an evident copy of No. 2. Mr. Steele exhibits, but his extractor has been made in ignorance of the laws of centrifugal force, which the Judges in this class (Mr. T. W. Cowan was of the number) as scientific men spotted of course, and justly left the extractor out of the competition.

and justly left the extractor out of the competition.

In sections of honey many fell behind, not because the year has been bad, but because they have not yet learned the art of section-producing. Clearly the separator is as yet unknown in more apiaries than one from which sections went to Hemel Hempstead. In the All-comers' class Mr. Cheshire stood first with sections of great beauty. Class 9, Hertfordshire section, Mr. S. Thorne first and second, Miss Gayton third; Rev. H. W. Hodgson and E. Gulston highly commended. Class 10, single sections, S. Thorne first and second, Miss Gayton third; G. Freeman and E. Gulston highly commended. Class 11, extracted honey, Mr. S. Thorne first, Mr. Cheshire second. Class 11, extracted honey, Mr. S. Thorne first, Mr. J. Clapp second. This honey was in great quantity but of bad colour, probably through the prevalence of the sycamore aphis. Class 12, comb honey, Mr. S. Thorne, Mr. Clay, and Mr. Loyd first, second, and third.

The driving competition amongst the local bee-keepers was

The driving competition amongst the local bee-keepers was most interesting; and as some of the competitors were quite of the cottager class, shows that centres of influence are multiplying which must at length abolish the sulphur pit and establish a

better system.

In the open competition Mr. Walton completed driving and transferring in ten minutes and a half, and so won, Messrs. Baldwin and J. Abbott following second and third; while Messrs. C. N. Abbott and Martin had the fates against them, as both were

C. N. Abbott and martin had the rates against them, as both were out of it through missing their queens.

The Rev. E. Bartrum kindly lectured during part of the afternoon of Wednesday to the assembled spectators, Mr. Cheshire doing the same on Thursday. The Hon. Scoretary had, as is his wont, arranged all prize moneys before the close of the exhibition, and these were distributed to the successful by the Countess Grimstone in the Committee tent in the presence of the assembled visitors, whose hearty cheering of the Countess and the esteemed Hon. Secretary brought the first Hertfordshire Exhibition to a termination.

OUR LETTER BOX.

WILD FOWLS (Novice) .-- They are Teal, probably.

While Fuwis (Novice).—They are Teal, proceedly.

CHEAPEST FOOD (M. M.).—The best and cheapest artificial food for bees is made from sugar and water boiled together at the rate of 1 h. of segar with one pint of water. Let the syrup boil for half a minute. Antenna feeding should be done rapidly—that is to say, as fast as the bees will take the syrup from the feeders. Slow continuous feeding is not desirable now, for it may cause the bees to fly too much abroad, and also to bread at an improper season. The quieter bees of strong stocks sit during the months of October, November, December, and January the better. Let your bees have enough now to last them till March.

have enough now to last them till March.

BROWN COMES, &C. (Busy).—The brown combs you speak of would be a greater hindrance than a help to a swarm next year. They are weens than useless for future use. Boil them down for wax. Any respectable iron-monger would supply you with a spring steelyard to weigh hives or anything up to 70 fbs. If your bees have not enough to keep them alive till March give them more: 13 or 14 fbs. of honey or syrup stored up would serve an ordinary strong hive in an ordinary season from the beginning of October till the end of March. Very large stooks well peopled have been known to eat \$4 fbs. and \$5 fbs. each during the autumn and winter months. In hard winters less food is consumed than in warm ones. By using the smoke of corduroy you will soon become expert and courageous in examining your hives. vour hives.

QUEEN FLYING (T. F., Cold Harbour).—Laying queens never, at least we have known of two exceptions only, fly from their combs when their hive is opened; but queens that have had a long journey, like the Italian methers, are disposed to fly when the boxes in which they have been packed are opened. If they do so let the box remain, and they will in a few minutes return to it. return to it.

REMARKS.

Damp and drizzling in first part of morning; rather windy in the middle of the day, with just a glimpee of susshine afterwards, one or two slight showers; fine afternoon and evening.

—Fine day throughout, with one or two sudden showers in the morning.

3rd.—Rather cold, but on the whole a fine day, though at times cloudy.
4th.—Fine bright day, and a good deal warmer; a little cloudy in afternoon;

misty evening.

5th.—A dull and oppressive day, though fair.
6th.—Fine bright day.
7th.—A little dull in first part of morning, afterwards fine and bright.

7th.—A little dull in first part of morning, arterwards one and origint.
The weather on the whole has been very fine and pleasant, though some days were rather cold. The mean of the barometer readings is high and somewhat above that of last week; in fact, it has been higher each week since the beginning of September. The mean temperatures show very little variation from those of last week.—G. J. SYMONS.

COVENT GARDEN MARKET .-- OCTOBER 8. TRADE has been quiet with us the last few days, and prices have generally received a check. FRUIT.

From observations taken near London during forty-three years, the average day temperature of the week is 59.1°; and its night mperature 40.6°.

CULTIVATION OF THE MELON.

OR many years I have practised with success a mode of growing Melons different from that recommended by some of the leading horticultural writers. I have been asked by some of the readers of the Journal of Horticulture to describe my system and its results. Though reluctant to enter the field

as a writer on a matter that has been so largely discussed, I have thought that it can do no harm

only to state my own experience.

Perhaps the principal feature of my system is in supplying the plants liberally with water at all stages of their growth, so as to keep them in perfect health and in a bearing state as long as possible; whereas the generality of writers recommend the withholding of water at the root and keeping a drier atmosphere as the fruit approaches maturity. By following the latter mode of culture the plants are stopped in their growth, wither up, and some even die before the first crop of fruit is ripe, and if they do not die they are worthless for further cropping. This drying-off system is practised with the idea that it imparts a superior flavour to the fruit. But taking a natural view of the subject, I cannot see how plants in a dying state can yield as good a flavour, or finish off the fruit to anything like the same perfection, as plants in a robust state of health.

It is long since I made up my mind that the drying-off system was a mistake, and the last eighteen years' experience has proved to my satisfaction I was correct in thinking so. I never allow the plants to suffer for want of water at any time, nor withhold syringing, no matter what state of ripeness the fruit is in, and I have seldom had cracked or a badly flavoured fruit. With plants grown in a house, and trained on a trellis and treated liberally, I have no difficulty in obtaining fruit for a long season in succession in the same way and with no more trouble than with Cucumbers. As the plants grow older they produce fruit more freely, and I find no difficulty in inducing the fruits to set and swell off. They set so freely that I have generally to thin them out, and it is seldom that there are less than from six to eight fruits on a plant all in different stages of growth at the same time. It is different when the plants are young and vigorous. Many of the first fruits after they set turn yellow and die, but after the first five or six have swelled off (if the plants are kept clean and healthy) they will then set and swell off as freely as Cucumbers, and bear fine fruit for a long time if properly attended to.

My experience is different with Melons grown in hotbeds. pites, and cold frames, and I cannot say the same of their bearing qualities, more especially when the vines are trained on the soil in which they are planted. For one thing, there is more difficulty in working amongst them; the lights have to be taken off every time attention is necessary, such as watering, syringing, and stopping shoots, which must be done when the weather is favourable; and in cold wet seasons like the present the stems are liable to decay when lying on

advantage of the plants being always under one's eye and easily attended to as regards stopping and regulating the shoots, fertilising the fruit, watering the borders, syringing, &c., at all times and in all kinds of weather.

Some cultivators rely more on the soil in which Melons are grown than they do on the general treatment of the plants. I feel certain that Melons can be grown, and grown well, in almost any kind of garden soil, if they receive a liberal supply of liquid manure and are otherwise properly attended to during the season. I have frequently grown Melons for two years in the same soil, and the produce of both years has been first-prize fruit at exhibition tables where there was great competition. I mention this to show that more depends on the general treatment than on any particular kind of soil producing good fruit. The soil here is a brown loam, which is apt to run together and crack when used by itself. To prevent it from cracking and make it porous I add one barrowful of decayed horse droppings and a little charcoal to every three barrowfuls of soil. After all has been thoroughly mixed together by frequent turnings it is trodden firmly and evenly in the bed where the Melons are to be grown.

Everyone who has had much experience in growing Melons knows how apt the plants are to decay close at the neck of the stem if the soil is at all damp, and how provoking it is to see the plants in a whole frame ruined before a fruit has been gathered. With the idea of protecting the necks of the plants and preventing decay I had collars made of the same material as flower pots, 10 inches in diameter, 2 inches deep, and 1 inch thick, to guard off water when watering the borders. The soil is raised a little higher than the rest of the bed, so as to allow of heavy waterings without the water coming in contact with the stems of the plants. After the plants have been planted and watered a first time the collars are placed over them and pressed firmly down on the soil, so that the bed can be freely watered when required without the water touching the stems of the plants, as the spaces inside the collars are never watered afterwards. In a short time the soil becomes as dry as powder, and I have never known a plant to rot at

the neck since I adopted this plan.

The plants are allowed to grow to within 18 inches of the top of the trellis (which is some 7 feet) before they are stopped and all the tendrils are taken off as they appear. The lateral shoots are stopped at the first leaf above the fruit, and the first female flower that appears is fertilised, and others as they appear are operated on in succession. When there are too many sets at first they are thinned out to five or six, and by the time that they have reached maturity there is no difficulty afterwards in keeping up a succession of fruit for months. The beds are watered regularly with liquid manure when required, and the surface of the bed is damped over, and the plants syringed every morning and evening to keep down red spider and encourage a robust growth, as previously stated, no matter what state of ripeness the fruit is in. I am still cutting good fruits from plants planted in a house in the beginning of April, which have been bearing heavily all summer. While I write (September the ground. With Melons grown in a house there is the 22nd) six plants are ripening five fruits each in different

NO. 1620.-VOL. LXIL, OLD SERIES.

NO. 968.-VOL. XXXVII., NEW SERIES.

stages of maturity; while those which were much later planted in pots and frames are all gone some time since.—A. PETTI-GREW, Castle Gardens, Cardiff.

A PEEP AT THE PERENNIALS.

OUR perennials, being specially selected for late blooming, have not yet lost much in beauty, although October is come; there are, indeed, many of the best things only just peeping A few I fear, as Aster out, and some have not shown colour. grandiflora, Schizostylis coccinea, and Stokesia cyanea, will be too late in this backward season to unfold their blooms at all. Colchicums are coming up fast. The Double White (C. autumnale album plenum) is especially beautiful, as spotless as a Tuberose and almost equal to it for a bridal bouquet; indeed for those who do not like the somewhat heavy scent of the Tuberose this Double White Meadow Saffron would be pre-ferable. Next in beauty, according to my estimation, is C. by-zantinum, a single rose-coloured flower; and then C. speciosum, a larger, newer, and rarer kind, of great beauty. have also other single kinds, as C. autumnale variegatum, the flowers of which are beautifully spotted regularly all over with white; and C. autumnale striatum, irregularly striped, not so pretty as variegatum; and the double rose-coloured C. autumnale plenum. Autumn Crocuses are exceedingly pretty, and there are some beautiful colours among them which are not to be found in the Colchicums; but they have this disadvantage—the rats and mice greedily devour the bulbs, while they know better than to touch the Colchicums. I know there are traps and poisons for rats, but unfortunately pheasants, too, are liable to be trapped and poisoned, and killing a pheasant is in some places I could name a greater crime than being without a Crocus. Œnothera Youngii is a little past its best, but still very beautiful; it grows about 18 inches high, and has bright yellow flowers much in the way of Œ. Fraseri, but the foliage and habit of the plant have a lighter appearance than the last-named, and I prefer it to E. Fraseri. Last-autumn self-sown seedlings of both sorts are coming into flower, and I think it very probable they would make good bedding plants if treated as biennials. The Japan Anemones (hybrida japonica and Honorine Jobert) are of course in their best array, and unlike many of the herbaceous plants they look well in any position. In round beds about 4 feet across they are especially handsome, and for cutting are invaluable.

The scarlet Monarda (M. didyma) is over, but M. mollis, a lilac-coloured species of good habit, is just in its beauty; and M. purpurea is still in flower. The Monardas all have a pleasant aromatic scent, and are (perhaps locally) known by the name of Bergamot. Sedum Fabaria is another well-known plant that will do in any position, excepting perhaps in very large masses, when I think it looks heavy. S. Fabaria album is a mismomer, having greenish flowers of no beauty. The season for S. Warcsewiczii, a yellow species, is over; but self-sown seedlings are now in full flower and are pretty. Œnothers riparis, of trailing labit, covers good patches near the edge with its bright yellow flowers; and Œ speciosa is a particularly handsome plant, from 18 inches to 2 feet high, with flowers nearly as large as CE. macrocarpa, having yellow centre and veins on pure white ground, which afterwards changes to pink. Polygonum Brunonis is a trailing plant with beautiful pink spikes of flowers; and P. viviparum is interesting from bearing living plants on the flower stems. P. Sieboldii, on the other hand, is a giant, and should not be in the perennial border proper; it looks well on the grass by itself or in an open space between large shrubs; it is a strictly herbaceous plant, grows 8 or 10 feet high and as much through. Another giant herbaceous plant is a variety of Eupatorium purpureum, which grows 11 or 12 feet high every season and has a majestic appearance. Arundo Donax grows nearly as high; it ought perhaps not to be in the herbaceous border, but it looks well anywhere, and especially so when near water. The variegated variety I am happy to say withstood the ordeal of last winter without protection. It is planted in peaty soil near Rhododendrons, the roots of which no doubt tend to keep the soil dry and sweet. The ordinary Tiger Lily is over, but Fortune's variety is now in bloom, and is at least equal to the older one. Lilium auratum varies a good deal in its season of flowering, as well as colour. One plant, which has been out five years and has a spike 7 feet high, is only just expanding its first blooms, which are of a very large size. Another, planted about the same time, flowered in August, and was equally as large and good. They like peaty soil and dislike to be dis-

turbed; while as to hardihood, a young bulb formed on the top of an old one was lying uncovered all last winter and is now growing freely. Coreopsis przecox, 4 feet high, bright yellow in colour, is very showy, is good for cutting, and takes care of itself, excepting as regards snails. Of Tradescantia virginica there are several varieties shading from blue and purple to

pink; I believe I have seen a white one, but I do not possess it. Eryngiums, blue Teasle-like plants, are all exceedingly beautiful, especially E. amethystinum. Centrocarpha grandiflora (or Rudbeckia) is 2½ feet high and as much through; has large yellow flowers with black centres, some of which are close to the ground. This plant is more vigorous than most of the Rudbeckias; it wants a good space to develope itself, and a position where it can be seen at least three parts of the way round. Funkias all have beautiful foliage. F. Sieboldii variette in good draws one with ground and white strick least three parts. gata is a good dwarf one with green and white stripes, almost equal to an Aspidistra, and F. grandiflora has large bluish flowers. Cassia marylandica is a tallish plant with handsome leaves and bright yellow flowers. Crucianella stylosa is a pink trailer which smells like a fox. Lobelia syphilitica in variety is handsome, and would probably take care of itself at the margin of a shrubbery, as its self-sown seedlings are now flowering in company with the parent plants. Hyacinthus candicans I will not attempt to describe, it wants a poet to do that; it has been flowering for two months, and looks likely to continue as long as the weather permits. This was not planted out till spring this year, so I cannot of my own experience warrant it to stand the severest winters, but I hear it has done so in some places. As a precaution I shall cover one of my plants with ashes, and let the other take its chance. Euphorbia myrsinites is a dwarf spreading plant out of flower now, but its evergreen glaucous foliage is always handsome. Statice latifolia with beautiful large leaves and lavender-coloured flowers is now in full beauty, and so is S. spathulata, a miniature variety (or species). Amongst the Michaelmas Daisies are a great many weeds in botanical collections, but those I shall name are something very different to weeds. Aster pendula I think is as handsome as any I know, it is 3 feet high and nearly blue.

A. Amellus, A. amelloides, and A. Amellus bessarabicus are a good deal alike, but vary in their time of flowering, and in their shades of purple, as well as having more or less yellow in the centre of the flower. They are all three about 18 inches high. A. longifolius formosus is fast expanding its bright pink flowers in great abundance; this is also about 18 inches high and is extremely beautiful, but unfortunately the slugs are very fond of its young shoots in spring. A. ericoides is a graceful plant with numerous pretty small white flowers; it grows 3 feet or more in height. Harrison's Musk is still in flower; I should be glad to hear the experience of those who have tried this plant for bedding, as we are short of a dwarf yellow plant for this purpose. Phygelius capensis is not flowering as well as usual this year, it having been cut down close to the ground by the frost; its scarlet spikes of flowers are ever welcome. Among other good things in flower now are the Solidagos, Tritomas, Aconitum autumnale, Physostegia speciosa, Achillea Ageratum, Veronica virginica, Helianthus multiflorus, Pyrethrum uliginosum, Sylphium trifoliatum, &c. Lilium speciosum and its varieties are not in flower yet, but they look very healthy. WILLIAM TAYLOR.

HYDRANGEAS.

PINK and blue flowers on one Hydrangea plant, of which "J. W., Kent," sent you an instance of a week or two ago, is not unusual here. Many of the plants here at present are bearing six or eight hundred large heads of bloom, and trusses of blue, pink, and white may be seen on the same plant; but in my opinion this does not look so well as a mass of blue or pink. The nature of the soil is said to rule the colour of the We have plants standing not 2 yards distant, the one producing deep blue flowers, the other bright pink. The soil in both cases is to all appearance the same. During last winter when the thermometer was repeatedly down to 10° we were much afraid our fine specimens of Hydrangeas would be injured as they were not protected, but they are finer this season than they have been for a long time.—J. MUIR, Margam.

GRAPES CRACKING.—I see by a paragraph in Mr. H. Weir's letter on "Grapes without Fire Heat," that he is troubled with various means to cure the evil, but without much success, till my gardener this season, when the Grapes were fairly on the to become ripe, tried cutting away from one-third to onehalf the stalk for about an inch in length close to the point where the stalk starts from the Vine. This had the desired effect, the cracking was immediately stopped.—MADRESFIELD.

AUTUMN FRUITS AND ROSES.

LITTLE, if any, fruit has ripened to perfection, and much has not reached maturity. Pears have failed most generally, except in exceptional situations or in very sheltered suburban gardens. Plums have been fairly plentiful; Apricots generally very scarce. On two trees, however, that had been kept netted late and long some twelve or fifteen dozen were gathered; from others not similarly protected two or three single fruits could hardly be obtained. But there were no glowing colours, no freckled cheeks, no real amber about the Apricots of this strange season; not a dish could be obtained for the table. We preserved them all as the best means of using them, giving them and all other fruits additional time to expel all unnecessary moisture by rapid boiling, in addition to the allowance of equal weight of sugar for fruit. On some old Apple trees there is a quantity of small fruit. On dwarf standards Cellini and King of the Pippins are the only varieties that have yielded, and every variety of fruit is at least a month late. A few Peaches of fair colour, though some are spotted and cracked, may be seen on our wall.

Visiting the vinery of a neighbour the other day we tasted a sweet and sugary Green Gage Plum of good flavour-one of many that had been for about three days in a temperature of from 65° to 70°. Some small Melons had done well, and a green Valencia was highly and delicately flavoured. small orchard house Peaches though perfectly pale had attained a great size. The gardener measured one for our satisfaction; it was 10½ inches in circumference and weighed 8 ozs., a Walburton Admirable.

Roses are nearly over. There is no real aftermath this autumn; but, spite of unhealthy shoots, spotted leaves, rusty There is no real aftermath this foliage, and caterpillars here and there, Roses have done well, though they cannot bloom freely so late. Devoniensis is still lovely and abundant; Beauty of Waltham, Duke of Connaught, and many others besides La France, give me a fair supply for the smaller bouquets one has now to be content with. Wonderful has been the tenacity of the Tea Roses, and though only I record my experience for the sake of others who may be tempted to decide too hastily that their Tea Roses have perished, as some notable contributors to the Journal have told us they did decide in the late disastrous spring. Then I, too, thought I had lost several of my collection. True some had utterly died, but several that I left in being to all appearance completely dead revived, and two or three of them are now fairly strong plants. One in particular—Karoline Kuster—that I pulled out of the ground showed a bud at the base. I carefully replaced it in April, and now it is just coming into healthy bloom. And now I am full of hope for the future. All the summer I have been working every spare inch of ground for more Roses, and now the catalogues are upon us, with their new and old lists. It is a little difficult to select

where one would like to have many.

Fragrant and free-flowering varieties tempt me most, though form and colour are also irresistible. Still, I rather like two or three trees of known good hardy and free qualities, so as, since my space is small, to be sure of having late and early a good

supply of favourite blooms.—A. M. B.

PROPAGATING HEATHER.—When at Glengariff a fortnight since an American came up to a party of gentlemen and asked if anyone could inform him whether Heather would grow from seed, as they had no Heather in America, and it would be a great curiosity if he could introduce it, as no one seemed to know anything about the propagation of it. I answered him that if he had asked the question six weeks since I could not have answered it, but that I happened now to know for certain that it would grow from seed, as I had observed a large patch of young Heather growing in a sand quarry where none had ever been observed before. The seed had dropped from a stack of Heather, and the ground was now covered with plants, some of which were in bloom. As he did not know much about collecting the seed I went up the mountain, and in a short time half filled my pocket with the ripe seed and dead flowers; and as the American was leaving the next day, I suppose by this time the seed is consigned to American soil. makes a pretty edging to borders, and admits of being trimmed. Thanks to Mr. Luckhurst for reminding us it will grow from seed.—OBSERVER.

POTATO CULTURE.

NEARLY half an acre of fertile sandy loam land was divided into two equal portions. One portion was planted wholly with Sutton's Magnum Bonum; some of the rows were 3 feet, others 2½ feet apart. The remaining portion was cropped at the same time with the following varieties in pretty equal proportions:—Dalmahoy, White Rock, Soden's Early Oxford, Suitons' Hundredfold Fluke, King of Potatoes, Snowflake, and Rivers' and Myatt's Ashleaf. Planting was completed before the end of March. The crops were raised in the first and second weeks in September with the following results:—The Magnum Bonum Potatoes were all but free from disease, several consecutive rows presenting not one specimen of a bad tuber. They were of good uniform size, with very few small tubers, and averaged from eight to twelve to the root. This is the third year that I have grown this valuable Potato and with a similar result, excepting that the produce is somewhat less this year than that of the two preceding.

With regard to the other varieties, grown as I have said, side by side and under precisely similar conditions, the crop of Rivers' and Myatt's Ashleaf are very satisfactory, with a very occasional specimen only of disease. King of Potatoes and Snowflake are diseased to a very serious extent, whilst Dalmahoy, White Rock, Soden's, and the Fluke are so extensively affected as hardly to pay for the cost of digging. Indeed, we are all of opinion that the yield of these latter is scarcely equal

in amount to the seed that was planted.

Of the Magnum Bonums the yield in the rowsplanted 21 feet apart was quite as good as in those 3 feet apart. A certain number of the rows of the Magnum Bonum and of Rivers' Ashleaf were earthed up in the usual way, but the greater number were, owing to the constant wet weather, not hoed at all. The only difference in the yield of the rows thus differently treated was, that certainly the largest Potatoes of Rivers' were in those rows that had not been earthed up. On this point I have some-times been struck whilst watching the process of earthing, at seeing many of the underground shoots that bear the tubers ruthlessly cut off by the hoe. It is reasonable to infer that some of the early points which would have borne the largest Potatoes have been in this way sacrificed. However this may be, I should be inclined to make further experiments before concluding that earthing up is necessary in all kinds of soil. The experience of some of your professional writers would be most valuable if they would kindly give it on this point.

Our experience this season in regard to the size of the tubers planted is also a little at variance with the usual recommenda-tion. It so happened that the Rivers' Ashleaf Potatoes in-tended for seed found their way long ago into the kitchen, and the only tubers available for planting were those set apart for pigs, being about 1 or 1½ inch in length. "Plant them all, sir, they will do as well as any," said my gardener. And he was right. Some splendid Potatoes are the result; one now before me I measure as I write, it is 4½ inches long, 6½ inches in circumference, and weighs 5 ozs. There are many still larger

specimens.

I will only add, that owing I presume to the wet season, several of the plants of the different sorts bore tubers on the green stems. A tuber being merely an irregular dilatation of an underground stem this result is intelligible, especially in the general absence of light this summer; but I observed in every instance, I think, where these aërial Potatoes were formed none were to be found underground.—A SURREY PHYSICIAN.

HOYA CARNOSA.

With what ornamental plant can I clothe the back wall of my vinery quickly? To this oft-repeated question I would always answer, Hoya carnosa. It is an evergreen, its foliage is handsome, its flowers perfectly lovely, its growth robust and free. It requires no border, a cubic foot of soil with plenty of drainage in a pot will suffice for a plant which has to cover an area of 300 square feet. Every shoot is self-supporting, putting forth roots and clinging to the wall just like Ivy. How can we feed these branch roots? They absorb moisture

from the bricks; the syringe must therefore be used freely throughout the season of growth, not using pure water, but weak, clarified, liquid manure—thus charging the wall with fertilising moisture that is neither offensive nor unsightly, and which tends wonderfully to promote the vigour of branch and foliage. My favourite agent for this purpose is Lawes' Grass manure, which dissolves so quickly that the water becomes clear as crystal in an hour or two after it is thrown into it. The Hoya blooms abundantly in the shade, a truss of about twenty flowers springing from the axil of every alternate pair of leaves all over the plant, for the truss stems never fall off but are persistent, and once formed continue to yield an annual crop of flowers, gradually becoming elongated, each circle of flowers leaving its impress so that the stems of old plants upwards of a dozen years old may be seen still going on bearing flowers as fine, fresh, and abundant as those on the young shoots. The velvety star-like white flowers, so exquisitely suffused with a delicate pink tint, embossed with a central star with five white waxen points and a minute central point projecting from a pencilled rosy crimson disk, each having a large transparent globule of liquid nectar suspended from its centre, and so sweet as to prove an irresistible attraction to the children, combine to form one of the most beautiful objects in the garden. -KDWARD LUCKHURST.

THE FIG.

I OBSERVE that an inquiry is made for information regarding the non-ripening of Figs upon a tree covered through the winter with young Figs. I give you the results of my own observations, and a mode of treatment by which I have gathered ripe Figs from a tree which, though planted many years and in vigorous health, had never previously ripened the abundant crop of young Figs with which it had been covered during the winter and spring. The tree is a standard tree, which is perhaps 20 feet high, but has evidently been partly cut down before I purchased the property at Budleigh Saltarton, South Devon, where it grows. I go to this house only in July or August, and each year I observed that the young Figs appeared before I left, but the gardener told me that though the tree had been covered with them through the winter all of them fell off in the spring. I observed that soon after the first young Fig made its appearance a second smaller Fig appeared by its side. I knew that in its own country the Fig tree bears two crops of Figs. Speculating upon these facts I adopted the plan of rubbing off the first Figs before the appearance of the second. In about a week, as far as I have observed, after the destruction of the first Fig another Fig protruded close to the scar left by the removal of the first. The result has been that I now get ripe Figs, but in no great quantity, though the tree has been still through the winter laden with these second Figs. I do not know the name of this Fig, but it is of a russet colour outside and purplish within, and very fine in flavour. The Figs are very large, and I weighed ripe ones this year; one of 84 ozs., another of 6 ozs. It appears to me that the explanation of the success of the above proceeding is, that as this particular kind of Fig is a very large one, if the first, which cannot ripen in the open air in England, drops off it leaves a scar so large that the attachment of the stalk of the second or riper Fig is so interfered with that its stalk perishes, and so the Fig drops off. It may be that the tree of your correspondent bears large Figs, and that my experience may be useful to him. If he succeeds by this plan it would be interesting to have the fact recorded in your columns.—SAMUEL CROMPTON.

THE SYRIAN DESERT IN SPRING.

THE following extract, from Lady Anne Blunt's "Bedouins of the Euphrates," may interest your readers. The district spoken of, the Hamad, is due east of Damascus, and lies between latitudes 34° and 30°.—A. B.

"At this time of year (in February and early March) if the season is favourable the Hamád is one of the most beautiful sights in the world—a vast undulating plane of grass and signs in the works. The purple Stock, which predominates on the better soils, gives its colour to the whole country, and on it the camels feed, preferring it to all other food. The hollows are camels feed, preferring it to all other food. filled with the richest meadow grass, wild Barley, wild Oats, and wild Bye, the haunts of quails, while here and there deep beds of Blue Geranium (Bohattery) take their place, or tracts white with Camomiles. On the poorer soils the flowers are

not less gay; Tulips, Marigolds, Asters, Irises, and certain pink Wallflowers the most beautiful of all—cousins each of them to our garden plants. For it was from the desert doubt-lessly that the Crusaders brought us many of those that we now consider essentially English flowers. Through this, as through a garden, the vast herds of camels with their attendant Bedouins move slowly all the spring; and the mares, starved during eight months of the year, foal, and grow fat upon a certain crisp grass which grows among the purple Stock, fine and dry and sweet as sugar."—(Page 166, vol. ii.)

HARDY PLANTS AT THE EXPERIMENTAL GARDEN.

THE following plants, received at the garden last spring principally from Mr. Smith of Worcester and Mr. Ware of Tottenham, have proved very attractive and of easy management, and being free growers have become well established in a few months; most of them have been previously grown and tested by me in a different soil. It will be seen that the majority are simply varieties of our indigenous British plants, but are none the less valuable on that account.

Achillea Plarwica fl.-pl.—One of the prettiest and most perpetual-blooming hardy white flowers grown, and very useful for cutting; and if I were confined to growing six hardy

herbaceous plants this would be one of them.

Caltha palustris ft.-pl.—Both the large and small-flowered varieties have perfectly formed bright golden yellow flowers, the latter being dwarfer and preferable. Likes a cool soil.

Dianthus barbatus magnificus (double dwarf dark carmine Sweet William).—A bed of this in the Bedford Cemetery last year was for nearly three months a blaze of colour, and has this season been again the attraction of the place. It is easy of propagation, very free, and in all respects worthy of cultivation either for beds or borders; but sunshine best developes

the brilliancy of its colour. One of the very best of the six.

Erysimum Barbarea fl.-pl.—A very old-fashioned border flower. The double yellow Rocket does best in a cool but open

Geranium pratense ft.-pl.—Of this there are two varieties, one being fuller and of more perfect form, but not quite so bright in colour as the other; the first being greatly preferred, however, by me. It lasts a long time in bloom, will grow any where, but likes a cool situation best. I should place it in the foremost of the six.

Letus corniculatus fl.-pl.-This when grown en masse is a most striking, dwarf, summer-flowering plant; is at home on a dry bank, and does well on the sunny side of a rockery.

Pyrethrum (Chrysanthemum) uliginosum.—This is a tall-growing hardy Composite of the Reine Marguerite type, producing very freely in late autumn flowers with white rays and yellow discs almost as large as a good size Dahlia. Most striking at this season, and very suitable for the back of a border or shrubbery. Should be more grown.

Salvia pratensis lupinoides.—One of the prettiest of all the Salvias, having purple and white labiate flowers freely pro-

Spiraea Filipendula fl.-pl.-I should select this as another of the best six hardy herbaceous plants, as it is very pretty, dwart, free, and easily propagated. Does best in a dryish situation.

Spiræa Ulmaria fl.-pl.—Almost equal to the last, but is taller and likes a moist soil. The flowers are also scented, but not

quite so much so as the single variety.

Trollius Fortunei fl.-pl.-I know of no flower of its exact colour, as it reminds one a good deal of the setting sun. It is

the prettiest of the tribe.

One of the best hardy annuals I have grown is the fine double variety of the common pot Marigold, called Le Proust. The flowers are very perfectly formed and of a curious buff colour, with petals tipped brown and streaked orange and bright yellow, and will of course grow anywhere. - T. LAXTON, Bedford.

BLACK ALICANTE GRAPE FAILING IN A COOL HOUSE We have tried this variety of Grape in a cool house for the last three years. Each season it has produced plenty of bunches, but the berries have never set or become larger than peas when ripe, although the bunches were well shaken and brushed with rabbit tails when in bloom. Lady Downe's, Hamburghs, &c., have not shown this failing in the same house. I therefore think the Alicante is not a suitable Grape to plant in cool houses in all cases. We have lately inarched Pearson's Golden Queen on all our Alicantes, and we expect better results from it.—A KITCHEN GARDENER.

PORCHESTER, ITS CASTLE AND ITS POSY GARDENS.

PERHAPS many of my readers know South Hants, and particularly Portsmouth. On the landward side of its renowned harbour the visitor cannot help seeing a wide-spreading Castle, "a noble wreck in ruinous perfection," with a good belt of trees around it, forming a green setting to its grey walls and towers. But one tower is so much larger than the rest that it at once attracts and fixes your attention. A large, high, massive tower it is. There it stands, "four-square to every wind that blows;" and there it has stood. How long shall we say? Well, I hardly know; but we do know that Porchester Castle existed in the time of the Romans, and from its seaward gate probably embarked the legion for the siege of Jerusalem. We do know the Castle was first a Roman, and then in succession a Saxon, Norman, and English fortress, and a prison for the French taken in the Napoleon wars. I was desirous of seeing Porchester town and examining its Castle for a special reason, for I learn that the former has one marked and peculiar industry the cultivation of nosegay flowers, supplied in vast numbers to the dwellers in Portsmouth and tourists. Having obtained a general view from Fort Southwick I descend and visit Porchester lying beneath. The town is not striking to a stranger's eye; it is low-lying and straggling. One thing attracted my notice, that is the great proportion of flowers in the cottage gardens. But like all strangers I must hurry on and see the Castle. Fortunately I have a fine day—a break in the bad weather; a brief one it proved, in this summer suitable for the growth of Ivy and slogs, but not suitable for flowers and fruit and sight-seeing. It is autumn, but had it been spring I am told that the old Castle walls would have been ablaze with Wallflowers growing abundantly and unchecked. I enter by the land port or western tower, and learn that the walls of the Castle enclose a space of over eight acres; and I can well believe it, for the greensward within is wide and large. In the further part to the right is the church. The space inside the Castle looks like a square flat field, in which cattle calmly graze. Porchester Castle is now a great place for excursionists.

Vast are the remains. There is the Norman court, the citadel, banqueting hall, Queen Elizabeth's tower, and other towers; but the eye still is most caught by the great Saxon tower, roofed in, with storey above storey gained by flights of stairs. In all there are in it fourteen rooms. This was the principal perison in the war time, and in the Castle were confined during the French wars as many as eight thousand men.

I look into the church, a fine Norman building in the form of a cross, but one arm of which, the south transept, has long since yielded to time and decay. I leave the Castle in search for what I may call the principal posy garden of the place. It belongs to Mr. Martell, who shows me some of the posies or nosegays which are ready for sale—good-sized nosegays they are of the flowers now in season. There is one peculiarity in their make-up: instead of an edging of white paper, formallooking and artificial, all Porchester posies have an edge formed of Box or other evergreen. This looks so unartificial; and, besides, green always gladdens the eyes. During the year thousands of excursionists visit Porchester Castle and purchase nosegays. But besides the sale of posies to excursionists there is a regular demand for flowers in this form in Portsmouth. This is well, for flowers brighten up sad and sick rooms; they cheer and solace; they make the little town parlour, often stiff and tasteless in its furniture arrangement, bright and cheerful. Porchester posy gardens do much good, then, in a quiet unobtrusive way; so we will re-echo Kit Marlow's words, written though they were over three hundred years ago-

"I will make thee beds of Roses, And a thousand fragrant posies."

I am taken by Mr. Martell into his nursery garden—unique in its way, everything being cultivated for a special purpose. His object, he told me, was to have a quick succession of flowers throughout the year to make up into nosegays; all suitable, but unsuitable ones are discarded. The size of the ground thus cultivated is eight acres, of which one acre is devoted solely to Pansies. Here, too, were large beds of Pinks, Anemones, Carnations, Phloxes, and many other flowers, all to come in their season, and seldom enough flowers are to be had. Hence every cottage garden is a bunch of flowers. The

old Castle brings the demand in a great measure, and Porchester taxes itself to create the supply. There is a great demand for old China Roses, so Mr. Martell has an outer garden given up solely to them. Flowers here are literally the staff of life; every garden is full of them, and the object of all is to get more and more. Poor children are brought up to tend and take care of the flowers. It is not with them as with the girl in Tom Hood's poem—

"Poor Peggy hawks nosegays from street to street, Till—think of that, ye who find life so sweet— She hates the smell of Rosss."

No! for the Porchester Peggies love their smell, as it leads to bread and butter.

Mr. Martell is carefully cultivating a white Polyanthus with yellow eye, which is not yet in trade, and which he believes that he alone possesses. His garden is not one easy to forget from its peculiarity. Here are old-fashioned flowers in abundance, such as Sweet Williams, and Daisies, and Stocks—everything suitable for the nosegay. Upon my mentioning my interest in fruits Mr. Martell told me that he knew those whose Cherry trees realised usually \$40, had only 9s. worth on them this year. He also said that in his part of the country the Black Diamond Plum had stood the wet better than any other. Thus gathering information I wander through this peculiar but interesting nursery, this posy garden so curiously connected with Porchester's ancient Castle.—WILTSHIER RECTOR.

STRAWBERRY CULTURE.

I Do not wish to enter into the discussion in previous issues on Strawberry forcing, though I have read the different opinions that have been expressed; but I will observe that to be successful in Strawberry forcing we must from the commencement never lose an opportunity of improving the plants. If we were to work with the same enthusiasm with plants for outdoor quarters as we do in the case of plants for forcing we should have much better than the usual results. As a rule, where plantations of young Strawberries are made in autumn no fruit is expected therefrom till the second summer after, where no forced plants are made use of. By selecting runners for fresh plantations in the same way as for pot work — working against time, having the plants early established—a good stroke of work would thus be done. A few years ago in a fresh quarter, which I had planted late in autumn, the succeeding summer I found by the foliage some varieties were mixed; this not being satisfactory I pulled out the plants not required and transplanted some early estab-lished runners. The succeeding year the latter all bore a good crop. A few weeks ago I had a fresh plantation made, which was the first opportunity I had. Every plant was lifted with a ball of earth; through this they never flagged a leaf. I eventually gave them a watering with liquid manure. The stronger plants have been throwing out runners for some time past, which I had picked off; and if I do not have a good crop next year I feel satisfied I shall lose nothing by having taken the first chance in planting-M. A.

It is a practice in many gardens after the fruit is gathered from the Strawberries to clear away any weeds that have sprung up, and to divest from the permanent plants all runners after the stock for forcing has been layered and the necessary quantity for fresh plantations has been obtained. This practice we adopt and recommend. Where useless runners are allowed to remain until late in the season before being removed they rob the parent plants considerably, and exclude valuable light from the crowns of those intended to produce a crop the following year. Another system we have seen practised is, after the fruit has been gathered a line is laid down, and a man commences with his spade and chops off a large portion of the leaves, the runners as well. This system, we think, cannot be too strongly condemned. Much more harm results from it than allowing the runners and all to grow together until the Strawberry is thoroughly at rest. How can plants develope plump and prominent crowns when divested of their foliage when in full growth? The Strawberry, like all other plants, will ripen its own foliage, and can then be cleared off without practising the unnatural system alluded to when the foliage is immature. -SCIENTIA.

WELLINGTONIA GIGANTEA.—It may interest Mr. Campbell (page 272) to know that none of the Wellingtonias here are so tall as the highest at Muckross, but some of them are more in

girth, the largest measuring 10 feet 9 inches round 18 inches from the ground. This tree is only about 40 feet high, and some of the cones are in clusters of two dozen or more. Are they usually produced in this manner?—J. MUIR, Margam.

ABOUT LIVERPOOL .-- No. 5. WHINCOTE.

BEFORE noticing the undermentioned gardens it is necessary to correct a printer's error that ought not to have been made nor passed, in the notes on Mr. McIver's gardens last week. Mr. Tunnington, not "Dunnington" as printed, is the skilful manager of those gardens. Equally skilful as a gardener, but his charge is much less extensive, is Mr. Mease, gardener to C. W. Neumann, Esq., Whincote. This garden though small is evidently cherished by its owner, and better "all round" practice is not often seen than in this variedly in-teresting enclosure. Besides the formal modern flower garden, which was effectively planted, there is a section devoted to hardy herbaceous plants, which being select, well cultivated and attended to, constituted the most attractive portion of the ground. Potentillas in choice variety, Irises of the Kæmpferi section, Dianthuses, Delphiniums, Campanulas, and various other border flowers tastefully blended, produced an effect as rich as it was pleasing. The conservatory was also very gay, the most notable plant being Lapageria alba trained to the roof and bearing five hundred flowers—a charming sight. Rock and alpine plants are also represented in suitable positions, and the large, undulated, and excellently kept lawn "set off"

the flowers to great advantage.
Under glass the practice is equally good. Not an unhealthy or unpresentable plant is to be seen, while not a few of the specimens are worthy of a place at any exhibition. Some of them won high honours at the Liverpool Show, which was cer-tainly one of the best exhibitions of the year, and were alluded to in the report on page 106. Others, smaller because of more recent introduction, are represented in the best health and Quite as noteworthy as the plants are, or were, the The house of Muscats was one of the finest in the district, the bunches large, well formed, and full, with fine berries of excellent finish. Thinly disposed spurs, ample and fully developed foliage, with heavy top-dressings of rich manure on the borders, are the leading points of culture which have produced such highly creditable results. The top-dressing was a mass of active roots, which were copiously supplied with liquid manure, and the healthy foliage and grand bunches overhead told how greatly the Vines enjoyed this generous fare. Peaches are extensively and well grown under glass, and overfield the Chyrsenthemums by their standings and and outside the Chrysanthemums by their sturdiness and generally good condition gave promise of fine blooms. Each plant is limited to three stems, which were strong without being excessively exuberant, experience having proved that

over-luxuriance is productive of coarse blooms.

Such is a very brief outline of this garden, which is well worthy of a visit, and of recognition, on account of the excellence of the practice in every department.

WOOLTON HALL

In few places "about Liverpool" is gardening conducted in a more spirited manner than in this, the establishment of J. R. Leyland, Esq. The mansion is surrounded with extensive lawns and noble trees, and herbaceous plants are largely grown in borders at the front of the shrubberies. A panelled flower garden is formed near the conservatory, which adjoins the mansion, and the massing of flowering plants and carpet beds is well carried out. The two central beds in the designs were planted with the fine old Salvia patens, which enjoyed the wet cool summer, flowered with great profusion, and was both elegant and rich. It is not necessary to dwell on the contents of the conservatory, because all such well-furnished structures contain much the same class of plants at the various seasons of the year; but it may be useful to state that the wall of the corridor connecting the building with the mansion is covered with Cissus atlanticus, which is never injured by the gas that is regularly burned there, and from the effects of which most other plants suffer considerably.

It is, however, the newly erected glass structures that constitute the great feature of the gardens. The houses are extensive, and some of them exceptionally large. They have all been planned by and erected under the immediate superintendence of Mr. Faulkner the gardener. Span-roofed houses are provided for stove and greenhouse plants and Orchids, of I anticipate it will be long-bearing. In height it has not ex-

which good collections are being formed and well grown; pits for Pines, Melons, &c.; and splendid vineries, half-span, the front rafters being 22 feet in length. The Vines are in their second year, and are extremely strong. All the leading varieties are planted, and grand Grapes ought to be produced in due time. The strong shelves along the back of the range contain boxes planted with Tomatoes, which are trained up the shorter north roof and produce heavy crops. Herbaceous borders are formed alongside the walks in the kitchen garden, and all requisite conveniences are being provided for forming a very complete garden. In a large square enclosure are frames and Chrysanthemums. Six hundred of these plants are grown, including all the best varieties in cultivation; and if Mr. Faulkner enters the exhibition lists this autumn he ought to be a very formidable competitor. The plants were in excellent health, and were evidently receiving that good attention that is bestowed on everything in the establishment.—J. W.

ROCK ROSES.

MANY species and varieties of the large genus Helianthemum possess sufficient attractions to render them worthy of more attention than they generally receive for planting in a variety of positions in the garden. The fugaciousness of their flowers is their chief failing, and doubtlessly that to a great extent prevents their being more appreciated; but although the flowers are of short duration individually, they are produced in abundance, and the colours are bright and varied. Most of the species are dwarf, erect, or trailing shrubs, and require a some-what sandy or light soil. They succeed well on an ordinary rockery in nooks where more delicate plants would not thrive. They may also be planted in the mixed border or on banks, or in fact in any position where the soil is not too heavy. The popular name Rock Roses has been bestowed upon them because, owing to their five petals and numerous stamens, they bear some resemblance to the single wild Roses.

The best of the varieties and species are the following:— H. vulgare venustum, flowers small, of a peculiar bright crimson-scarlet colour, stamens yellow; very effective in dense masses. H.v. macranthum, flowers white with a yellowish tinge, very abundant. H. v. serpyllifolium, leaves small, bright green and smooth; flowers pale yellow. H. v. roseum, a compact little plant with numerous pretty rose-coloured flowers. H. v. sulphare with numerous pretty rose-coloured howers. H. v. suiphureum, flowers most profusely produced of a fine pale sulphur colour. H. v. Lucy, leaves dark green; flowers semi-double, purplish pink. H. libanotis, long linear dark green leaves, flowers small, yellow; a very distinct and old species. H. rugosum, a small trailing shrub, flowers bright yellow with a dark marcon centre; attractive and pretty. H. polifolium, downy leaves, white flowers, and yellow stamens, very pretty; this is a British species. There are in addition to those enuthis is a British species. There are, in addition to those enumerated, several very good double forms of H. vulgare that are bright and rather more durable than the single varieties.—L. C.

PROPAGATING NEPENTHES—MATLOCK SPAR.

In your last week's issue I notice an inquiry by "YOUNG GARDENER" as to the best means of propagating Nepenthes. I have found cuttings of those plants to root most freely when taken off with a good leaf attached, inserted in "Matlock spar," and afforded a brisk bottom heat.

The spar I use for the purpose is of the kind so largely employed in this neighbourhood for surfacing the asphalt footpaths to give them a whitish appearance, and which has been crushed to the size of Peas. I find that most plants root very freely in that material. The cuttings of Crotons root and grow remarkably quickly if inserted in it, and I have seen leaves of the same without any wood attached that have lain for a short time upon it, throw out roots into it in the same manner as a Begonia or Gloxinia root would do. I have found a number of plants which are usually considered as being difficult to pro-Pagate, such as the new Aralias, Reidias, Terminalias, and Pavettas, root most freely in this material if they are kept close and a moderately briak bottom heat is maintained.— W. K. WOODCOCK, The Gardens, Thornbury, Sheffield.

PEA R. GILBERT.—This blue wrinkled Pea, received at the Experimental Garden from Mr. Gilbert, has proved a very fine and productive late or late main crop variety. In addition to its other good qualities I can testify to its excellent flavour, and

ceeded 3 feet—a great advantage in a season like this, when many warieties have grown quite out of reach, and it has been almost impossible to find sticks tall enough. In several instances here the ordinary 6 feet Peas sown 6 feet apart and staked proportionately have quite filled the intervening spaces.—T. LAXTON.

THE BEDDING AT THE CRYSTAL PALACE.

OWING to the elevated and exposed position which the park and gardens at Sydenham occupy, the sunless and rainy season has severely affected the flowering plants that usually produce such a brilliant display. The beds in the Italian garden bore a very dull appearance, the only plants there that had any approach to brightness being the Calceolarias (var. Golden Gem), which have flowered profusely, and they still continue very effective. Several of the beds have been planted with carpet designs that would no doubt have been very pleasing under favourable conditions, for the designs are elegant, but the plants have not well filled up their allotted space, consequently giving a somewhat patchy appearance. But these remarks will not apply to the Dahlias near the rosery, for although the growth has been somewhat stunted and the flowers are perhaps not quite so fine individually, yet they are very abundant, and their colours extremely clear and bright. The large circular beds which these plants occupy are un-commonly attractive; most of the best varieties are represented, including numerous shades of pink, crimson, scarlet, and white. One large bed of irregular form near the above was particularly noticeable; it was planted with variously tinted Phloxes, dwarf Sunflowers, numerous brightly coloured Dahlias, the glowing Tritoma Uvaria, and a few Hollyhocks intermixed, and a more pleasing, cheerful, and effective combination of colours, especially when viewed from a distance, could scarcely be imagined.

Around the rosery the beds present a rather better appearance than they do in the Italian garden, partly because the majority are carpet beds, and the plants most freely employed are Mentha Pulegium gibraltarica, Herniaria glabra, and Golden Feverfew, all of which are in a measure independent of the weather. The designs, too, are of a simple character; and that is an important point, for an intricate device never looks well unless clearly defined and filled out, and in a season like the present has been that is almost impossible. On the lower portion of the slopes two circles are very pretty, planted with variegated Gazanias intermixed with Lobelias in one, and in the other with Iresine Lindeni, the contrast of the orange flowers and variegated foliage of the Gazanias with the darkleaved Iresine and blue-flowered Lobelias being especially pleasing. The border immediately surrounding the Ivy-covered arches is planted with triangles of Pelargonium Bonfire and Christine alternately, margined with lines of Pelargonium Golden Superb Nosegay, Iresine Lindeni, and Pyrethrum, with central alternate squares of Tagetes and Centaureas, the outer edge being formed of Lobelias and Echeverias. Viewed from the lower walk this border has an agreeable appearance.

The general aspect of the park and lawns is extremely good; the shrubs and trees have made abundant growth, and the well-kept turf is as close and fresh as could be desired. Near the central walk we noticed a novel and yet excellent combinarion of plants in a large bed. The centre was occupied with Phloxes, Sedum spectabile, Retinosporas, variegated Maples, Aralias, &c., intermixed and edged with small Retinosporas and Euonymus radicans variegatus. This is an idea that might be carried out with effect in many other places.—L. CASTLE.

PORTRAITS OF NEW AND NOTABLE PLANTS.

GERANIUM ATLANTICUM. Nat. ord., Geraniaces.-"G. atlanticum is a native of Algiers, where it was found in rocky by Munby, on the peak of Mérid by Choulette, and in Oak forests near Blidah by Lefebvre. A perennial herb, clothed with rather appressed silky hairs, eglandular; rootstock a small woody tuber with dark-brown bark."—(Bot. Mag., t. 6452.)

CHIONODOXA NANA. Nat. ord., Liliacese.—"A native of

the mountains of Crete, at an altitude of 5000 or 6000 feet above sea level, flowering in the neighbourhood of the melting snow in May, and consequently perfectly hardy in our English gardens. It was discovered by Sieber, an Austrian traveller, who collected plants largely in the island about the year 1820, and who confounded it with the Caucasian Puschkinia scil-Leides, and figured it under that name in his published travels. For horticultural purposes it is far inferior to C. Luciliæ (' Bot. Mag.,' tab. 6433), the flower being much smaller, and the whole habit of the plant more slender."—(Ibid., t. 6453.)

PRICHOTRIA JASMINIFLORA. Nat. ord., Rubiaces. —
"P. jasminiflora was discovered by Libon in the province of St. Catherine, in South Brazil, in 1860, and introduced by Mr. Linden."—(*İbid. t. 6454.*)

ODONTOGLOSSUM MACULATUM. Nat. ord., Orchides.— Native of Mexico.—"Of the genus twelve species are known, including some of the finest, which are yet to be introduced into

cultivation. O. maculatum has been long cultivated at Kew, and flowers freely in June."—(Ibid., t. 6455.)

VERONICA LYALLII. Nat. ord., Scrophularinese.—"It inhabits both the larger islands of New Zealand at elevations of 2000 feet and upwards; and we have specimens which cannot be distinguished specifically in a dry state, gathered by Colenso on rocky cliffs at Patea, and from the top of the Ruahine mountains. V. Lyallii was raised from seed by Mr. Isaac Anderson-Henry, F.S.A., and flowered with him in May of the present year for the first time. It is a slender subcrect or creeping branching plant, glabrous or with the stem pubescent; branches rather woody, prostrate and rooting or ascending."-(1bid., t. 6456.)

ARISEMA GÁLEATUM. Nat. ord., Aroidese .- "It is a native of Sikkim, from whence tubers were sent to Kew by Mr. Gammie, through Dr. King of the Calcutta Botanic Gardens. It flowered in Kew in May of the present year, as it also did in the gardens of the Boyal Horticultural Society, Chiswick."-(Ibid., t. 6457.)

ROYAL HORTICULTURAL SOCIETY.

THE exhibits at this meeting were both numerous and good, and many visitors were most agreeably surprised. In the vesti-bule Messrs. Charles Lee & Son exhibited a fine and tastefully arranged collection of Conifers, Euonymuses, and other hardy ornamental shrubs similar to that of last year, and for which a gold medal was awarded. The exhibition will continue until the 24th inst. Near the entrance were Messrs. Lane's magnificent Vines in pots, which attracted considerable attention. In the Council-room were arranged the various collections of plants, those from Messrs. Veitch, Williams, and Bull being especially noticeable; also the extensive collections of fruit from Messrs. Veitch, Paul, Wildsmith, and Goodacre.

Paul, Wildsmith, and Goodacre.

FRUIT COMMITTEE.—H. Webb, Esq., in the chair. The collections of fruit were numerous and good, the large collections of Apples and Pears from Messrs. Veitch and Paul being especially remarkable. Grapes and Pines were also in fine condition. Mr. C. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury, exhibited five handsome well-ripened Smooth Cayenne Pine Apples, weighing respectively 8 lbs. 14½ ozs., 6 lbs. 5 ozs., 5 lbs. 11½ ozs., 5 lbs. 10 ozs., and 5 lbs. 5 ozs. A cultural commendation and bronze medal were awarded. Mr. W. Allen, gardener to Lord Suffield, Gunton Park, Norwich, exhibited two fine bunches of Muscat of Alexandria Grape, weighing together 10 lbs., the berries large and well ripened. A bronze medal was awarded. He also sent a seedling, the result of a cross between Syrian and Alicante. Two bunches were shown, one the produce of a Vine inarched on Two bunches were shown, one the produce of a Vine inarched on Lady Downe's and the other from a Vine on its own roots; the bunch is long and the berry oval. The Committee considered it distinct, but desired to see it later in the year. Mr. Goodacre, Elvaston Castle, Derby, sent twenty-five bunches of Grapes in twelve varieties. The following were very good—Alicante, Bar-barossa, Mrs. Pince, and Gros Colman. For this fine collection a

barossa, Mrs. Pince, and Gros Colman. For this fine collection a silver Knightian medal was awarded.

Mr. Wildsmith, gardener to Viscount Eversley, Heckfield Place, Winchfield, sent twenty-two bunches of Grapes in ten varieties, including Lady Downe's, Trebbiano, Black Hamburgh, and Alicante well finished. This was also an excellent collection, and a similar award was granted. Messrs. Osborn & Sons, Fulham, exhibited a number of small plants of their new variety of Fig, Osborn's Prolific, which well deserves its name; but nothing was awarded, as the fruit was not ripe. Mr. J. Walker sent a fine dish of Pond's Seedling Plum well ripened, also a dish of Red Currants, for which a vote of thanks was accorded. Messrs. Veitch and Sons of Chelsea exhibited ninety-five dishes of Apples in good Currants, for which a vote of thanks was accorded. Messrs. Veitch and Sons of Chelsea exhibited ninety-five dishes of Apples in good condition for the season. They had been borne by trees growing in the Southfield Nurseries, Fulham. The collection included all the best varieties, and a silver Knightian medal was awarded for them. Messrs. Wm. Paul & Sons, Waltham Cross, also staged a large collection of Apples and Pears, comprising a hundred dishes. The Pears were generally unripe. A bronze Knightian medal was awarded was awarded.

Messrs. H. Lane & Son, Great Berkhampstead, exhibited a large collection of Grapes, most of which were in fine condition, but their Vines in pots were most excellent. Six Vines were shown,

all bearing a large quantity of fruit, and generally well ripened and coloured. Foster's Seedling had twenty-eight, twenty-seven, and twenty-six bunches; Black Hamburgh fifteen and sixteen and twenty-six banches; Black Hamburgh fifteen and sixteen good bunches; and Alicante fourteen bunches. For this superb collection a gold medal was deservedly awarded. Mr. J. Perkins, gardener, Thornton Hall, Eye, Sussex, sent a seedling Melon named The Squire, fairly well netted. Mr. D. Beesley, gardener to R. P. Coleman, Eaq., Spilsby, sent a brace of Oucambers named the Improved Manchester Prize of good strain: this was commended. Mr. J. Pond of Jersey exhibited two seedling Shallots, one the Jersey Lily, and the other the Jersey Giant Red. They are to be tried at Chiswick. Herr Ernest Benary of Erfurt was awarded a first-class certificate for a purple-tep Turaip named Early Munich, which has been tried at Chiswick and found to be three weeks earlier than other varieties. A vote of thanks was accorded to Mr. Eads of The Cedars, Northampton, for a dish of Suttons' Giant White Bunner Beans in good condition. Suttons' Giant White Runner Beans in good condition.
FLORAL COMMITTEE.—Dr. Denny in the chair. The duties of

Thoract Committee.—Dr. Denny in the chair. The drates of the Committee were by no means light on this occasion, for very numerous collections of plants were staged. From Messrs. Veiteh and Sons, Chelsea, came an excellent collection of new and rare Orchids and other plants, which included the following:—Mistonia Mosellisms superbs, with large flowers, sepals and petals deep purple, labellum light purple with darker veins—very pretty; a specimen of Coelogyne Massangeans, bearing a large spike of very pale yellow flowers, the labellum being marked with dark streaks inside: Oncidium ornithorhynchum album bearing. a specimen of Cœlogyne Massangeans, bearing a large spike of very pale yellow flowers, the labellum being marked with dark streaks inside; Oncidium ornithorhynchum album, bearing a slender branching spike of small white flowers, with a yellow crest in the centre of the labellum; Oncidium dasytyle, a curious little species with small flowers, labellum yellowish with a dark protuberance near the base, and the sepals spotted with chocolate. A first-class certificate was awarded. A peculiar Orchid, Mormodes Ocanse, flowers borne in spikes, thickly spotted with reddish brown; and Lilium auratum rubrum vittatum, a variety with crimson purple streaks down the perianth divisions. Pachystoma Thompsonii, an attractive Orchid; sepals and petals white, narrow; flowers in pairs on slender peduncles. A first-class certificate was awarded for this and the following:—Cypripedium Spicerianum, flowers small, petals and labellum of a greenish colour, the poeterior sepal white marked with purple; a pretty and distinct species. This group was not very large, but of great interest.

Mr. B. Williams, Upper Holloway, obtained a silver Banksian medal for a large and most interesting group of plants, comprising numerous excellent Orchids, Crotons, Repenthes, &c., the front line being formed of the extremely attractive little Orchid Pleione lagenaria in 49-pots, each plant bearing about eight flowers. Some of the most noteworthy Orchids were the following:—Vanda carrules had two large spikes of pale bluish white flowers; Dendrobium superbiens was bearing a large spike of bright purple lake flowers with twisted sepals; the showy Odontoglossum granda, with six large flowers; Dendrobium bigibbum, a lovely Australian species with nest little bright purple flowers in long slender spikes; Maxil-

six large flowers; Dendrobium bigibbum, a lovely Australian apecies with neat little bright purple flowers in long slender spikes; Maxillaria nigrescens, a species with peculiar brownish-coloured flowers, narrow soute sepals and petals; the attractive Oncidium tigrinum was bearing a long spike of flowers with large yellow labellums and narrow sepals and petals marked with chocolate bars and spots. Among other plants were the hybrid Nepenthes N. Outramians, obtained from a cross between N. Sedemi and N. Hooker; the pitchers are freely produced of medium size and thickly marked with red. A first-class certificate was awarded for it. A good with red. A first-class certificate was awarded for it. A good specimen of the narrow-leaved Croton Rodeckiana, excellently coloured, was also exhibited. The group was backed up with Katakidozamia Hopei, Panax excelsa compacts, Hyphorbe excelsa, and the following, for each of which first-class certificates were awarded:—Cooos elegantissimus, a very graceful species with eleader drooping bright green leaves; and Calamus densus, a distinct and handsome plant. distinct and handsome plant.

Mr. W. Bull, Chelsea, was accorded a vote of thanks for a number of new and rare plants, of which the most noticeable were the following:—Tillandsia Lindeni genuina, with fine purple flowers on a broad flattened spike; Masdevallia velifera, small flowers on a broad flattened spike; Masdevallia velifera, small showers of a curious yellowish brown tinge; Cynoches Warsoe-wiczii, an extraordinary Orchid, one of Mr. Bull's recent introductions. The flowers have no beauty whatever in a horticultural point of view, as they are of a pale green colour, but they are interesting from being of two very different forms. One form is 2 or 3 inches in diameter, with ovate sepals and petals and a heart-shaped labellum, and are borne on a short stiff spike. The other forms is small with a require related filamentous labellum and snaped labellum, and are borne on a snort still spike. The other form is small, with a peculiar stalked filamentous labellum, and the flowers are borne on a long pendulous spike. A botanical certificate was awarded for this peculiar plant. That very fine Oncidium varicosum with a dense panicle of its bright yellow Mowers, Bolles collectis, Oncidium ornithorhynchum, O. macranthum, and Pleione lagenaria were also in good condition. A firstclass certificate was awarded for Adiantum mundulum, an elegant ittle compact Maidenhair Fern with bipinnate fronds; and similar awards were granted to Polystichum lentum, a pretty Fern with bright green pinnate fronds, the pinnæ being deeply serrate; and Adiantum cuneatum dissectum, a variety with deeply cut pinnules.

Several early-flowering Chrysanthemunas of considerable merit were also exhibited, notably the yellow Précocité.

Mr. John Wills exhibited the distinct new Fern Adiantem Bausei, which is supposed to be a hybrid between A. trapesiforme and A. decorum, and was raised by Mr. Bause, the energetic manager of Mr. Wills' nursery at Anericy. The frends have a most elegant drooping habit; the pinnules are large and bright group and being also pendulous they came the plant to appear most elegant drooping habit; the pinnules are large and bright green, and being also pendulons they cause the plant to appear almost as though it was flagging. Mr. G. King, gardener to G. Simpson, Beq., Wray Park, Reigate, sent a number of seedling Colesses, one being especially bright—viz., majestica, with acute leaves, crimson in the centre and margined with yellow. For this a first-class certificate was awarded. Mr. Charles Noble, Baghot, each his dwarf Reco. Output of the Reddern with deriver with derivers. sent his dwarf Rose—Queen of the Bedders, with dark crimson flowers very freely produced. Mr. C. Green, gardener to Sir G. Macleay, Bletchingley, was accorded a vote of thanks fer a specimen of Brunsvigia Josephine, with an enormous unbel of red flowers; and a first-class certificate for Passiflora Hahmi, a nest hidden and the second states and the second states and the second flowers; and a first-class certificate for Passiffora Hamm, a new whitish flower with ovate leaves, velvety green above and purple underneath. Mesers Rawlings Brothers of Romford contribute a collection of Dahlias, that was highly commanded, including many seedlings of great merit. Mr. H. Cannell, Swanley, staged collections of Dahlias, Pelargoniums, and early-flowering Chrysanthemums, and deservedly obtained a bronze Banksian medal.

A cultural commendation was awarded to Mr. J. Walker, nur-

seryman, Thame, Oxon, for a quantity of cut flowers of the fine hardy climber Tropesolum tuberosum, which continues bleeming hardy climber Tropecolum tuberosum, which continues bleening for several months during summer and autumn. Mr. C. Turner, Slough, exhibited cut flowers of a fine yellow show Dahlia, Oppra, and a fancy variety, Queen Mercedes, the florets white tinged with purple. A first-class certificate was obtained by Mr. Turner for an excellent bedding Dahlia named George Thomson, of dwarf habit, and producing large numbers of bright yellow well-formed flowers. He also exhibited flowers of a pretty bouquet Dahlia named Dora, the florets of which were white tinged inside with yellow. Messrs. Wm. Paul & Son, Waltham Cross, Herts, exhibited six boxes of cut Roses, a great many varieties being represented. yellow. Messrs. Wm. Paul & Son, Waltham Cross, here, exminent six boxes of out Roses, a great many varieties being represented. The following were most noticeable for their freshness and substance: — Madame Victor Verdier, Pierre Notting, Madame Clemence Joigneaux, Beauty of Waltham, Duppy Jamain, Alfred Colomb, Marie Baumann, Duchess of Bedford, and Baronne de Rothschild. A vote of thanks was accorded. Mr. Chambers, West-bay Nursery Leissesth acut appears of a dropping variety of he Nursery, Isleworth, sent specimens of a drooping variety of Pteris serrulate cristate, and a plant of Odontoglossum Alexandre, bearing a long spike of about twenty flowers. For the latter a vote of thanks was accorded. Gentiana Andrewsii, exhibited by Mr. G. F. Wilson of Weybridge, received a similar recognition. Messrs. Haage & Schmidt, Erfurt, Prussia, were accorded a vote of thanks for cut flowers of Selvia farinance. thanks for cut flowers of Salvia farinacea.

NOTES AND GLEANINGS.

ACCORDING to the usual custom the SURPLUS PLANTS will shortly be distributed from the London parks, and Kew and Hampton Court Gardens, and if the clergy, school com-mittees, and others interested make application to the Super-intendents they will receive information as to the time and manner of the distribution.

THE WIMBLEDON GARDENERS' SOCIETY held their first meeting of the season on Monday night last in one of the rooms of the well-appointed bothy in Sir Henry Peek's gardens. Sir Henry, it may be remembered, kindly provides tea with substantial accessories to the members attending the meetings. After the repast Mr. Ollerhead in lieu of a paper on gardening delivered a lecture on bees, which was very lucid, comprehensive, and instructive, and was so much appreciated that the members desired that the subject be continued at the next meeting. It is important that gardeners obtain a practical knowledge of bees, seeing that apiculture is increasing so rapidly, and those are fortunate who have the opportunity of gathering instruction on the subject from such a success bee-keeper as Mr. Ollerhead undoubtedly is.

WE have had forwarded to us a sample of Carter's CHAMPION SCARLET RUNNER BEANS grown by Mr. J. Pilcher at Peckham Rye. The pods are very large, fine, crisp, and fleshy, and represent a good variety well cultivated.

—— "J. M." writes as follows on Verren's AUTUMN GIANT CAULIFLOWER:—"This magnificent Cauliflower is again proving itself far superior to any other variety. We have been cutting it during the last two months, and the heads have been very fine."

· WE have received from Mr. J. House, Peterborough an Exhibition CARD HOLDER. It is made of thin brass of an ornamental pattern, the base being so formed that it can be affixed to a plate or dish; the top containing slits for holding

the prize cards securely. It is suitable for attaching to various exhibits at horticultural shows, where the cards are too often simply placed on the dishes, or are fixed above them in some makeshift and unsystematic manner.

In the shrubberies at Kensington Gardens COTONE-ARTER AFFINIS is very attractive at the present time, owing to the numerous dense clusters of small red berries with which the branches are loaded. It is an evergreen or sub-evergreen species, with bright green ovate leaves downy on the under surface, and it attains a height of 15 to 20 feet. It was introduced in 1828 from Nepal, and is closely allied to C. frigida. The berries remain on the tree for several months.

MESSES. JAMES CARTER & Co. inform us that MR. CATLIN'S NEW ZONAL PELARGONIUMS Lizzie Smith, Edgar Catlin, and Fanny Thorpe, which were certificated at the Show of the Pelargonium Society at South Kensington this year, have passed into their hands for distribution.

IT is proposed to present the REV. H. H. D'OMBRAIN with a testimonial in acknowledgment of the services he has rendered in connection with the National Rose Society, and by his numerous writings on floricultural subjects. Subscriptions may be sent to the Rev. Canon Hole (President of the National Rose Society), Caunton Manor, Southwell.

A VERY pretty plant for the mixed border is HYPERI-CUM PATULUM. It is dwarf and erect in habit, with ovate sessile leaves and small cymes of bright yellow flowers, the petals of which are roundish and slightly incurved. Like other species the flowers are of short duration, but to compensate for that defect they are produced very freely. It is a native of Nepal, whence it was introduced about 1823.

In the greenhouse at Kew the small evergreen Myrtaceous shrub, BEAUFORTIA PURPUREA, is now flowering. attractive plant well adapted to pot culture, and thrives in a compost of peat, loam, and sand. The leaves are opposite, narrow, and rigid; the small crimson flowers being borne in globular clusters, and during the latter part of summer and early autumn they continue very bright and pretty.

THE City Press states that the Markets Committee of the Corporation of London, having received proposals for the erection of a NEW FRUIT AND VEGETABLE MARKET at Smithfield, have accepted the tender of Messrs. John Mowlem & Co. for £109,000. The market is to be erected from the designs prepared in the City architect's office, to harmonise generally with the central markets for meat, poultry, and provisions already erected at Smithfield.

- It is strange that the freely-flowering PYRETHRUM ULIGINOSUM is not more frequently seen planted as a background to herbaceous borders or amongst shrubs, as in such positions it appears to great advantage. The leaves are narrow and deeply serrated; the flower heads (capitula) have yellow central florets, and long, spreading, pure white outer florets. As the heads are produced in abundance good clumps of the plant are very effective. The species has been known in this country since 1816. It is a native of Hungary.

MR. H. C. OGLE writes as follows concerning the method of FUMIGATING explained in the columns of the Journal by our correspondent "W. R. F.," on April 24th:— "I find a common 1s. benzoline lamp preferable to a candle on account of the candle wasting away and the flame becoming too low to burn the tobacco.'

DURING the autumn months the PRICKLY PEAR OR INDIAN FIG is common in the London markets. The chief supply of this fruit is obtained from Sicily, where the Opuntia vulgaris grows both in a wild and cultivated state. The peculiar flattened succulent stems grow extremely fast, and the plant is employed in some countries to form fences round the houses and gardens. The inhabitants of Sicily consider it of great value as an esculent.

WE recently saw in Covent Garden Market some specimens of the fine East Indian fruits MANGOES, which are rarely imported except in the form of pickle. This fruit, which when fully ripe is said to be only surpassed in flavour by the famous Mangosteen, is the produce of Mangifera indica, a tree included in the Cashew family. The fruit is prepared in a variety of ways in India, as preserves, jellies, pickles, and in

AT present the herbaceous borders at South Hill are very gay with TIGRIDIA PAVONIA GRANDIVLORA planted in Honorine Jobert and other autumn-flowering plants. This fine variety of Tigridia should be more generally grown in mixed

"WE have," writes Mr. Cowan, "lately inspected some beds in the flower garden at the new park, Gateshead-on-Tyne, which were filled with Godetia Lady Albemarle. The beds have presented glowing masses of colour since the beginning of July, the season having been favourable for this fine Godetia. which is very valuable for bedding purposes."

Mr. HUGH CRAWFORD has been appointed gardener to R. De la Poer, Esq., Kilcronagh, Waterford; Mr. H. H. HURT succeeds Mr. Geddes as gardener to J. Paget, Esq., Stuffynwood Hall, Mansfield, Notts; Mr. W. ROGERS, late Wilson, Esq., M.P., Warter Priory, Pocklington; Mr. EDWARD WILLMET, Berkeley Castle, to C. S. Roundell, Esq., Osborne, Fernhurst, Haslemere; Mr. N. FULLER, late foreman at Possing-worth to Col. Heaven Feethburn Many, Guildford M. M. L. worth, to Col. Hagart, Eastbury Manor, Guildford; Mr. J. H.
JOHNSTON to Madame Lyne Stephens, Upper Grove House,
Roehampton; Mr. G. ORMISTON to the Earl of Selkirk, St.
Mary's Isle, Kirkcudbright; and Mr. A. WATERS to H. Birkbeck Kan Stoke Holy Cross Norwich beck, Esq., Stoke Holy Cross, Norwich.

— ONE of the most charming sights we have seen this autumn is a house of TUBEROUS BEGONIAS at Brambletye. Some of the newer varieties are remarkable for brilliancy of colour, others for softness and delicacy of tint, also for the large size of the flowers and varied colour of the foliage. Mr. Jenks called our attention to seedlings of much promise, some having foliage of a greyish hue with bright pink flowers, forming an admirable contrast to the green-leaved scarlet and crimson varieties.

· LYING on our table as we write is a spray of POLY-GONUM SIEBOLDII, so brilliant in autumnal beauty as to render it worthy of culture for that purpose alone, brief as is its duration, even if it were not the really valuable ornamental plant it is. The leaf has lest its normal green hue, and is now of an orange brown mottled and blotched with scarlet as rich as it is ever seen on the foliage of Ampelopsis Veitchii.

— THE abnormal gloom and LOW TEMPERATURE of the past summer retarded the growth of everything so much that the flowers of most hardy trees and shrubs have expanded out of season. Desfontainia spinosa is now in full bloom, the flowers of Lilium speciosum are only beginning to open, Pampas Grass as yet only affords us a faint glimpse of its silvery inflorescence, and many Hybrid Perpetual Roses are as full of bloom as they usually are early in September.

— A propos of DESFONTAINIA SPINOSA Mr. Prinsep informs us that the plant of it established on the lawn at Buxted Park, and now "nicely in bloom," last winter bore with impunity 22° of frost and full exposure to cold cutting east winds. From this important fact it would appear that this charming addition to our hardy shrubs is available for gardens generally, and its culture need not be confined to the southern counties.

—— OUR correspondent "J. R. S. C." writes:—"I was shown the other day an instance where 'LADYBIRDS' had infested ripe Apricots, half a dozen of those beetles being often found in the fruits gathered. Obviously however, they could only enter the fruit when it had been punctured previously by wasps or other insects; but it was something new to me to discover Coccinellæ under these circumstances, though their penchant for the sugary aphides might indicate that any sweets would be acceptable to them. Several persons have called my attention to the abundance of ladybirds this autumn, so we may hope they have been doing execution amongst the aphides. The too familiar A. rose has been less conspicuous than usual this season; but then, again, the caterpillar of the Rose-leaf roller (Argyrotoza Bergmanniana), has been a nuisance in some gardens."

CHAMÆBOPS FORTUNEI.--If "A GLOUCESTERSHIRE PARSON" wishes his garden embellished with Palms that will stand uninjured the severities of winter without protection he should plant Chamzerops Fortunei. This Palm has stood out for many years in the nurseries of Mesars. Backhouse & Son of York, and not only grows well but blooms regularly, and seems quite at home. The soil at York is of a light sandy nature, which is doubtless favourable to any plant of doubtful hardiness. I think it is worthy of note that while such shrubs as clumps. Its fine scarlet flowers contrast well with Anemone Laurels, Aucubas, Laurustinus, Yuccas, &c., were much injured

810

during the past winter, this Palm did not seem to feel the severity of the weather, but grew and bloomed as usual.—
SUSSEX GARDENER.

SELECT CAPE AND NEW HOLLAND PLANTS. No. 3.

RORLLA.

THIS is a small genus of plants belonging to the Campanulacese, the chief characteristic being derived from the capsule,

which is elongated and two-celled, opening by a hole in the apex. The species here given is a somewhat delicate plant, and requires care and attention to grow it satisfactorily. As a proof of its beauty it still may be found in a great many private collections, and is well deserving the attention of all plant-growers. Pot in good fibry peat, adding about a third of sand; and it some pieces of sandstone or charcoal are introduced they will serve to keep the soil more open and greatly benefit the plant. Special care must be given to the drainage, not so much as regards quantity, as in the matter of covering in order to prevent the soil running into it and stopping the

free percolation of the water; for although the plants enjoy a liberal supply of water they cannot suffer the alightest stagnation, for when this comes about either at the roots or in the atmosphere its greatest bane, mildew, is sure to make its appearance. By no means stimulate the plants during winter, but have the growths well ripened in autumn, and the plants will pass through the dull season in good condition. The growths made in winter are always weak and miserable. A dry atmosphere with a free circulation of air are requisite for the health of the plants and the prevention of mildew.

the health of the plants and the prevention of mildew.

*Roella ciliata (fig. 33).—A slender-growing, much-brauched, greenhouse ahrub, attaining a height of some 2 or 3 feet.

*Leaves alternate, linear, erect, ciliated, Heath-like, and light.

green. Flowers terminal, easile, campanulate or funnel-shaped, with a five-lobed spreading limb. There are five distinct colours in the flowers, which, being disposed in rings or circles, produce a striking effect. The base of the corolla is yellowish white; succeeding this is a circle of deep bluish black; above this comes another circle of lavender blue succeeded by a narrow ring of white, whilst the spreading lobes are pale purple. It blooms during May, June, and July. Cape of Good Hope. 1774.

A genus of handsome-flowered shrubs belonging to the Daphne family (Thymelacese). The name refers to their peculiar fat or oily seeds. They are slender branching shrubs,

having dense capitate heads of flowers, which are surrounded by an involucre of leafy bracts, mostly terminal, or more rarely axillary. Like many other beautiful plants, Pimeleas if neglected grow lanky, lose their lower leaves, and become excesaively ugly; indeed we have seen plants which could be compared to nothing but scrubby brooms. In this state it requires a great deal of faith in an amateur to believe in their desira great deal of latter in an amazeur to believe in state ability for the ornamentation of the greenhouse, but when properly managed few plants give greater pleasure. To accomplish this the plants when some 2 to 3 inches high should be stopped; and the laterals when about the same length again and again must have their points pinched out, which will soon result in the formation of a handsome boshy plant. When this is accomplished and the plants arrive at a flowering stage the last stopping should take place about the middle or latter end of July, when, if the growths are properly ripened, every branch will be crowned with a head of bloom the following spring. After flowering the plants should be cut hard back, and the same attention paid them again in the matter of stopping. Pot in fibry peat and light sandy loam, in the propor-tion of three parts of the former to two of the latter, adding sufficient sand to make the whole feel gritty when taken in the hand. Pot moderately firm, drain well, and water liberally but carefully during summer. In winter care must be taken to water only when dry, but they must not be allowed to become sufficiently dry to suffer by want of moisture. A free circulation of air at all seasons is necessary for their well-being, and during the hottest weather in summer some slight protection from the sun will be found very beneficial.

Pimelea spectabilis.—A large-growing species of great beauty. Leaves opposite, linear oblong, smooth and light green. Flowers produced in large terminal heads; involuce alightly coloured; corolla pink and white. In the form called spectabilis roses the flowers are wholly deep rose. It blooms

spectabilis roses the flowers are wholly deep rose. It blooms during April and May. Swan River. 1840.

P. Nieppergiana.—A somewhat strong but very compact-growing species. Leaves oblong ovate, dense, and dark green. Flower heads terminal, large and pure white, produced during May and June. Swan River. 1846.

P. macrosephala.—This is a robust species, but very rarely to be met with in collections. Leaves opposite, broadly lance-late recommends account of lightly always and light covery.

olate, somewhat secund, slightly glaucous and light green. The beads of bloom are large and spreading; colour deep rose. It flowers during May and June. Swan River. 1848.

P. Hendersons.—A smaller-growing plant than either of the preceding. Branches slender. Leaves opposite, linear lance-olate, and bright dark green. Heads of flower terminal, crowded, rosy pink in colour. May and June. King George's Sound. 1837.

P. clegans.—This is a free and robust-growing species. Leaves opposite, broad, ovate lanceolate, about an inch long, and deep green. The heads of flower are large, globose, crowded, creamy white or straw colour. May and June. New Holland. P. diosmafolia.—Bears some resemblance to P. decussata.

It is, however, distinguished by its larger heads of bloom and the larger but less dense leaves. It is a free-branching plant, with oblong decussate bright green leaves. Heads of flower terminal, somewhat spreading, and warm rose colour. June and July. New Holland. 1826.

P. doussata.—A compact-growing species with decussate leaves, which are ovate, coriaceous, bright shining green above, paler below. Heads of flower dense and bright rosy pink in colour. May to July. New Holland. 1824.

This genus belongs to the same natural order as Pimelea, and the various members bear some resemblance to it. They are alender-growing Heath-like plants with capitate flowers. It includes many species, several of which are employed economically. Pot in two parts fibry peat, one of good light loam, and one of sand. For general treatment see Pimelea.

and one of sand. For general treatment see Pimelea. Guidia pinifolia.—A very handsome species. Leaves scattered, linear, obtuse, triangular, and light green. Flowers terminal, capitate, dense, creamy white, changing with age to a light yellow, very fragrant. It blooms usually during March and April, but if stopped late the previous summer the flowers will appear about May. Cape of Good Hope. 1768.

G. simplex.—This is not so fine a plant as the preceding; it is, however, well deserving general attention. Leaves linear, scute, bright green. Flowers produced in terminal umbels, pale yellow. It blooms during May and June. Cape of Good Hope. 1788.

Hope. 1786.

G. imberbis.—A pretty, compact-growing, and much-branched species. Leaves three-angled, linear acute, dark green. Flowers terminal, capitate, somewhat short, sulphur yellow, to which the red stamens afford a pleasing contrast. It blooms during May, June, and July. Cape of Good Hope. 1792.

GASTRONEMA SANGUINEUM.

A CORRESPONDENT, J. Wilson, asks us for some information relative to a plant he has received from South Africa under the

Fig. 34,-Gastroneine, sanguineum.

above name. We cannot better reply than by submitting the accompanying figure and description. It is a greenhouse bulb belonging to the Nat. ord. Amaryllids (Amaryllidacese), and to Hexandria Monogynia of the Linnean system.

A hollow glaucous stem, 4 or 5 inches high, supports a single sessile flower of its own length, surrounded at the base by a pair of long narrow spathes. The tube is slender and greenish, and expands into a deep rose obconical throat, having six crimson lines running from the sinuses of the limb on the outside, and on the inside as many white bands, each with a crimson streak along the middle. The limb is very deep rose colour, with six equal-spreading, oblong, whole-coloured segments. The leaves are nearly as tall as the flower, dark green, in a very small degree glane in a did gradually widen towards the end, which is blunt.

The bulb should be potted in rich sandy loam, and treated like Habranthus and similar bulbs. It is increased by offsets. It is very handsome, deserving general carrivation even in the most select collections. It was introduced from Caffraria in 1845.

POTATO MAGNUM BONUM.

In the spring of the present year I purchased 14 lbs. of Suttons' and 14 lbs. of Carter's Potatoes under the above name as trial samples. Not being an exhibitor I had no other object in view than to test the respective qualities of the two varieties, or rather a Potato which I suppose was originally the same. On the 4th of April I planted them side by side on a piece of ground that had been for years a Globe Artichoke bed, two rows of Suttons' Magnum Benum and two rows of Carter's Improved Magnum Bonum, all 3 feet apart between the rows and I foot from set to set leaving a clear margin on both outsides of about 34 feet. Every Potato grew, but when they fairly started a few inches out of the ground I noticed that Suttons' intended to take the lead in the race, which they did, and for several weeks before the growing season was over they were from 8 to 10 inches higher than Carter's, and continued the lead till the end of the season. The stems also showed a more robust habit, and at the end of the season held out a fortnight longer than did Carter's. On the 15th of September I lifted them, feeling rather anxious to ascertain if there was any difference in the two samples in size or general bulk. Produce: Suttons' 14 fbs. gave 210 fbs. of good healthy tubers and six diseased tubers; Carter's gave 175 ibs. of good tubers and fourteen diseased tubers. Suttons' uniformly being throughout the sample a trifle larger than Carter's. I can discover no difference in the shape of the Potatoes, but the question may arise whether the difference in growth constitutes them distinct varieties. Suttons' has with me proved the heaviest cropper and the most perfect disease-resister I have grown this season .- H. W. WARREN, Hurstbourne Park Gardens.

AMPELOPSIS VEITCHII AT FROGMORE.

Not many plants introduced to our country during the past twenty years have proved so useful and have maintained their popularity so well as has this now familiar and beautiful climber. Its easy culture and its adaptability to various positions in town and country have rendered it a general favourite. When seen in its full autumnal brilliancy the effect is irresistible, and after admiring a well-coloured specimen the next and almost inevitable step is for the spectator to possess a wall plant so accommodating and so strikingly attractive; and so the plant spreads until the demand for it now is greater than ever, which is the highest possible testimony of the value of a plant which, under the name of A. tricuspidata, was first placed before the public by Messrs. Veitch in 1868. The plant, however, is now known as A. Veitchii, and will continue so to be known for generations to come, and certainly no plant can better commemorate the name of its introducer than this firmly established and widely cultivated climber from Japan.

Ampelopsis Veitchii now adorns many a villa and even cottage garden, droops in gorgeous drapery over many a rockery in palatial establishments, and is now the most conspicuously brilliant object in the Royal Gardens. As covering a number of large pillars and buttresses at the entrance of Her Majesty's kitchen garden and spreading on the adjacent offices it is now, when seen under the advantages of a bright day, simply magnificent—a glowing mass of metallic lustre of chocolate, crimson, and scarlet, which no flowers in the garden can equal.

The examples, too, at Frogmore are instructive as well as attractive, for there are several plants growing on different aspects, produced by the sharp curve of the wall—almost a half circle. The foliage is the most brilliant where it is exposed to the sun—west and south-west, the plants simply growing in the gravel walk. The leaves are much smaller and comparatively dull where the wall is shaded—facing northwards, and where the plants are growing in a cold damp border. The plant, then, requires a warm dry soil and sunny position to bring out its full beauty.

One pillar is much more heavily clothed than the others, the leaves of the two plants covering it being very large, 5 or

6 inches in diameter, only slightly lobed and intensely dark and shining, but not so fiery in appearance as those of the adjoining plants. The striking difference referred to hasging rise to some debate on the spot as to whether there are two varieties or whether the dissimilarity, which no one can fail is notice, is due to "something in the soil." It seems singler that the soil at the base of one pillar of the entrance give should be so far different from that around the opposite plants as to cause a difference in growth so manifest; but then, agin, it is about equally singular that the only two plants having the larger and darker foliage should, out of about twenty, happen to have been planted together. The dissimilarity of foliage certainly most marked, but it is something to know that the examples of growth are equally imposing, the one by the large and dark foliage, the other by the smaller and brighter leave.

Wherever a suitable position can be found for Ampelopsi Veitchii there a plant should be grown; it will ding to say building to which any other plant will adhere, and with a minimum amount of trouble will produce a brilliant man of colour during the autumn months. The Frogmore plants have been "in colour" for upwards of a month.

FRENCH NOTES.—No. 3. BOURG-LA-REINE, SCEAUX, &c.

IF the condition of my poor friend M. Souchet addend my visit to Fontainebleau, that of my friend M. Margottin was calculated to make me feel just the reverse. Our aquaintage dates from the same period, and since that time I have never but once visited Paris without paying him a visit. I will not say that he has not altered since that time, but it was a real pleasure to see how hearty and genial he is; and he has gone through something, too, since then. The Badois, a very indifferent (as far as conduct and manners go) contingent of the German army, occupied Bourg-la-Reine during the sept. They took possession of my good friend's house. They did worse—they destroyed it, tore up the staircase for freewood, damaged all the furniture, and left it in such a condition that he did not care to live there again. He and his family retired to Paris, to come back after the city was taken and to find desolation where he had left all in order. Well, like a have man he has struggled through it all. He has built himself a new house; has seen his son, good young Jules, married, and his grandchildren growing up around him. But it is a sal index of the uncertainty that still hangs over France, that when I said to Madame Margottin, speaking of their treaks in the war, that "It is all over now, I hope;" "Pour dir sa, monsieur," ten years being in her estimate the extent of their tranquillity. Arthur Turner, the worthy son of a worthy sir, met me at the station in Paris at ten o'clock. We had promised to take our breakfast with Jules at twelve o'clock, and visited his father's nursery first. Here a hearly welcome awaited us, and a fine Cantaloupe Melon and some capital specimens of Bon Chretien Pear provided for our breakfast. It is a curious fact as indicating the difference of tasts of the transfer of the company of the com two countries, that this Cantaloupe Melon is preferred to the more highly flavoured varieties which we grow. M. Margtin had a good collection of these in frames, and yet note of them find so much favour as the thick-skinned rough-looking (antiloupe. That it should be grown as a hardy sort I can quite understand, but do not equally so the taste; and why is a like of Melon considered indispensable in the early part of a dimer or dejedner? In looking round the garden we were struck with a pretty little climbing Strawberry with bright red fruit and yellow flowers, the first worthless for eating but quite one mental; and as the foliage is small it makes a very peth little climber for a pot. What is it? The only yellow showed Fragaria that I can find any note of is Fragaria indica: can it be that? be that? The Roses looked well and the buds had taken By-the-by, M. Margottin told us that he does not us either cotton or bast for tying-in the buds, but rushes. There are us in any of the distance of the distan in any of the ditches, dried, and then before being und dipped in water; the bud is tied in, and by the time that it has begun to swell the rush decays, and so all the trouble of going round and untying is done and so all the trouble of going round and untying is done away with. It has thus a great admined over the ordinary over the ordinary tying materials. It is to be pround I believe, in Paris, and is very cheap. If I recollect rightly half a franc's worth would suffice for a thousand plants. I found that as a rule the France's worth would suffice for a thousand plants. that as a rule the French growers insert three buds in a state that as a rule the French growers insert three buds in a state that as a rule the French growers insert three buds in a state of the stat dard, thus securing a fine head. Amongst minor thing L.
Margottin pointed and head. Margottin pointed out to us a very excellent French Best. Précoce de Temple, especially good for Haricots, a regentle

winter use, but not nearly so much as it ought to be.

In M. Jules Margottin's garden we saw a Grape of which he spoke very highly, but which I do not find in the "Fruit Manual," and which therefore I conclude is but little known. He called it Gradisha, and said he believed it was Hungarian. It is somewhat like Chasselas de Fontainebleau, which is so great a favourite with French people, but more transparent, not the same beautiful tinge, and of excellent flavour and very free-bearing. His Vines are uncommonly well managed, and those for fruiting in pots were excellent. His stock of Roses was admirable, and I do not ever remember to have seen a more splendid piece of standards than those he showed us; the stems were beautifully straight and the heads exceedingly fine. He had along his wall Maréchal Niel growing most vigorously, and adopted a plan which might be, I think, successfully imitated here—vis., placing over them in the spring some spare lights the shell with the straight of the lights, thus sheltering them from the weather, giving them a chance of coming in a little earlier, when the buds are in as great demand as with us; and then when the flowering is over, the lights being taken off, the plants become more hardy than when grown in the house. Besides, the economy of space is a great matter. He had some good Roses in pots for exhibition, but not like those exhibited by our great growers Mesers. Paul and Son, and Turner; nor were they treated in the same way, for they had been out of doors plunged since they had bloomed. Of course, like all Rose-growers, our young friend is anxious to have his name connected with some good Roses. Boieldies sent out by him is a good variety, and he has now one (not to be let out this season) on which he builds much hope—a pure white Gloire de Dijon. We saw it in the bud state, and it certainly bore out the character. It is not, I believe, a sport, but has apparently from its wood some Souvenir de la Malmaison in it.

He has an ingenious plan for preparing his Briar stock for planting. A sort of cutter, something in its manner of using planting. A sort or cutter, sometiming in to maintain the like a chaff-cutter. One is large and strong; into this he places the root, one man doing it. With the left hand he holds the Briar and then pares off the roots, making the knob perfectly smooth; it is then passed over to another man, who cuts the strong of the strong of the left strong and with an implethe stem either for a standard or half-standard with an implement of the same character, only not quite so strong. The cut

is very clean, and it is very expeditiously done.

After partaking of his hospitality we went to Sceaux, and taking a fiacre paid a visit to Messrs. Thibaut & Keteleer's two nuseums. The last time, now many years ago, that I had the pleasure of seeing them was at the Rue de la Roquette in company with the late John Standish. Since then they had, like many others, gone through much. Their establishment at Sceaux had been completely destroyed during the war, and it has required a great deal of perseverance and money to recover their garden. It is the only establishment in the neighbourhood of Paris that at all approaches our great London firms of Veitch, Bull, Williams, Henderson, and others, but even it falls very far short of them in magnitude and value of its contents; but there is always sure to be something interesting.

The Tuberous-rooted Begonias form an interesting feature here, and certainly some of the finest and most distinct that I have seen are here. One particularly struck us, a yet unnamed seedling (No. 9), intense deep scarlet and very large. Each petal measured more than 2 inches, and the whole appearance of the plant was remarkable : in fact as we walked through I saw hundreds of plants in bloom. We came back to No. 9 as the best. There was also another remarkable novelty; the petals were French white, and two of them distinctly margined with pink; while of those sent out last year Le Géant, a very fine vigorous grower with deep velvety crimson flowers, was very fine. However, it is, I think, not unlikely that the desire to possess named varieties will diminish, for here we saw good—nay, even large flowering plants from seed which had been sown in March; and where good seed can be had one is sure to obtain some, if not quite, yet nearly, as good as named varieties. It is thus that the Cineraria and Calceolaria have come to be grown. How few ever think of asking for named varieties! Good seed is obtained, and the result is a fine display of vigorous growing plants. There was also a very large collection of Zonal and other Pelargoniums. M. Keteleer premised of the double white that Candidissima and Mont Blanc were still the best, while I could see that the French-raised Pelargoniums were preferred to the English varieties, those of Boucharlat, Alegatiere, and Lemoine being most numerously grown. There was a very curious little—in fact miniature-

which is beginning to be more appreciated amongst us for | Ivy-leaf Geranium, very small, and excellent for a climbing pot plant.

There were also in the garden very many interesting subjects. I found both here and at Fontainebleau the Bamboo flourishing, and yet we cannot grow it in England. Why is this? The temperature of Paris and its neighbourhood is considerably lower in winter than with us, and their frosts are much more severe. M. Keteleer mentioned that the variety called Queloi is the hardiest, and I hardly see why in sheltered places it should not do. I know that in the south of Ireland and Cornwall it succeeds, but I believe that even there it succumbs in some winters.

In a small enclosed space M. Keteleer had what he called his own garden, containing choice specimens of some of the rarer kinds of Conifers—Abies, Retinosporas, Thujopsis, &c. Of these he seemed, and justly so, very proud, as doubtless in the lower temperature of Paris there must be a greater difficulty in growing them than with us. The collections of Delphiniums, Phloxes, &c., were also very good, although I did

not observe anything particularly novel amongst them.

The whole neighbourhood is very pretty, undulating, and well wooded, while nurseries abound, that of M. Croux being one of the most extensive fruit tree nurseries in the neighbourhood of Paris, and his trees most wonderfully trained; and we were particularly struck with the quite open character of the various grounds, so that, as my companion quietly observed, it must be rather a difficulty in executing an order to know quite where the division between the grounds existed. Even if one had no horticultural tastes all the surroundings here are well worth a visit, but to those who have there is no greater treat in the neighbourhood of Paris than that which I have thus briefly sketched.—D., Deal.

SHEFFIELD, ITS GARDENS AND GARDENERS.

SMRFFIELD is well known as one of the most important towns of the kingdom, but its gardens and gardeners are but little heard of beyond the district known as Hallamshire. The leading gentry are wealthy and liberal, as the various edifices erected by private munificence for the public benefit churches, schools, institutes, almshouses, libraries, &c.—testify; but they have not, as a body, entered in any spirited manner into the delightful pursuit of horticulture. Travellers passing across the town by rail, and knowing little more of it than the flying glance affords them, may naturally conclude that the nature of the trade of the place and its accompanying smoke are insurmountable impediments to the successful culture of plants and fruit within a reasonable radius of the reeking valley below, for Sheffield is in a valley nearly surrounded by hills. But cross this busy valley and ascend the hills, and even before the outskirts of the town are reached gardens may be found well worthy of the name—gardens not large, but as clearly cherished as they are obviously well managed. Continue to ascend, and imposing mansions are seen surrounded by grounds more or less extensive, and a district highly picturesque—deep and well-wooded dales and bold hills producing such a contrast with the scene below as is probably not to be equalled in the kingdom. It is on the higher ground of Sheffield that gardening is conducted—where men, skilful and industrious, well maintain the credit of the craft; where plants are grown worthy of any exhibition, where Orchids are cultivated in a manner rarely surpassed, where fruit is produced of the highest order of merit, and where florists' flowers are raised of the first order of excellence.

Such is Sheffield and its gardens. Its gardeners are emphatically men of action, for in no district with which I am acquainted is a greater amount of work done in a better manner than is to be seen in the gardens at Hallamshire: They work, too, in comparative obscurity, there being no great horticultural exhibitions to afford public expressions of their skill and to stimulate them to further efforts. Local shows there are—perhaps too many, but no central society which the town and district could so well support. Yet the gardeners are conscious of the necessity of mutual aid and friendly co-operation, hence have established an Improvement Association, for the sole purpose of making them better gardeners, better servants, and better men. By the reading of papers and discussions thereon, and by giving such aid as they can afford in cases of misfortune or temporary distress that may befall any member of the body, they are engaged in a work that is unquestionably good and worthy of countenance and support.

They, too, have occasional shows; and here again it is note-

worthy to observe that they exhibit for honour and not for gain. At the Chrysanthemum show, for instance, to be held in November no money prizes are provided for the members, but only certificates of merit; but in order to bring to their midst superior examples of culture, and to provide a higher standard of excellence to which they hope to attain, they provide a silver cup and money prizes to be competed for by cultivators in any part of the country, subject to the payment of a small entrance fee, which is usual and proper under such circumstances. The arrangement referred to is proof of the earnestness—the real gardening spirit—that animates the cultivators of this district and their section it much be desirable. tivators of this district, and their action, it must be admitted, contrasts favourably with the mere money-hunting exhibitors who support shows mainly for what they can get out of them. "Big prizes," says a florist of great experience and high reputation, one whom to know is to esteem—Mr. B. Simonite— "have done more than anything else to banish that true earnest love for flowers that real florists feel, and have led to temptation and questionable tactics in exhibiting that are closely akin to mere speculation." A different spirit prevails about Sheffield. The object desired is self improvement, and not a mere acquisition of money, and their endeavours there-fore merit support and deserve success.

Very briefly in a future issue some of the Hallamshire

gardens shall be more particularly referred to.—J. W.

ASCLEPIAS CURASSAVICA.

THIS species is one of the most attractive of the peculiar and interesting genus Asclepias, and its bright flowers very pleasantly enliven the appearance of a stove or intermediate house at the present time. As the cultivation of the plant is by no means difficult and the flowers are produced freely, it is not surprising that it should have early received the attention of cultivators; but even now, although introduced in 1818, it is not nearly so generally grown as it deserves. This is a South American species, and it bears numerous umbels of flowers the petals of which are reflexed and deep orange in colour, while the small cup-like appendages that form the stammal corona are bright yellow. The contrast is a very pleasing one, and the brightness of the colours is relieved by the dark green simple leaves that clothe the stems. There is also a white-flowered variety that is well adapted for a companion to the ordinary form.

In the treatment of these plants no especial skill is requisite, and few plants, considering the little attention they demand, produce more gratifying results. Propagation may be effected by cuttings, seeds, or division of the plants, but the former method of increase is the most satisfactory. Cuttings should be prepared in the usual way early in spring and inserted in light sandy soil, the pots being placed in an ordinary propagating frame. When the cuttings are well rooted they should be carefully turned out of their pots and separated, injuring the young tender roots as little as possible. They may then be placed in 60-sized pots, employing a compost of local well decomposed may be a second may be seen to be see loam, well-decayed manure, peat or leaf soil, and sand. As they fill the pots with roots shift the plants into larger pots and place them in the stove, supplying water freely. Flowers will be produced the first season, and a stock of these small plants is always useful for decorative purposes. As the plants go out of flower late in autumn remove them to a cool position, partially withholding water during the winter. In March, turn the plants out of their old pots and remove some of the soil from their roots, reporting in the compost previously recommended. To obtain a succession pot batches of plants in March April and May and by this means a maple of flower. March, April, and May, and by this means a supply of flowering plants can be maintained from June till October.—L. C.

NOTES ON VILLA AND SUBURBAN GARDENING.

BEDDING plants in most gardens are now being removed. The cold foggy nights give a warning that it is not safe to risk any tender plants out after this. As they are lifted they must be potted in small pots and stored away pretty thickly together under glass. The lowermost leaves of Pelargoniums should be removed at the time of potting; but do not cut the plants back now, as it causes the majority to damp and speedily decay. By allowing the tops to remain they will furnish in the early spring a good supply of strong cuttings, which when taken off will cause the old plants to break quickly and make dwarf and stocky plants.

CALCEOLARIAS AND GAZANIAS.—Cuttings of these plants will strike readily now if inserted in a sandy soil in cold frames, and

possibly make better summer plants than those taken some time ago. Echeverias and Sempervivums that are not sufficiently hardy to endure the winter should be lifted and packed away closely in boxes, &c., damp being one of their greatest enemies; they require protection as much from rain as from frost. We have preserved numbers of these by merely making a raised bank against a dry wall, and planting the succulents thickly thereon; a coping of boards threw off the rains, and a covering of mats protected the plants in frosty weather.

CHRYSANTHEMUMS.—It is not safe to allow these to remain out of doors any longer, but be particular not to confine them in a close atmosphere, or mildew will set in and the foliage will speedily decay. Continue to supply them with liquid manure now that the flower buds are fast swelling, but discontinue the use of it as the flowers expand. Train the growths of plants intended for specimens, and disbud all after growths as they appear. If there is specimens, and disbud all after growths as they appear. If there is any aphides fumigate as soon as possible, otherwise these insects will injure the flower buds, and if mildew spreads keep it under by frequent applications of sulphur. In the case of plants intended for exhibition, and if the structures for housing them are low and small, it is a very good plan to remove the stakes and secure the plants to the rafters near the glass; they will in this way produce large and full flowers. Dahlias are as yet blooming profusely; as soon as the leaves are killed by frost cut off the stems near the ground, dig the tubers up carefully, and place them under cover to well dry before storing them safely away in their winter quarters.

quarters.

Window Boxes.—These will now require renovating, the summer occupants being entirely removed, substituting in their places plants of a hardier constitution, and for this purpose there is nothing to surpass many of our hardy and elegant shrubs, such as Ivies, Aucuba, Box, Euonymuses, Arbor Vites, Junipers, Betinospora, Cryptomerias, Cupressuses, &c. Small plants of any of these are so graceful and give such a cheerful appearance during the dark dull days of winter, and can be purchased so cheaply, that no windows in populous towns should be without them. They are not particular to soil, and will endure much rough usage, but when left in small pots exposed to extreme frost they cannot but be expected to finally perish.

WORK FOR THE WEEK.

KITCHEN GARDEN.

CLEAR the quarters of exhausted crops, and manure, dig, or trench the ground as may be necessary. Deep cultivation is essential to the production of profitable crops of high class vegetables. The shallow surface soil of most vegetable gardens. vegetables. The shallow surrace soil of most vegetable gardens is, from the frequent heavy manuring and continuous cropping, full of decaying matter, which encourages a gross growth in the young plants that is not sustained when they are approaching maturity; hence they succumb to drought, and do not afford nearly so good a return for the manure applied as in soils loosened to a greater depth. Trenching should be practised loosened to a greater depth. Trenching should be practised every second or third year, turning the top spit to the bottom, and bringing the bottom to the surface. The soil brought up should be distributed as roughly as possible, and when the ground is dry with frost manure may be applied. It may lie on the surface through the winter, and be forked in during favourable weather in early spring or late winter. Sandy soils are not nearly so much benefited by digging or trenching and exposing to the influence of the atmosphere in winter as those of a strong or claver nature, and exposure to the air only hastons the decomposition. clayey nature, and exposure to the air only hastens the decompoclayer nature, and exposure to the air only hastens the decomposition of those substances to which they owe their fertility. Pror to turning up for the winter most soils will be benefited by an application of lime at the rate of about eighty bushels per acre. Such, soils will also be permanently improved by a dressing of clay or marl; twenty cartloads per acre is a good dressing, spreading it on the surface and allowing it to be disintegrated by exposure to frost before digging it in. Old gardens are often advantageously improved by the addition of fresh loam, and if turty it will prove most effectual. The main crops of Carrots, Beet, Salsafv, and Scorgonera should be taken up on a dry day, and be will prove most effectual. The main crops of Carrots, Beet, Salsary, and Scorzonera should be taken up on a dry day, and be placed in a dry siry shed to become moderately dried before storing away. In lifting and trimming Beets care must be taken not to injure the roots, or the colour will suffer. Store them away in sand in a cool shed or cellar. Complete the planting-out of Lettuce plants to stand the winter, and the principal crop of Cabbages must not be delayed in planting. Any surplus Calli-Lettuce plants to stand the winter, and the principal crop of Cabbages must not be delayed in planting. Any surplus Canliflower plants not required for planting in frames or under handlights should be pricked off near a wall with a south aspect, where they will endure an ordinary winter, and if planted out in spring form a succession to those from handglasses. Canliflowers coming into use will require attention in the case of sudden frosts, breaking a few of the leaves down over those more advanced, which keeps the heads clean and white; but in case of severe frosts the plants should be lifted and laid in pits, can be given. Crops that are to stand the &c., where protection can be given. Crops that are to stand the winter should be kept free from weeds, and be thinned so as to induce a sturdy habit. Lettuces and Endive ready for lifting should be planted in frames, and with ordinary regard to ventila-

Beans in pots, employing moderately light rich soil. If a sowing were made in low pits or houses for a late crop the plants will require attention to prevent their damping-off, and should have a temperature of 65° to 75° by day, and 55° to 60° at night. Periodical sowings of Mustard and Cress will be necessary to maintain the supply.

HARDY FRUIT GARDEN. Where necessary, preparations may now be made for lifting or root-pruning, operations that are best performed before the leaves fall, as their presence is necessary to induce the formation of fresh rootlets before winter. There is danger, however, in commencing operations too soon, as with sappy immature wood too great a deprivation of roots will cause the comparatively young leaves and wood to shrivel. In lifting trees that have filled their as the roots are found, 6 to 8 feet from the bole of the tree, carefully forking out the soil so as not to injure the roots, which must be replaced in fresh soil. In making or renovating fruit-tree borders a little extra attention at first would often save much after labour and outlay. Some plant trees without any regard to the character of soil and the necessity of drainage. All borders should be efficiently drained if necessary, and for wall trees the bottom of the border should have a good fall from the wall to the front, and have a foot thickness of brickbats or rubble placed under the soil, and to keep it open be covered with turves or litter of some kind. The depth of the border should be 2 feet, and turfy loam taken off with its turf 4 to 6 inches thick will suit most fruit trees without any addition. If of a heavy or retentive nature it will be improved by the addition of charred refuse, road scrapings, and old mortar rubbish, whilst if light an addition of mari and burned clay will prove beneficial. The planting of fruit trees should be performed as soon as the leaves have fallen, or if they are on the spot they may be transferred to their new positions when showing indications of falling. In preparing sites for new plantations of Currants, Gooseberries, Raspberries, &c., drainage must first be attended to, and the ground then trenched and well manured. Remove all useless shoots from every description of fruit tree, bringing to a close summer pruning and nailing. Do not hurry-in the gathering of autumn Pears and Apples. Have the fruit-room thoroughly cleaned, the walls limewashed, the shelves, &c., well scoured, keeping it cool, dry, and well ventilated.

Cucumbers.—Place out at once the plants for fruiting in winter on hillocks or ridges as near to the glass as the nature of the house and trellis will permit. Those not having the convenience of a Cucumber house may obtain supplies of fruit by growing the plants in pots or boxes in Pine stoves or other sufficiently heated plants in pots or boxes in rine stoves or other summently neared structures. Let the autumn-fruiting plants be regularly looked over once a week, removing any bad leaves and exhausted growths, training in young growth, pinching out the point of the shoots a joint or two beyond the fruit, avoiding overcropping and overcrowding, and removing male blossoms. Keep the temperature at 70° by night and 75° by day, advancing to 80° or 85° with sun heat, admitting a little air whenever the external air is favourable. Keep the glass clean, as every ray of light is now of consequence. Moderate the supply of water at the roots, not, however, permitting flagging. Melons.-

FRUIT HOUSES.

Melons.—The Melon season as regards dung-heated pits and frames may now be considered at an end. Any fruits yet remaining and fully grown may be cut and placed in a warm house to ripen. The latest plants in houses will require a night temperature of 70° and 75° by day by artificial means, advancing to 85° with sun heat, admitting a little air at every favourable opportunity. Sprintling the next season will be recessive about 5° to the face wil with sun heat, admitting a little air at every favourable opportunity. Sprinkling the paths, &c., will be necessary about \$ A.M. and \$ P.M., until the fruit is full grown, when a drier atmosphere will be advisable. Cut out all superfluous laterals, well thinning out the old foliage, so that the fruit may have the full benefit of the autumn sun. Before the ground is soaked by rains secure the required quantity of compost for next year's crop—rather strong loam taken off with its turf, stacking it grass side downwards, adding about a basel of cricklims to each cartlond in stacking it adding about a bushel of quicklime to each cartload in stacking it.

It will be in capital condition by spring.

Pines.—All young plants should now be arranged so as to obtain the fullest benefit of light and air. As the sun heat diminishes a corresponding diminution of temperature should take place at night, until it reaches the winter standard of 55° to 60° at night and 65° at night and in the daytime. Ventilate freely whenever external conditions are favourable, paying particular attention to watering. An inspection of the plants should be made about once a week, and whenever a plant needs water supply it copiously at about the tem-perature of the bed. Plants on which fruit is now appearing will be ripe at a time when other fruits are scarce, and should therefore as the minimum temperature in the fruiting house. Continue 70° as the minimum temperature in the fruiting house, though on cold nights a decline of 5° may be allowed, and 5° more in mild weather—75° artificially by day and 80° to 90° from sun, closing the house at 85°, sprinkling as may be necessary the pathways

tion and protection they will keep in good condition for a long time.

Forcing Department.— Make successional sowings of French**

**The department of the protection of t

Strawberries in Pots.—The autumn and winter fruiting plants Strawberries in Pots.—The autumn and winter fruiting plants must without further delay be placed under glass and on shelves, so that they may enjoy a free circulation of air, ventilating so as to dispel damp, as the fertilisation of the blossom is not satisfactorily effected in a moist atmosphere. Those swelling and ripening the fruit in frames should have air moderately, and though the first will swell and ripen in cold frames they swell better and the flavour is enhanced in a house where there is a moderate. the flavour is enhanced in a house where there is a moderate degree of heat—50° to 55° as a minimum and 70° to 75° as a maximum by artificial means. Plants for next year's fruiting are late; they are neither so strong nor the crowns so well matured as they should be at this time of year. Those intended for early forcing should be placed on a bottom impervious to worms in frames or cold pits, exposing them fully to every gleam of sun, employing the lights only to ward off heavy rains and at night. The remaining plants should be kept in a sunny situation, as they will require every ray of sun to enable them to mature the crowns properly.

PLANT HOUSES. Greenhouse.—Solanums, though not impatient of a few degrees of frost, should now be taken inside, and be assigned light airy positions. Those from the borders that have been potted will now have rooted, and must be well supplied with water or the leaves will turn yellow. See that the plants are free from aphides, otherwise the appearance of the plants will be spoiled. If plants are required early they may be forwarded by placing them in gentle heat when the berries commence colouring. Roches falcata when out of bloom should have the main stem cut back, removing the leaves singly from the stem with a sharp knife, and insert them singly in sandy soil in small pots near the glass. This is one of the most useful of autumn-flowering plants. Few plants are more brilliant than Clianthus Dampieri; but it, too, is not common. It is impatient of damp, and cold cutting winds not only check its growth but induce attacks of red spider. To grow only check its growth but induce attacks of red spider. To grow it well a temperature slightly higher than an ordinary greenhouse is necessary with a position near the glass, avoiding overwatering, whilst allowing it to flag is equally injurious. The roots should be disturbed as little as possible, transferring from the seedling pot to the one in which they are to bloom at once. A 9-inch pot will contain a good specimen. Any plants in small pots should be transferred to a larger size with the ball entire, not removing the crocks, draining efficiently, and employing fibrous peat but sandy, with about a sixth of charcoal. The plants evidently dislike having the shoots trained upright, as after the first erect like having the shoots trained upright, as after the first erect growth is somewhat advanced it emits other shoots from the base, which invariably take a horizontal course. Salvias require a little extra heat to enable them to develope their flowers, 50° at night being sufficient, affording weak liquid manure and a light position. The bright scarlet flowers of these enliven other plants wonderfully at this season. Primulas should now be placed in dry, airy, and light positions, or the plants will damp off. Supply plants advanced for flowering with weak liquid manure. Cinerarias delight in a rather moist atmosphere and a cool damp bottom, having plenty of room and light. Liliums as the growth matures should be repotted, removing all the small bulbs that are formed on the stem, potting those several together in small pots. A considerable portion of the roots of Liliums die annually, there-A considerable portion of the roots of Liliums die annually, therefore in repotting it will be necessary to preserve the live roots as much as possible, removing the old soil. The pots must be well drained. Good fibrous loam is well suited to Liliums; or if the loam is not yellow and fibrous, a third part of fibrous peat may be added, and a sixth to an eighth of old manure previously dried. They should be potted rather firmly and so as to admit of 2 to 3 inches of the dressing. Pleas them during the winter in of 2 to 8 inches of top-dressing. Place them during the winter in a pit or greenhouse from which frost only is excluded, or they may be buried 6 inches deep in ashes in a sheltered position outdoors, taking care to remove them before growth is much advanced. During winter they should only have water to keep the soil moist.

soil moist.

Heaths that were potted last month will have the roots growing freely in the fresh material, and as it is next to impossible to tell when they require water by rapping the pots they must be examined carefully, and afford supplies as may be necessary. Ventilate day and night in favourable weather. The plants are all the better for being kept as cool as possible. The and otherwise attend to the plants are the old dead foliage from the all the better for being kept as cool as possible. The and otherwise attend to the plants, removing the old dead foliage from the wood and surface of the soil, inserting the new stacks in the places the old ones have been removed from, so as to cause as little damage to the roots as possible. Seek to equalise the growth as much as possible, and to clothe the plant down to the growth as much as possible, and to clothe the plant down to the surface of the pot, for a bare specimen is not presentable in a collection of well-grown plants. Winter-flowering Heaths coming into bloom should have light airy positions, and not be overcrowded. Azaleas of the early flowering varieties alluded to in a former calendar should be placed in a house with a gentle heat so as to facilitate their flowering. The old A. vittata, so seldom seen, will flower for months, early plants flowering naturally at this season. The general stock should be examined for thrips,

washing with tobacco water any plants infested, thoroughly wetting the under side of the leaves as well as their upper surfaces and the wood, leaving the solution to dry on, which will destroy the insects and their eggs.

TO CORRESPONDENTS.

*** All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

BOOKS (Mag).—Brown's "Planters' Guide" contains all you mention (Selltri).—We do not know of any book such as you appear to require.

Many designs for gardens have been published in our pages.

GAB-TAR WALKS (A. II.).—If the tar is boiled, and after being spread on the walks is covered with lime rubbish, it hardens, and the rubbish being removed a surfacing of fine gravel can be applied.

DIONEA MUSCIPULA (Educard Wilson).—The leaf you sent is no doubt suffering from a surfet of nitrogenous food. The spider being rather bulky the vessels of the leaf became charged with the decomposed matter, and assimilation not being sufficiently rapid decay of the tissues of the leaf was induced. Perhaps also your plants are not in a very vigorous condition.

Induced. Perhaps also your plants are not in a very vigorous condition.

PLANTING POTATOES IN AUTUMN (G. S.).—We have adopted autumn planting with good results, but the soil was light and the site well drained. In ordinary heavy soils spring planting is preferable. The ground being this year so cold and wet your safer plan will be to defer planting until spring. If the soil is light and of a dry nature plant early, say during fine weather about the middle of February, the sets being placed 4 or 5 inches deep; but if the land is wet and strong April planting is preferable, covering the sets not more than 3 inches with well-pulverised soil. Had you stated the nature of the soil and the varieties employed we should have been better able to have stated the cause of your failure.

CAMPANULA ISODENTIA (A Content Parket)

anis to have stated the cause of your minute.

CAMPANULA ISOPHYLIA (A Constant Reader).—Although the species referred to by "J. B. B.," and figured on page 233, was named by the authorities at Kew as C. isophylla we doubt if that is the correct name of the plant. We have grown the plant as C. garganica, the name by which it is known, we believe, in the Cambridge Botanic Garden. We also saw it recently in the Sheffield Botanic Garden, and Mr. Hwing, the experienced curator there, considers the true name of the plant to be C. garganica. It is increased by division or cuttings, and you are not likely to obtain seed.

ADDRESS (M. E. H.).—If you write to Mesers. Biddles & Co., Loughborough, you will probably obtain the information you require.

HEATING A SMALLY CONSERVATORY (E. T.).—A percleum stove will not keep out severe frost. A small Arnott or any simple form of portable stove would answer for so small a building if you can contrive to carry the smoke pipe outside without its being a nuisance.

OLD WALL ROSE BARE AT BOTTOM (Idem).—Unfasten all the upper branches, and bend them down below the point where you require new growth, which will then push forth out of the bare old branches readily enough, and when it is a few feet in length the upper branches may be cut off without risk.

SHREDS AND NAILS versus a TRELLIS FOR PEACH WALL (A. C.)—Let the condition of the old stone wall which you intend covering with glass be your guide. If the mortar is much broken and has many holes it ought certainly to be pointed—not merely for appearance, but from its tendency to harbour insects; and we would strain wires 6 inches apart along the wall and secure them with staples—not only to preserve the wall intact, but because the training can be done much quicker by tying than by nailing, and it is certainly more economical. The front trellis for Figs should be of iron or strained wire, 14 inches from the glass and 6 feet high. Brown Turkey and Grizzly Bourgasotte are the two best Figs for a small house.

Theatment of an Old Shuringery (Old James)—Unless you receive SHREDS AND NAILS versus A TRELLIS FOR PRACH WALL (A. C.

TREATMENT OF AN OLD SHRUBBERY (Old Lawri).—Unless you require the space for other shrubs do not remove one of the old Laurels, but cut them down forthwith close to the ground, and they will make such vigorous tnem down fortunith case to the ground, and they will make such vigorous growth as to become handsome specimens in a couple of years, infinitely superior to any you could plant. We have so treated several old shrubberies of both Portuguese and common Laurels with invariable success. Any new shrubs you require may be procured and planted at once.

shrubs you require may be procured and planted at oldes.

TUBEROSEE UNHEALITY (Clifton).—We fear the plants grown from bulbs potted last spring, and which are now only 6 inches high, will do little good either this year or next. All you can do is to place them in a warmer house, where they can have a temperature of not less than 60° at night; the greenhouse is too cold for them. The size of pots requisite for growing Lilium auratum depends entirely on the size of the bulbs. As a rule pots twice the diameter of the bulbs will, with good cultivation, produce fire flowering plants. duce fine flowering plants.

BEGORIA FREEBELLI WITHERING (H. H., Oros).—If the roots of the plants are in an active state we can only attribute the shrivelling of the foliage and the dropping of the flowers to a too dry atmosphere and low temperature that have prevailed in many greenhouses during the past week or two. We saw plants similar to yours in an airy greenhouse the other day, while other plants from the same batch in a closer and warmer intermediate home were quite healthy, and continued to flower freely.

WINTERING TUBEROUS BEGONIAS (W. A. B.).—They may be preserved in a greenhouse where the temperature is not lower than 45°, but the soil in the pots must not be allowed to become dust dry, or many of the tubers will fail to grow in the spring. If you can plunge the pots in cocca-nut fibre refuse or ashes, and keep the plunging material moist, it will not be necessary to water the soil in which the tubers are resting. Even with the

best care the tubers of some varieties not infrequently refuse to grow in the

spring.

STRIKING BRIAR CUTTINGS (F. G. Oliver).—You will succeed by the mode you describe of selecting clean firm cuttings a foot long, and divesting them of all but two or three eyes at the top, and inserting firmly in ridges. The ridges should be 18 inches apart, and the cuttings 6 inches asunder in the rows, drawing the soil to them so that only the tips of the critings are visible. When the stocks are to be budded, level down the ridges and insert the buds as low as possible. If you could place some gritty compost in the trenches formed for the cuttings they would rest more readily than in the very strong soil. more readily than in the very strong soil.

ADDRESS (Rev. H. Bullivani).—We never give the names of our correspondents without their permission, but we have sent your address to the writer of the article to which you refer, so that he can communicate with you if he desires to do so.

BOURSAULT ROSE (C,R).—The Boursault Rose was so named when the first double variety of Rose alpins was discovered, and named after a French cultivator of that name.

cuitivator of that name.

GROUND FOR VEGETABLES (H. Godderd).—Without knowing the nature of the soil, and whether you desire to have a full supply of Potatoes throughout the year, we cannot answer your question as to the precise extent of ground requisite for supplying twelve persons with versetables and small fruits, "allowing for a good deal of company." If the soil is fertile an acre of ground, if well managed and cropped, would yield a good supply of green vegetables in season with such roots as early Potatoes, Turnips, Carrots, Onions, &c., and the usunal small fruits. One man if wholly employed on that extent of ground ought to keep it in good order, if it is clean and in good workable condition to begin with.

Fireflye Tomaranes (Nombes).—There is we warmshiet rephilabed on the

FORCING TOMATOES (Novice).—There is no pamphlet published on the subject; but if you will state your requirements, and the conveniences at your disposal for growing the plants, we shall be able to furnish you with information that may assist you in carrying out your object.

PRUNING STEPHANOTIS (Subarriber).—If the growths are very much crowded you may thin out a portion of them, reserving the most prunising; but do not prune excessively nor shorten the growths more than needful at one operation. The soil in which the plant is growing may be kept drier in winter than in summer, but sufficient moisture must be affued just to keep the foliage fresh; the growths will then mature, and the vigour of the plant will not be impaired.

WINTERING ALOCASIAS AND CALADIUMS (Idem).— Alocasias should have sufficient water to keep the foliage fresh, and a minimum temperature of about 65°. Caladiums may be kept drier, withholding water gradually, and never letting the soil become dust dry. They should be wintered in a temperature of 60°, or not less than 55°, for many consecutive days or nights.

remperature of 60°, or not less than 55°, for many consecutive days or nights. PRESERVING BEDDING PELARGONIUMS (E. H.).—We fear your chance is not good of preserving the plants, seeing that you "cannot enjoy" the luxury of fines or fires, but have cold frames and straw to cover them. You may possibly save a portion of the plants by wintering them as you presee in a hayloft, provided frost is excluded. Had you inserted in September cuttings in 5-inch pots, about five or six cuttings in each pot, and left them in the open air until October, then kept them in frames until severe weather or damp suggested their removal to the windows of your dwelling, where they could have some light and not too much heat, you might have preserved a good portion of them, which would have made moderately good plants as bedding-out time. The best mode of preserving old plants with which we are acquaisted for those situated as you appear to be is to dig the plants up move and cut them down quite close to the original stem—that is, not leaving more than half an inch of the base of each branch. Trim the roots in also, cutting off all the small fibres and shortening the strong roots to within an inch or two of the base of the plant. You will then have a number of stamps not very pecunising in epipearance, yet with care and attestion nearly every stump will grow and form a good flowering plant next summer. Immediately the plants are pruned dress the wounds with freshly powdered lime to dry up the moisture, then pack them closely together in pots or bores, employing rather moist but not wet soil, and beat it as firmly round the roots as possible. The soil being moist and compressed, and the surface dasked with loose dry soil or sand, will retain sufficient moisture without frequent waterings to induce the emission of fresh rootlets from the old roots. At the same time a number of white buds will become wishle on the closely pruned tops, which in due time will form shoots. These shoots will probably be far too numerous, and should be thinne PRESERVING BEDDING PELARGONIUMS (E. H.).—We fear your chance is

hundreds of plants wintered successfully in the manner described.

PEAR CRACEUG (Mr. C. W.).—The fruit cracking is in most instances due to the unfavourableness of the climate, the cutide of the fruit being injured by inclement weather, and also often occurs when the trees make too much growth which does not ripen. This may to some extent to obvisted by root-pruning or lifting the trees, but when it arises from climatic conditions there is no remedy, although trees that have the fruit cracked when standing unprotected, often overcome this fault when planted against a wall. Except in warm situations in the southern counties Glou Morean requires a wall.

BORDER FOR PEACH TREES (Idem).—The subsell being unfavourable the border should not only be ladd with stones, but the joints should be comented, the border having a good fall from the wall to the frost, when there should be a pipe drain to carry off superfluous moisture. The border should be drained with brickstar or rubble 9 inches deep upon the fags, and have 21 to 24 inches depth of soil. For particulars of making the border see "Work for the Week."

BLACK HAMBURGER GRAPES INDIFFERENTLY COLOURED (Idem).—The

BLACK HAMBURGH GRAPES INDIFFERENTLY COLOURED (Idem).—The most probable cause of the Grapes not colouring is overcropping, though it may to some extent have been affected by a deficiency of ventilation when ripening, but the most likely cause is too heavy a crop.

STRIKING CONIFERS (Constant Reader).—Such small sprays as those enclosed will not strike so late in the season under handlights. You might try cuttings somewhat larger and firmer, inserting them in sand, and a few of them may, perhaps, emit roots. The evergreen is, we think, Andromeda angustifolia.

NAMES OF FRUITS (J. N.).—2, Adams' Pearmain; 3, Dumelow's Seedling; 5, Ribston Pippin; 6, London Pippin; 7, Court of Wick; Beurré Capisaumont Pear. (E. B., Croydon).—Souvenir du Congrès. (A. Z.).—The Apple is Ravelston Pippin, and the Pear Dunmore. (H. O.).—Nectarines: 1, Rivers' Orange; 2, Newington. Pseches: 1, Royal George; 3, Early Anne; but we cannot be certain about the names, as we do not know the character of the flowers. Pears: 1, Williams' Bon Chrêtien; 2, not known. (Elm).—1, Diamond; 2, We cannot determine without shoots or stalks; 3 quite decayed; 4, Jefferson; 5, Victoria; 6, Ickworth Impératrice. (K. G.).—We do not recognise the Apple in its present state. (A. T.).—Fondante d'Automne.

NAMES OF PLANTS (F. E. H.).—It is the double form of Scapwort (Saponaria officinalis). (J. R. Boya).—We have not received the flower to which you allude in your letter. (C. A. R.).—The white flower is Pyrethrum nlighnesum; the other resembles Helianthus multiflores. (A. C.).—1. Myrica Gale; ?, Rhus cotians; 3, Acanthus mollis; 4, Frankis subcordata; 5, Yucca flamentosa; 6, Ribes aureum. (S. H., Bristol).—I, Escallonia macrantha; 2, Selaginella cuspidata; 3, Specimen insufficient; 4, Francoa ramosa; 5, Tradescantia Warscewicziana; 6, Selaginella Willdenovi; 7, Begonia lucida. (Vise).—Hydranges japonica.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

CULTIVATION OF WINTER BARLEY.

WINTER barley has long been an important and useful green fodder crop, and is grown in various countries on the Continent, more particularly in Russia and other states where the climate and soil are not adapted for the growth of the best varieties, and for spring sowing, where the grain is required for malting purposes. It, however, is not used for mealing purposes, and in those latitudes where wheat is not grown winter barley, called "Bere" and "Bigg," forms a considerable portion of the food of the people, more particularly of the working classes. It makes but coarse bread, not equal by any means to that made from wheaten flour. This kind of barley is constantly imported into England, and is usually sold by the corn merchants at a low price for mealing purposes, and the price at which it can be purchased is the cause of its being used largely for mixing with other grain, such as maize, in the feeding of cattle and pigs; it is also used mixed with oats for the feeding of cab horses, &c. Winter barley is, however, when grown by the home farmer valued chiefly as a green fodder crop in admixture with winter vetches, and for this purpose it has no equal, rye being too forward in its growth for mixing with vetches.

There are several varieties of barley in cultivation for fodder purposes. The White Winter barley, called "Bere," is, however, most commonly sold in our markets, and as we propose to describe the varieties separately we will take the white one first This grain is of a thin elongated shape, with a very strong and tough awn, which makes it difficult to detach from the grain, and the grain weighs lighter in consequence, but as it is mostly grown for green fodder the actual weight per bushel is not of very much importance. The ears of this grain are of the cluster or square-headed shape; the straw is long and reedy, and is extremely well adapted for holding up a crop of vetches when they would otherwise lodge on the ground, in which case a portion of the crop would be discoloured at the bottom, and become distasteful to the sheep as well as cattle or horses. If the mixed crop is saved for seed, which is often done, the barley, by holding the vetches off the land, is very favourable for the podding of the vetches, and frequently when grown and threshed together yield a large crop for sale in the mixed state, and in this way it commands a ready sale for the home farmer. The object of mixing barley with vetches is also to protect them in the winter; and although the barley tillers out very much it does not leave the land so early as rye, yet it answers the purpose admirably as a shelter for the vetches. It is greatly in favour for that purpose upon the vale farms, where the mixed crop is required for large flocks of sheep and herds of cattle, &c., in the months of May, June, and part of July, after which time the summer vetches come in for use, and winter barley may also be sown with them in the spring, not only to hold up the crop, but because this mixed crop will keep longer in condition for feeding stock, for the winter barley will not grow so fast and overpower the vetches as oats are apt to do when sown in the

spring. This is a matter of importance when the green fodder can be held on to a later period, besides summer vetches are very subject to blight, particularly in a dry hot summer; but the effect of the winter barley when grown with them is to keep the land moist and otherwise prevent the vetches from being attacked by fungi called the red rust, or blight as it is commonly termed. This variety of barley grows well upon poor sandy or gravelly land almost as well as rye, but it certainly produces a much greater bulk of straw upon the mixed soils of vales. It is so much in demand for sowing with vetches that there is always a ready sale for the grain when a crop is sared for seed, for it becomes fit for harvesting almost as early as rye, and may be treated during growth in the same way. It should be drilled with about two and a half bushels of seed per acre, or three bushels if sown late, which quantity will be ample for sowing the land, as it tillers so much more than rye; but it is well to drill the seed at about 12 inches between the rows, in order that the land may be hoed in the spring if weedy.

order that the land may be hoed in the spring if weedy.

This crop, if saved for seed or mixed with vetches, should be sown about the middle of the month of October, and the preparation of the land is very simple, for it is usual to plough up a wheat or other corn stubble, work down and drill the seed; it is, however, not necessary to work the surface of the land very fine, but it should be left rather cloddy than otherwise, as the land and the crop then take the alternations of winter weather without injury. If the land is in poor condition or foul it should be autumn-cultivated and cleaned, and also receive about 2 cwt. of Peruvian guano sown broadcast immediately behind the drill and harrowed in. Whether the crop is saved for seed or used as green fodder it is essential that the land should be clean, in order that the succeeding crops may take better, as it is customary to grow turnips after the crop has been removed as green fodder, and, like rye, it may be followed by stubble turnips where the crop is reserved for seed. There is always a good demand for the seed, but the home farmer will always find it turn to good account for mealing purposes, with which to feed his cattle, sheep, or pigs. It is also a safe crop to grow as regards the yield per acre, for when the land is in good condition the bulk of straw being so stout and strong that it seldom becomes laid or lodged. It ripens very early, and is not subject to blight like some other cereals, and the ears of corn being square and plump the yield per acre at harvest is generally found to exceed the estimate.

The next variety of winter barley we have to notice is the black grain, called "Bigg." This had its origin in Russia, and is grown there in the coldest districts, and is therefore exceedis grown there in the contest instricts, and is therefore extendingly forward in growth, and very quickly ripens its grain. This variety of winter barley is not very common, but samples occasionally are met with. We first grew it in the year 1827, at which time we obtained a sack of it for trial from Peterborough in Northamptonshire, and it proved what it was recommended to be —a very hardy plant, and capable of standing the severest winter. The grain is of the same size and shape as the white variety, and the ears of corn are of the same character, but instead of lying about and tillering on the ground the black barley rises from the ground. It is even earlier in its growth than rye, with very strong succulent straw and a broader leaf than any other green fodder crop, and is therefore admirably adapted for sowing on the hill farms, where large flocks of ewes and lambs are kept as a breeding stock; particularly on farms where there are no water mesdows, because it not only comes earlier than rye, but produces a more bulky crop. It is rather too early in its growth for sowing with winter vetches upon good land on the vale farms; but upon the hill districts of poor thin land, and especially is averaged eitherstons; it wower a valuable protection for the ally in exposed situations, it proves a valuable protection for the vetches in the winter months, and is also extremely well calculated for constant with the control of th lated for sowing with summer vetches in the spring, because it grows so quickly and is so strong and reedy in the stem that it holds up the heaviest crop of vetches which can be produced. In saving this crop for seed it should be drilled, and at the same width as before stated for the white barley, and at the same width as before stated for the white barley, and in our experience we have found it yield a full crop of corn, and rather in excess of the white variety. As the black barley does not tiller out, but grows more hollow at bottom, it offers a capital opportunity for sowing with clover and other grasses, for when the corn is cut, it being so early, it may be cut above the clover, as we often do with early white cats, in which case in ordinary seasons we are sure of a good cutting of clover for soiling cattle and horses until the latest period when frost commences. The seed is not very easily obtained, but we have lately seen a bulk selling in a local market, and it was quickly bought up for seeding with winter vetches on the chalk hill farms, the price made being 6s. per bushel.

WORK ON THE HOME FARM.

Horse Labour.—The preparation of land and sowing of wheat will now engage the farmer's chief attention. Many farmers advocate the sowing of wheat before the 14th of October, but that applies to the cold and heavy soils and to the backward districts as regards climate. In the southern and eastern counties, how-

ever, it is well to defer the sowing of wheat until the last week of October and the first fortnight of November. In a backward harvest like it has been this year all the usual work on the farm has been in arrears, such as sowing trifolium, rye, winter vetches, &c., so that little cleaning of the stubbles has been done this autumn, and it is too late now to commence that work; therefore, entire attention will now be centred in the wheat season. In last week's "Work" we named some of the best varieties of wheat, both red and white, but we must now call attention to the question of change of soil as well as selection. The question of pedigree, too, is well worth attention, for it has been proved by Major Hallett that there is as great advantage in selection and propagating from the best specimens of cereals as there is in the raising of cattle from the best animals, thus proving that like begets like in either case. It is well, therefore, for the home farmer to consider that after having decided upon the best variety of wheat adapted for the soil and climate of which he has the management the propriety of endeavouring to obtain a pedigree sample for seed of the sort which he intends sowing, and if possible to get it from a district which shall be a change of soil and climate. It is time now that all the yard or town manure intended to be laid out upon the fallows should be completed. We fear, however, that upon some farms, unless we get a change to settled dry weather, the land will be too wet for carting out manure at all upon fallowed land; it will then of course be laid out upon the clover leas, as that work may be done should the weather prove showery. It must, however, not be thought that we wish the fallows to be sown without manure; but to illustrate our recommendation upon the subject we will state our plan pursued in the seed time of 1872, which was one of the worst we can recollect for many years upon strong soils that are usually sown after a fallow preparation. Upon that occasion we had about forty acres of fallow to be sown with wheat upon a farm under our agency. It was a loamy sown with wheat upon a farm under our agency. It was a loamy soil upon clay, and as the land was too wet for the ordinary mode of proceeding we opened two furrows for a veering throughout the fields. This not only laid the land drier by taking away the excessive rainfall, but it enabled us to sow the 3 cwt. of Peruvian guano per acre which we used by sowing broadcast between the veerings just before the ploughing daily; and in this way we not only avoided giving the land a double dressing in the centre of the ridges but buried it under furrow, so as to benefit the corn immediately it vegetated. As fast as the land was ploughed the wheat was sown by hand broadcast, and harrowed-in one or two times with the iron harrows, the horses going in the furrows, and times with the iron harrows, the horses going in the furrows, and thus the sowing was completed as fast as the land was ploughed; and we venture to recommend this plan as the only available method in a difficult season, and upon fallow land when manure cannot be carted on to it.

Hand Labour.—Men may now be employed with advantage in going over the pastures with the soythe, cutting off any patches of rushes or coarse grass refused by the cattle, for if the winter proves mild the young grasses which will spring up will be easily eaten by the cattle. If rushes and coarse grasses are left during the winter they are sure to prejudice the growth of the better herbage in the spring. We know cases in which such-like coarse grass, sedge, rushes, &c., are carefully reserved when they can be got into stack dry and cut up with straw into chaff for dairy cows in the winter, and it answers a good purpose by making the straw more palatable, and is more readily eaten by the cattle. It is, however, by the best managers connected with pulped roots, cake, or meal. The shepherds will now have to pay attention in the feeding of the ewes, for in all the districts where Down sheep are kept the ewes will have been served and the rams taken away from them by this time, and they should be cared for accordingly, by having at least two changes per day of grass—such as old lea or saintfoin lea—with a fold of mustard or similar food in moderate quantity at night. The long-wooled ewes will still have the rams with them, and should in consequence be kept well with a more generous diet, with changes of food from pasture to arable produce daily. A liberal dietary will at lambing time give a larger number of twin lambs; and to show the difference of the lambing periods of different districts the horned Dorset and Somerset ewes usually kept in the home and southern counties, and just arrived at their new home from the early fairs, will begin lambing immediately. These ewes will require good clover grass and stabble grass feeding both before and after lambing; and as they usually finish lambing by the middle or end of November, the ewes do not require a lambing fold like the Down sheep which lamb two months later, but they should be kept at night in a fold upon dry pasture or old lea on a sheltered spot, to enable the she

WEST VIRGINIA AS A FIELD FOR EMIGRATION.

FOR some months past there have been many suggestions as to the best ways or means of treating the present depression of the farming interest in this country. I beg to draw the attention of your readers who contemplate a change in their occupation as tenant farmers and others to South-west Virginia, one of the healthiest

positions in the United States. The heat in summer is much less than that of Texas; and the winters, in place of being oftentimes 20° below zero, as in the north-western States, seldom reach freezing point in South-west Virginia. The lands are situated within three hundred miles of the Atlantic seaboard, and the price per acre does not exceed 4s., at which cost they would obtain their own freeholds. The streams abound in fish; the scenery is beautiful beyond description, and there is railway communication with all the great cities of the Atlantic coast, comprising New York, Boston, Philadelphia, and Baltimore, and the great inland cities of Chicago, St. Louis, Cincinnati, Louisville, and Richmond. Coal, iron, and other minerals are in abundance, and the climate is unsurpassingly fine with clear bright skies. I shall be glad to give any further particulars concerning these lands.—EDWARD BREWIS.

FORTHCOMING POULTRY SHOWS.

WE have before us a number of schedules of forthcoming poultry shows. The fourth Columbarian and Bantam Show will be held at Southport in the Winter Gardens on October 29th and 30th. The classification for Pigeons is the most complete we ever remember having seen. There are 105 classes in all, comprising six for Pouters, ten for Carriers, twelve for Barbs, sixteen for English Owls, &c. The classes for Bantams are fifteen; we regret to see that no encouragement is given to the rarer varieties. There are ten point cups and fifteen other cups offered. The great feature of the Show is that it is only open to amateurs.

Birmingham continues much in its old groove. The Dorking cups and prizes seem year by year reduced; the result is that the grand collections of that breed once to be seen in Bingley Hall are by no means equalled in these days. Langshans have two classes with four prizes in each, the first prizes being £4. If fanciers of other varieties were as liberal as those of Langshans the prize list might be a better one. Polish still have separate classes for adults and chickens, but Hamburghs are mixed. Ducks are well off; there are separate classes for Pekins, Cayugas, Mandarins, Carolinas, and Call Ducks, besides the usual varieties. There seem hardly any changes in the Pigeon classes. We miss the name of Mr. Baily from the list of Judges; doubtless he has claimed a well-earned exemption from the labours of Judge, after having officiated at every Show since their establishment thirty years ago.

years ago.

The Rutland Agricultural Society's Exhibition will be held at Oakham as usual on November 26th and 27th. Its schedule is on the whole much the same as in former years, though in some classes the prize money has been much reduced.

HOW TO FOUND A ROOKERY.

IN answer to the question that has been asked in your columns as to the best means of founding a rookery, I can mention an instance in which a large one was established by the kindness shown to a solitary Rook one severe winter. For many years it had been our great ambition to have a rookery; there were several large ones in other parts of Cheshire, and what was considered to be the mother rookery was about two miles from us. The keeper had obtained Rooks' eggs, placed them in nests in tall trees thought likely to attract them, but all to no purpose. But one severe winter there came regularly every day, with some pet Bantams that were fed by the housekeeper out of the window, a solitary Rook and fed with them, becoming at last so tame as to hop on the window sill. In the spring this tame Rook brought a mate, and together they began to build in a small Spanish chest-nut tree, so close to the house that from the upper windows we could see quite into the nest. It made great excitement watching the progress of this nest, as it is considered to bring good luck to a house when Rooks build near it. The nest was about half finished, when, one morning, a great noise was heard, and we saw about a dozen strange Rooks violently attacking the old par, and tearing the nest to pieces. They did not attempt to build again that year, but the next spring the same thing occurred. They got so far as to lay their eggs, when the female bird was suddenly attacked one morning when she was sitting by a dozen and more of Rooks, and the noise was such as to collect the whole household to watch the battle. She made a stout defence, and it was some time before they beat her off the nest, dashing it with its contents to the ground. This was repeated a third year, when we began to despair of having our rookery, but on consulting a book on natural history we found it stated that it was generally four years before a pair were allowed to establish themselves independently from the mother rookery. At all events it was so in this case, for the fol

instinct that Rooks are supposed to have with regard to trees that are destined to come down, though they were left in peaceful possession of the original tree they had chosen, and which had nine nests in it, they wisely left it, and established themselves in a clump of large trees at a more convenient distance. Every year after this the rookery increased in size, and in the space of ten years from the time the parent birds made their first attempt to build, the rookery has grown so large that we have been advised to shoot some of them in the spring, for fear the Rooks, "becoming too numerous" should fight and break up the colony. This is only one more instance of the power of man over animals, and shows that the secret of that power is kindness.—Mrs. Tilt

(in Science Gossip).

VARIETIES.

"HARVEST work," says the Agricultural Gazette, "is still far from complete in English midland counties, and has been little more than begun in many an upland corn-growing district in the north. Although the dry weather of the last few days has been most serviceable it has come long after the ordinary termination of the harvest season, and it is not too much to say that hardly any corn was carried in the month of September in all Scotland. Potatoes, which are such a resource on most Scottish farms, are but an uncertain prop in this most disastrous year. During a recent run through Fifeshire we heard of instances in which the crop had been sold for £40 an acre; but, more generally, there was hardly the 'seed' again as a return. Where the land was free and dry the produce was, to all appearance, both safe and good; where clayey, wet, and cold it was either ruined by disease or had never got beyond the size of 'chats.'"

— Where requested by Mr. C. Cashmore to state that, although his name was attached to the protest relative to the contest of incubators at Hemel Hempstead that appeared in our advertising columns, such protest was published without his knowledge and

THE fourth annual Show of the British Dairy Farmers' Association commenced at Islington on Monday, and will remain open until Friday night. The Show is a very large one, the total number of entries being two hundred in excess of last year, and it number of entries being two hundred in excess of last year, and it is satisfactory to note a slight increase in the number of cattle—247 as against 282. In addition to the cattle there is a large exhibition of goats, butter, cheese, dairy utensils of every description, models of dairy buildings, and a show of poultry. The butter, cheese, and dairy utensils occupy the centre of the ground floor, the cattle being ranged upon each side, while the goats and kids are placed in the southern corner. The exhibits are well arranged, and the flow is a successful one. and the Show is a successful one.

—— CANADIAN POTATOES.—A letter from Canada received by a merchant in Newcastle-on-Tyne states—"After all the fears about the potato bug our crops of potatoes are excellent; those grown on high and well-drained lands are in a fine condition. Large quantities are being shipped by steamers to England. The prices realised in Canada by the farmers are only 6d. a bushel. A bushel is about four imperial stones, English weight." Considering the reputable high rate of wages in Canada we can scarcely understand how the crop at the price quoted can pay for digging and leave a margin of profit for the cultivator.

As an instance of the lateness of the season we may record that less than a week ago we observed in the neighbourhood of Chesterfield several acres of grass that had only just been cut in the hope of converting it into hay, this being the first cutting of the season. Several fields of corn, both wheat and barley, were quite green, and it is quite impossible that the grain can ripen.

SPECULATION IN AMERICAN CHEESE.—After a long period of depression the market for one description of American proof depression the market for one description of American pro-visions, that of cheese, has undergone a change which is perhaps unprecedented. In a space of five weeks the value of the article has risen from 80 to 100 per cent. It appears that the late spring in America had the effect of materially reducing the make in April and May, and the ground thus lost has never been recovered; and finding this to be the case one large cheese merchant in Liverpool promptly went into the market and bought up all the cheese that could be obtained. The sudden demand caused a rise in price; but as the summer in America has been exceedingly hot, and her had the start of having up the next was the fall you. and has had the effect of burning up the pastures, the fall make of cheese proves to be less than it has been for some years past, and as all the cheese imported is practically in the hands of this enterprising speculator he will probably be able to force prices up to a point still higher than they have at present reached.

—— SUBSTITUTES FOR POTATOES.—We are threatened with something like a potato famine, and those who remember the similar disaster of 1846 do not need to be told how grave is now the prospect, with a vastly increased population, and a state of depression in trade which signifies on the part of the masses a great difficulty in providing even the commonest and cheapest necessaries of life. Many and well-intentioned are the suggestions which are being made with the view of providing substitutes for

the potato. The French haricot blancs or flageolets, lentils, rice, maize, and catmeal are the substances which are brought most maize, and catmeal are the substances which are brought most prominently forward as being fit to replace the favourite tuber. In one respect—the quantity of nitrogen which they contain— they all, but especially the leguminous examples, greatly surpass the potato as an economical nutriment, but unfortunately they are all deficient in antiscorbutic elements. Under a diet of these are all dencient in antiscorbutic elements. Under a diet of these substances, either alone or with the trifling amount of fresh animal food which is all that tens of thousands of persons can obtain, scurvy would be as rife as it was in Ireland and North Britain in 1846-47. Nevertheless, all these foods are very valuable, and it only needs that the particular point in which they fail should be recognised and supplemented. If this be not done disease must ensue and the nutriment fall into disfavour. Any of these substances may be used with advantage where either an abundance of milk forms part of the dietary or the antiscorbutic element can be furnished by fresh green vegetables, onions, or the juice of oranges furnished by fresh green vegetables, onions, or the juice of oranges or lemons.—(Lancet.)

FOUL BROOD AND ITS PREVENTION.

I HAVE read with much interest the exhaustive paper on "Foul Brood" with which we have been favoured from the pen of Mr. Cheshire, whom all the apiarian readers of this Journal will welcome as a contributor to its pages. The account he gives us of this horrible and infectious disease, which he seems to think is apprending mortally in this country, in apprendice. of this horrible and infectious disease, which he seems to think is spreading rapidly in this country, is enough to make all beekeepers quake with alarm. For although he gives us a remedy, which, from the experience of his friend Mr. Cowan seems to be a specific, it is perfectly certain that none but the very few will ever have recourse to it. These few will be found scattered up and down the country at considerable distances, including the animal of the semantary and the commercial beekeeper. But scientific, the amateur, and the commercial bee-keeper. But among the great mass of cottage bee-keepers scarcely one in a thousand will take the trouble to doctor their infected hives, and so the disease will spread practically unohecked through the length and breadth of the land. Hitherto, I am thankful to say, my own apiary has escaped the plague, nor, indeed, as yet have I come across a single case of foul brood in all the forty years I have been a bee-keeper, and I think it is as much a stranger in this part of Somersetshire as in any part of England. We all remember the experience of our lamented captain, Mr. Woodbury, in Devonshire, who had it among his hives again and again, and the great trouble he took to get rid of it, sometimes at the cost of breaking up his most valuable hives.

Seeing, then, the impossibility of successfully coping with the disease if it once gets the footing among us which Mr. Cheshire seems to fear, the question arises, How far it is possible to check its dissemination? And it is in the interest of prevention that I now write, which all men have agreed to believe is "better than cure."

First, one would like to know whence the disease came. I have always thought that it came from abroad, and that the invasion atways thought that it came from abroad, and that the interest of the Italian breed of bees. Is this a mere fancy, or is it a fact? I think it will be found that it appeared in America, and probably in Germany, at the same time these foreign bees made their appearance in those countries. If so, it behaves all importers of Italian queens to be very careful to avoid the introduction of any such from apiaries which may be infected. There should be some guarantee, founded on personal experience gained on the spot, that none are brought into England which are not warranted to have come from perfectly

healthy bee farms.

All readers of Virgil's fourth Georgic will remember his graphic description of the plague which visited the apiary of Aristæus—

"Amissis, ut fama, apibus morboque fameque."

We may be sure that the poet did not draw upon his imagination only, but that he was describing probably some visitation from which his own bees had suffered, over which he mourned himself, though in the name of another. What was this disease but foul brood? If so, no wonder that Italy should be now the focus of the mischief, and that every consignment of queens from that country is but spreading among us more and more fatally the complaint we dread so much. Yet I do not think that we should have to apprehend much danger from imported queens and the nave to apprehend much danger from imported queens and the few bees that accompany them, provided that no comb save perfectly fresh virgin honeycomb was introduced with the bees into the little boxes in which they travel. Surely this could be made a sine qua non with all who are engaged in the traffic. A condition of payment should include what I suggest. In this way the chance of germs of the micrococcus finding their way in future into this country would be adventured. into this country would be reduced to a minimum.

So far so good, but what of the disease actually domiciled among so tar so good, but what of the disease actually domiciled among us? How are we to guard against its dissemination? For my own part I am fully resolved to introduce no bees from any quarter whatever into my apiary unless I am sure of the quarter from whence they come. I expect that this winter will find half the apiaries of England empty. If so, let us hope that there will also be a stampede of foul-brood germs. But with the coming spring those apiarians, young or old, who have not given way to despon-

dency will be buying hives and swarms in all directions wheresoever they may have survived. It is not unlikely there will thus distribution of bees all over the land, calculated to do infinite harm if not wisely managed, by spreading the infection far and wide. Therefore, let every purchaser of bees next spring take double care to ascertain that foul brood is not imported from any quarter by a careless introduction of stocks or swarms. Let all he buys be warranted to be sent from a pure and healthy locality unknowing of the disease. If possible let him see to thus

By these simple means I should hope that in a few years this plague would become as rare as cholera now is among ourselves. Meanwhile we thank Mr. Cheshire with all our heart for directing attention to the matter. Let everyone who has reason to dread attention to the matter. Let everyone who has assent to the fate of Aristens use the remedy now recommended, which seems to be efficacious; but above all things let him, if possible, guard against its coming within his knowledge at all. I shall certainly adopt the receipe for autumn and winter feeding which Mr. Cheshire recommends. It should now be speedily administered.

THINGS KNOWN AND THINGS UNKNOWN.

It is known that late hatches of brood can be obtained by continued vigorous artificial feeding, but probably nobody dare assert that the production of eggs at a late or untimely season affects the fertility of a queen for early work in the spring following. Naturally and by analogical reasoning some think that six months' rest or cessation from egg-laying would be better and more healthful for a queen bee than four months' rest. This is an old question which in our opinion has never been satisfactorily settled. Though we have not made carefully marked experiments on this point, observations have led to the conclusion that egg-laying caused by stimulative treatment late in autumn does not weaken the pro-

ductive powers of queens for any length of time.

ductive powers of queens for any length of time.

The question of increasing the fertility of queens by feeding stocks with candy cakes, which are made of peameal, sugar, and water, was prominently noticed in this Journal last spring. The novelty of this idea and that of queens being fed with half-digested food from the stomachs of working bees pleased many apiarians at the time. Though the past summer has been very unfavourable for experiments in the apiary as well as for honey-cathering, some who tried the candy cakes and barley bannocks gathering, some who tried the candy cakes and barley bannocks may be able to give us their opinions as to their worth. If it be proved than when used as food for bees queens commence to lay, their use at certain seasons cannot be too strongly recommended. The statement about queens being fed on half-digested food is a most interesting one, presenting to the minds of thoughtful apiarians a new and economic feature of bee life. The honey bag, used as a reservoir, filled and emptied with facility at will, is a most important and interesting instrument and organ. We are told by those who write on the anatomy of the bee, that from the honey bag "the food may either be returned to the mouth or pass into the true stomach just below. The honey when it is taken from the flowers is stored in the honey bag until the bee In that organ it appears to undergo a change, reaches home. reaches nome. In that organ it appears to undergo a change, which gives it the peculiar opacity and consistence so characteristic of good honey. In fact, the honey bag performs much the same functions in the bee that the ruminating stomach does in the cow. At the lower part of the honey bag the valve is seen which admits the food through a short neck to the true stomach. This is a cylindrical organ, increasing in diameter slightly after leaving the honey bag, and bound by innumerable muscular rings. When the food has reached this point it is beyond the control of the bee, and cannot be regurgitated." If this statement is correct it is antagonistic to the hypothesis (if it is a hypothesis merely), that queens are fed with half-digested food from the stomachs of the working community. Neither view is without difficulty. Evidently much remains unknown, but future research will probably bring truth into full view and confidence.—A. PETTIGREW.

OUR LETTER BOX.

DUCKLING PARALYSED (Mary Jones) .- There is no known remedy. Give it only soft food. If it survives and becomes large enough for being eaten the affection of the head need not prevent its being so used.

BEES FIGHTING (H. P.).—Move one of the hives far away from the other. An old writer says

"A little dust cast up on high, Doth end the quarrel presently."

DEAD BEES (Busy).—We have examined your percel of dead bees, which appear to be the ordinary British bee, certainly not Ligurian. They look like the usual type of bee which has recently died from natural causes. There is no foul smell about them, nor any reason to suppose any special cause of death except it be starvation. We should like to know something of your mode of feeding and the quantity you have given them, as we suspect they must have been fed ina/equately. Try what an immediate and liberal supply of food will do for the survivore, if any of them are yet alive. There must certainly be something wrong in your method of feeding to allow of must certainly be something wrong in your method of feeding to allow of any being "stuck in the thicker syrup," and requiring to be brought to active life by being "sprayed over with warm water." Your shed seems unobjectionable. Of course, when the shutter is on there are holes in it corre-

spending to the entrance holes of the hives, by which the bees can make their exit?

their exit?

PARAFFIN FOR COMBS (G. T., Ashton-ender-Lyne).—Paraffin does not answer for combs. The quantities of it that are soft enough to enable the bees to work it into comb melt at too low a temperature to stand the ardent rays of summer. Wax melts at 180° Fahr, and it is tolerably tough at only a few degrees lower than its melting point. Mr. Root of America stated paraffin to be a success before he had really given time for a fair trial. Bees may be quite successfully kept in the top of a house, but efforts should be made to screak them from all driving winds. The mere height from the ground would not give them trouble, for, as an American somewhere says, bees having wings can get over a very high fence."

PRODE PRINT OF ROUTH PROPERTY OF A Carety - Salicytic.

"bess having wings can get over a very high fence."

FOOD FOR BEES IN FOUL-BECODY DISTRICTS (F. J., Cork).—Salicylic acid is a white light powder. It is better to deal with the acid itself than buy any solution of the chemist, as the strength of such solution being unknown you are without certain guide as to quantity to use. The price of the acid is about 1s. an ounce, and the readiest way to employ it is to throw the powder into the making syrup while it is on the fire, a small teaspoonful, as we stated in last issue, being sufficient for 14 fibs. of sugar. If you make according to Mr. Cowan's recips, 1 oz. of the holution (which is only one part in eighty-two salicylic acid (see October Ind) and contains therefore rather less than 6 grains), is added to 10 fibs. of sugar. Salicylic acid is not poisonous, but it is not desirable to use more than enough; and as you are only intent on guarding against a possible outbreak we should suggest half a teaspoonful (18 grains) of the dry acid as being amply sufficient for 14 fibs.

of sugar.

COMES HEALTHY OB NOT (P. McArthur, Manyfeld).—The piece of comb sent us is perfectly healthy. The drone it contained was completely developed, whereas had it died from the effect of micrococcus its remains would have been brown, fostid, and viscid. Why did you suspect foul brood in this specimen which contains nothing to indicate it? Because this specimen is healthy, however, it does not of necessity follow that the hive is nowhere tainted, but the presence of disease we should consider highly improbable. The American-made sections can be had of Messrs. Neighbour, 149, Regent Street, while several English makers advertise their own.

149, Regent Street, while several English makers advertise their own.

PRICELY COMPREY (E. C. O.).—Symphytum asperrimum is the species employed on farms for cattle-feeding purposes. It was introduced from the Cancasus in 1799. It is cut and given to the cattle in a green state, or partially withsterd, and in rich, deep, and rather moist soil it yields very large crops of produce. Divisions of the roots may be planted 3 feet spart, from November onwards, in well-enriched soil; indeed, the preparation of the soil and mode of culture usually applied to rhubarb are precisely suitable for the prickly comfrey, which is quite hardy. We do not know whether hares or rabbits eat the plants and do them injury. Perhaps some of our correspondents can inform us on this point.

REMARES.

Sth.—Cloudy day, scarcely a glimpse of sunshine.

9th.—Cloudy; generally overcast throughout the day.

10th.—Foggy in first part of morning, and cool; cloudy till 5.30 P.M., then clear and fine; nearly cloudiess at night.

11th.—Very foggy morning, sun shining through mist in forencon; foggy in afternoon and part of evening.

12th.—Dull, overcast, and rather thick throughout the day; damp fog at 10 P.M.

18th.—Slight fog in morning; fair but dull day.

14th.—Misty morning, overcast until 2.50 P.M., little sunshine for short time, and finer afternoon and evening; gusty shower of wind and rain

Much colder, and noticeable for very high barometer; much fog, but very little rain. On several nights the temperature upon the grass has been warmer than in the air; this occurs when the ground is relatively warm, and when radiation is stopped by fog or cloud.—G. J. Simons.

COVENT GARDEN MARKET .- OCTOBER 15.

WE have no remark to make this week beyond stating that now the soft fruit is nearly finished our market has settled down to a quiet business, prices of all classes of fruit being with difficulty maintained. PRUIT.

From observations taken near London during forty-three years, the average day temperature of the week is 55.7°; and its night temperature 37.8°.

APRICOT BRANCHES DYING.

HE Apricot being one of our most useful fruits either for dessert, kitchen, or preserving, a fair share of attention is naturally devoted to it in most gardens; but how frequently we see trees with ugly gaps in them and the labour of years set at naught by the dyingout of some of the branches, which often are those that can be least spared. Trees are subject

to this disfigurement, and not unfrequently ruin, in various soils. In some gardens, however, Apricot trees grow healthily whether the soil is light or strong, so that the origin of the evil referred to is not exclusively hidden below the ground. We must therefore seek for the cause in another direction.

Many theories have been advanced from time to time explaining the causes conducing to the unfortunate state of things which makes the cultivation of this fruit so perplexing; and it is certainly unsatisfactory to be obliged to look upon "branch dying" in Apricots as incurable. Besides unsuitable soil an excessive use of the pruning knife, exposure of bare branches to sun and frost, the check occasioned by old scraggy or dead spurs and climate, have all had a share of the blame. Most likely all these are causes that more or less affect the circulation of sap, and thus local obstructions are formed which in time, through the accumulation of diseased tissues, cause the branches to die.

But I fear we have yet another agent working as ill effects as any of the causes mentioned, if not in reality the first cause in many cases. I allude to a small borer which I find is causing much injury to our Apricot trees here, although in a way that is not likely to attract observation, the ejected debris of bark and alburnum being of a light brown colour, inconspicuous and small in quantity compared with the internal ravages.

Six years ago I planted against a wall a number of Apricot trees, which have done well; in fact have quite covered the spaces allotted to them, the riders having had to be removed a year ago to afford additional space. went well till this season, when several branches died off; most trees lost one, some more. I naturally felt disappointed in thus having the symmetry spoiled of trees of which I was a little proud because of their rapid extension combined

with fruitfulness.

The various theories advanced were intently thought over, and each in turn dismissed as seemingly inapplicable. The several causes of check which are said to form local centres of gum seemed entirely absent, there being ample foliage covering every branch, the stock only being exposed to the action of the sun, even the junction of stock and scion being fairly shaded. There were no old spurs; the knife had never been used except to cut any weakly shoot back to a few eyes to cause a strong start, and to cut back the strong centre shoot the first year or two sufficiently to insure a well-furnished middle to each tree. All other growths required had been laid in at full length (frequently 4 feet in one season) and the balance maintained where necessary

by summer pinching, and this may be said to be all the pruning they ever had. Finally, there was no gum on the trees from which the branches died. Thus there appeared to be thorough healthiness in every part, yet there were the blanks which came without giving a sign until the young starting growths hung flagging and withered on the branches in the spring.

Last month I observed here and there, perhaps in two places on a tree, a little brownish sawdust-like substance on branches near their junction with the main stem; it appeared less than might easily be laid on the head of a tintack, but on looking in the clefts between the branches more was observable, and on cutting out a piece of bark a grub was discovered which was about a third of an inch in length. From one piece of branch I extracted over a dozen of these larvæ, and in other places three or four specimens were found. Their tunnels are very small, but complicated and winding; it is therefore difficult to get them out whole without doing unnecessary damage to the tree, as the insects are very soft with the exception of their head. However, I succeeded in getting out five whole and alive, three of which were sent to the office of the Journal of Horticulture for identification; the other two, unfortunately, made their escape. In two instances the branches affected were almost encircled by their operations, although there was little to be observed outwardly, which renders it the more necessary to direct attention to the subject.

There is now a considerable amount of gum exuding at the places from which the larvæ were extracted, but I trust to be able to save the branches; whereas if the grubs had had a little more time unobserved the result might have been a ringed limb, which would have started into growth next season only to wither and die, while remaining apparently sound all the winter. Supposing their workings not to have proceeded to such an extent as to cause the direct loss of the limb, it is certainly probable that the surrounding cambium would become surcharged with gum, the formation of woody fibre would cease, all alimentary supplies reaching that point would only increase the evil, and if the affected part were not cut out entirely (when healthy bark might in time cover the wound) there would be little chance of circulation ever being re-established on the injured side of the branch. I do not infer that those borers are the cause of dying Apricot limbs generally, as, until there is further evidence forthcoming as to their existence and depredations from other cultivators of the Apricot, it would be premature to do so; but I think that it may be the cause in some cases, and especially would it be well to keep a sharp lookout when other causes seem absent.—R. CROSSLING, St. Fagan's.

[The larvæ sent prove to be those of Sesia myopæformis, also called the "Apple Clearwing," a small fly-like moth. Though named from the Apple, it is as frequently found infesting the Pear, where several dozen of the larvæ have been sometimes removed from a single branch. That the moths should deposit eggs upon the Apricot is an unusual, yet quite possible, circumstance. There is no certain mode of preventing its attacks beyond the destruction of infected branches or shoots, and the rather tedious process of catching

any moths seen on the wing during their period of flight, which lasts about a fortnight from midsummer.—EDS.]

POTATO CULTURE.

YOUR correspondent, "A SURREY PHYSICIAN," wishes for information from others with regard to the advantage or otherwise of earthing-up Potatoes. I willingly give him the benefit of my experience. I have on several occasions tried the non-earthing plan, and the result has always been a failure. One ought not to lay down a hard-and-fast line for all occasions with regard to the cultivation of the soil, and he may have been right in the course he pursued in the present year, but I should not recommend it for the future. The more they are earthed-up the less liable they are to disease. In the case of those that were injured the operation was delayed too long. From the great similarity of the early part of the season now past to that of 1860 I thought we might escape with but little disease, but unfortunately this has been a worse year than 1860. The latter half of July with its damp and warm atmosphere was fatal, whereas in 1860 this period was fine. The rain, too, since that time has been excessive. The Magnum Bonum, it appears, has resisted the attacks of the disease well, and if of good quality must be a valuable variety. Perhaps "A SURREY PHYSICIAN" can enlighten us on this point. It is not fair in all cases to judge this year, but he has grown it during other years .- AMATEUR, Cirencester.

THE ROSE ELECTION. THE NEWER EXHIBITION VARIETIES.

It is a satisfaction to arrive at the termination of a task, even though that task may be in a great degree a pleasure, for as the witty Hood remarks, even

"One of the pleasures of having a rout Is the pleasure of having it over."

So it is satisfactory to be able to say, "That is done at any rate;" still, "If't were done, 't were well it were well done; and if it were well done, 't were well it were done quickly." In both of these points I confess to failure; as to the latter, a variety of circumstances seem to have conspired together to delay the appearance of the poll. I can only say I have struggled to send it out earlier. As to the former portion, I must allow that of all the Rose elections it has been my fortune to conduct this has been to myself the least satisfactory; indeed the election has, like some of the candidates, been somewhat thorny.

Roses, fortunately for themselves perhaps, do not carry their age in their mouth, as up to a "certain age" doour equine friends; and where a question of age has arisen, and very many have occurred, the preux cheralier has been nothing loth to place his lance in rest, not always with the button on the point, and vouch for the age, always a delicate point, of the specimen of our flower queen he may have selected—aye, as ready as were the old mailed champions of former ages to do battle for the fair ones of their choice. I have had to question not a few of the returns, indeed very few have not taken several postal trips, and I cannot but fear that by such doubts I have unintentionally given some offence. As we were restricting the inquiry to a "certain age" it certainly appeared to me my legitimate task that I should question a vote of doubtful character. I have done so, I trust, without considering that I possessed greater knowledge, and fully conscious of the difficulties which beset the elector. If I have in the hurry of an unusually occupied period appeared to do so in a wrong spirit, I exceedingly regret it; I may have been misunderstood, and therefore if I have unwillingly or unwittingly given offence to any elector I now plead to be forgiven, and hereby offer as ample an apology as I can. On the other hand, I gratefully acknowledge the assistance given me by others; and I would specially mention Mr. Baker of Reigate, to whom, personally unknown, I feel much indebted for notes on newer varieties.

Would that some enterprising rosarians amongst our nurserymen would bestow a little extra labour on their catalogues, and give us the age and the raiser's name of some of our Roses. It seems to me this would be far more interesting to Rose-growers than flaming descriptions as to form and wood, which are often unverified by the results. The Rose elections of past years have, I presume, settled the ages of some few, and as the list has not been found fault with we may presume it is correct, But how many are without age, a local habitation, and a name, at least of the raisers! Even amongst the new Roses the raiser's

name is frequently omitted, or given only where the Rose has been raised or sent out by the firm, and in not a few cases the Roses are found only in the catalogue of the raiser, having long since been tried by others and found wanting. In this respect some of the foreign catalogues are a great improvement on those of our own nurserymen, and what information I have been able to get as to dates and raisers' names has come chiefly from them; possibly it may be faulty, but such as it is I give it for what it is worth. It will be noted that there are some blanks to fill up.

Should in future years an election of newer exhibition varieties be attempted, I would strongly urge that the recently admitted Roses should be omitted. I believe the present election would have been more valuable and ultimately more reliable if the years had been from 1872 to 1877 inclusive. It is doubtful work judging recent introductions, and in my experience I have noticed not a few predictions utterly falsified, and it seems to me that at least two years' trial is necessary to form an opinion.

And now as to the poll. Most of the headings of the columns speak for themselves; the A, B, and C representing the first, second, and third class votes given by amateurs; the same letters with the asterisks denote the votes of nurserymen.

Four votes were obtained by eleven candidates, whilst thirteen obtained three votes; nineteen were only mentioned twice, and no less than fifty out of the 148 Roses named obtained but a solitary vote. It seems marvellous that with only twenty-four voters as many Roses should receive but solitary notice, yet so it is.

Contrasting this list with the last election list there is one point that stands out in very bold relief and is exceedingly gratifying, that is the increasing number of varieties which our English raisers, in spite of the difficulties of climate, have

managed to bring into the fifty-five tabulated Roses. Giving the foreign growers the benefit of those Roses unattachedalthough I believe one, Madame Welsh, is English—they have yet succeeded in placing amongst the best fifty-five no fewer than twenty-two Roses; whilst in the tabulated seventy-two Roses of last year's election only thirteen English Roses were named, and most of these were very low down in the list.

Two or three of the returns have not been included, being incomplete or otherwise informal, as, for instance, when only twelve or twenty-four varieties have been maned instead of the thirty-six baked for. It is manifest that the twenty-four named thus receive a great advantage in position which cer-

tainly a dozen more ought to share.

One Rose stands well in the front considering its youth, and that is A. K. Williams. As an exhibition variety it will pro-bably rank very highly, distancing some of those now placed higher. It will be noted by those who examine the hat that in first-class votes alone A. K. Williams would come third. I may also state that Marguerite Brassac would undoubtedly have held a much higher position had not several electors considered her a copy of Charles Lefebvre.

The electors, curiously enough, consist of twelve amateurs and the same number of nurserymen, and a comparison of the

different sides will interest some of our readers.

I must not close this portion of my task without gratefully acknowledging the many kind letters of approval that I have received, and I desire also to thank heartily all those who have assisted by their lists to make this election successful. I trust it may interest some and prove useful to many.

I propose in our next to give the poll of the garden varieties.

Joseph Hinton, Warminster.

VINES IN POTS.

I HAVE read with very great pleasure Mr. Iggulden's able contribution on page 263, and I hope with great profit. It is the most practical paper on the subject I ever read. I feel indeed proud we have such a man in our ranks. Respecting cut-backs I quite agree with him, and hold it next to impossible to grow good ripened fruiting canes from eyes the same year. I am well aware of the great service done to us by the leading nurserymen, to whom we owe a debt of gratitude, still they cannot do impossibilities. I have just now sixty canes quite ripe and ready to begin forcing at once. They are all well top-dressed and pruned—two points of importance for early forcing. Mr. Iggulden gives sound advice when he says six bunches are ample to leave on each Vine. This is my practice except with Trebbiano, which comes magnificently in pots. I have had them 4 lbs. in weight, clear amber in colour, large berries, and really good in flavour.

With respect to turning the Vines out in a prepared border I feel sure Mr. Iggulden will forgive me for disagreeing with him. I turned out a dozen four years ago, and very much they pleased me until the Grapes arrived at the colouring point, when they did not finish satisfactorily. A gardener in this locality seeing my dozen turned out was so pleased with their good appearance that he turned out his whole stock the next year, and they behaved in a similar manner. I may say in conclusion, my two pot vineries are quite my two pets, and no houses here are more productive than they are. We generally commence cutting about the middle of April.—R. GILBERT,

Burchley Gardens.

WINTER-FLOWERING PLANTS.

The season is fast passing away with but few advantages for the general plant-grower. The year started with disadvantages, and instead of decreasing as the season advanced, as we generally expect them to, they have comparatively speaking increased. The summer is now gone, and autumn returned with no brighter prospect; sunless weather and cold nights still con-Growers that are short of warm pits have this year felt more than ever the need of them where abundance of flowers has to be produced through the winter months. Cold pits for some classes of plants have been almost useless. Poinsettias and Emphorbias of the later batches have never been in cold frames with us this season. The earlier batches through necessity had to be placed in them; their progress was unsatisfactory, and far benind what we should have anticipated in an ordimary season. Their growth is soft, nor are they so well fitted for producing large bracts as if the wood was in a more matured state. It is really necessary, especially in seasons \

like the past, to have heated houses or pits at command, where heat can be applied when deemed expedient before the roots receive a severe check, which is perceptible in the foliage, which soon turns yellow and finally falls off. It will be well for us here to say that when the above-mentioned plants are housed, caution must be exercised that the temperature is not kept too high. Plenty of air must circulate through the house, and should be kept in a much drier condition than is generally supposed to be good for the well-being of the plants. The external temperature has been unfit for bringing plants into a matured state for flowering, and unless artificial heat is employed the grower will fail with all other attempts to have a satisfactory return for the time and labour expended.

Euphorbia jacquinizeflors is frequently grown in too much heat. It will in ordinary seasons do well in cool frames for at least six weeks or two months, and when removed to warmer quarters should be brought on gradually. Grown close to the glass in a rather cool atmosphere it is an admirable plant for conservatory decoration. Its lovely brilliant orange-scarlet sprays with cool treatment are then much brighter. It is light and elegant, and stands out well when arranged amongst plants

of a stiff and dwarf nature.

Libonias have been free from insects this year, and have ade good bushy plants under cool treatment. This plant made good bushy plants under cool treatment. will not grow rapidly if subjected to too much artificial heat. Heat is advantageous in the early part of the plant's develop-ment, and a little warmth again in early autumn when the plants are removed from cold frames. The plant enjoys from this time a place near the glass where air circulates freely. The same remarks apply with equal force to the old but useful Sericographis Ghiesbreghtiana.

Young plants of Abutilous do not appear to be much affected by the season, for they already are showing abundance of bloom. We have concluded that these useful plants will succeed satisfactorily under very different conditions. Celosias and Cockscombs for early winter are now generally known; they not only last a considerable time for the decoration of the conservatory but are valuable for cutting purposes. The plants are in a very backward state, especially those sown late. must have a good brisk temperature to bring them forward as quickly as possible.

Begonias of the manicata and hydrocotylifolia types have this year been very unsatisfactory in cool pits; the damp dull weather has caused their leaves to decay. It has been an impossibility to keep the foliage dry, consequently where cold frames only have been at command the plants have lost many of their lower leaves.

B. parviflora, B. weltoniensis, and B. Ingramii are not so susceptible to damp as B. manicata. Of the three mentioned the continuous-blooming B. Ingramii is by far the best. For spring work few if any surpass B. mitida alba when true, and its beautiful rosy-pink form named roses. Scutellaria Mecciniana also does fairly well in cool quarters

during the summer when seasons are favourable, but we have not removed our plants this year out of heated pits. Limum trigynum has developed favourably; it appears to enjoy shade and a moist atmosphere while growing. This old favourite is very subject to red spider, which soon arrests its vigorous growth if timely measures are not adopted to destroy it.

Heliotropes and those useful plants Zonal Pelargoniums must be under cover in a light airy situation, where those intended for flowering next month can be assisted with a little heat. Plants that were out back during the summer and placed outside have not made much progress. If success is desired with these plants they must be encouraged for a time indoors.

Tea Roses intended for early forcing must have special attention in assisting to render the wood thoroughly matured, as it is in a backward state. The plants must be kept cool and the air about them dry. The earliest plants of Hybrid Perpetuals should now be under cover in a dry, airy, cool atmosphere for a time before pruning them back. We believe the new hybrids of Mr. Bennett will preve very valuable to lovers of Roses generally; we have formed a very high opinion of them. They are most floriferous, every small shoot producing a bloom, and they appear to continue flowering for a considerable time.

Imantophylium miniatum—If this plant was assisted with heat after flowering and then grown in a cool house it will now have its growth matured, and can be again pushed forward into flower with the assistance of heat. Home-grown Belladonna and Guernsey Lilies do not throw up their flower spikes so early as those from the Continent, but can be brought

forward as required from this date. They do well grown in pots or planted out. Heaths, such as Erica Wilmoreana and E. hyemalis, are in a very backward state in the north. The freer varieties, such as E. gracilis and E. melanthera, have not set so well as usual. Epacrises are in good condition, and will bloom well.

Azaleas are well set with prominent buds, while Camellias in many instances have but few flower buds. The season has been too moist and dull, especially at the time when the first growth was completed. The plants again started into growth at the expense of the flower. This second growth in established plants we endeavour to avoid by keeping the house drier and cooler after growth was completed, but all our efforts

this year have failed to prevent a second growth in many plants.

Calla æthiopica has thoroughly enjoyed this wet and cloudy season. Our plants are strong and even more vigorous than they were last year—a sufficient proof that it is unwise to subject them to that unnatural ordeal of drying. If not lifted and reported where the planting-out system is practised no time should be lost. Our plants are partially established in their pots, and some have already commenced producing strong spathes of flower. For room decoration this plant is indispensable.

Salvia Heeri and the bright rosy pink variety Salvia Bethelii should at once, where planted out, be transferred to pots and kept in a shady position until root-action has again commenced. Solanums have this year failed to set a berry outside with us and with many others in the north. Those only who grow the plants under glass and obtained a crop of berries before placing them outside have been successful.

The early batches of Mignonette will by this time have covered the trellises allotted to them, and will, if the plants were pinched a short time ago, have commenced to show a good and regular head of bloom, which will come in well when the plants outside are cut off by frost. These, as well as the early batch in 6-inch pots, should be placed in a light airy situation near the glass.

The hardier class of Rhododendrons, Ghent Azaleas, Deutzias, Plums, &c .- growers will this season see the advantages of growing under glass in early spring. Rhododendron præcox and R. multiflorum grown under glass in early vineries and Peach houses could now be brought into bloom with little

trouble.—W. BARDNEY.

ROOT-PRUNING.

So much has been written on this subject at different times that anything further seems only to exhaust a threadbare subject; nevertheless, as I am a strong advocate for root-pruning, and believe it to be the only means of inducing fertility in barren fruit trees, the few remarks which I now propose to advance shall be entirely based on my own experience. It has more than once appeared to me that the practice of rootpruning must sooner or later occupy a far higher and important position in the routine of the garden. Nearly all fruit trees come into a bearing state at some period of their existence, but in order to insure a fine crop of well-finished good-flavoured fruit year after year considerable attention and skill are required. The old system of cutting the young shoots back to one or two eyes in the winter, with the idea that it induces the production of flower buds, is, I think, very wrong. So long as the roots of fruit trees are allowed to roam, and subjected to no periodical restraints, so long will the trees remain more or less unfruitful, particularly so if they are encouraged by the annual spurring-back of the young wood. The last planting of fruit trees here was in 1871, principally Apples and Plums. Three years after being planted they came under my charge; they were then making strong growth, and apparently in good condition, but little fruit was produced. This being in the month of Septem-ber I thought I would wait a week or two longer; therefore the following month I examined their roots, which I found as straight and clean as possible, the trees being planted in deep pits concreted with yellow clay. We lifted them carefully with large balls, mixing the concrete with the soil, and replanted them near the surface, spreading about 2 inches depth of half-decayed stable manure over the surface of the ground. A fine crop of fruit was produced the following year, thus proving that root-pruning, if judiciously performed, need not be the means of sacrificing a crop, but the means of promoting one of greater weight and superior quality.

To be as brief as possible, and confine my remarks to what we practise here, I may add that the trees are all surface-

planted except an old orchard. Their roots are looked to every second year as soon as the fruit is gathered, and heavily mulched with manure, which remains on until the following autumn, when the rough portion is raked off and fresh material applied. The trees are pyramidal, averaging from 8 to 12 feet high, and produced good crops every year. This year they are all heavily laden, but, like all the productions of sunless 1879, the fruits are comparatively small. The following are a few of our varieties, all of which have borne heavy ing are a lew of our varieties, an of which have borne neary crops this year:—Apples: Lady Derby (Whorle Pippin, Winter Hawthornden, Norfolk Stone Pippin, Nelson Codlin, King of Apples (Warner's King), Lord Derby, Grenadier, Beauty of Kent, Packington's Summerington, Louis I., Normanton Wonder (Dumelow's Seedling), Oslin, Mère de Menage, King of the Pippina, Lady's Finger, Ringer, Rylance's Surprise (very large), Cellini, Sturmer Pippin, Pott's Seedling, Golden Spire, Lord Suffield, Keswick Codlin, Emperor Alexander, Golden Reinette, Blenheim Pippin, Golden Pippin, Small's Admirable, Devonshire Quarrenden, and Gloria Mundi. Plums: Victoria, Red Orleans, Jefferson's and Coe's Golden Drop.

"WYLD SAVAGE" at page 224 recalls to mind with pride those years in which he won first prizes at the metropolitan shows; and as I have had the pleasure of standing shoulder to shoulder with him, or rather our stands have been placed side by side at some of those shows, I felt regret at his non-appearance as an exhibitor during the past season. However, according to his present determination we hope to hear of his competing again, and I trust successfully too.

How envious must "WYLD SAVAGE" feel in reading "Current Topics," page 275, to find that Mr. C. P. Peach never sees green fly, an unhealthy shoot, or a mildewed one in his garden, and all prevented by winter mulching, proper pruning, and the avoidance of Dog Roses as stocks, especially the seed-ling Briar. Surely this will make "WYLD SAVAGE" and others hesitate before using the seedling Briar as a stock, when by the avoidance thereof they may escape so many ills the Rose is liable to. I for one should certainly feel grateful if Mr. C. P. Peach would supplement "Current Notes" with an article on his method of pruning Roses, as those grown on the Manetti are with me quite as virulently attacked with mildew as those on the seedling Briar; and as they all received a winter mulching my error must have been in the pruning, which was quite orthodox.—Oxonian.

THE ROYAL GARDENS, KEW.

THE official Report on the progress and condition of the Royal Gardens, Kew, during the year 1878 has at last been issued, but the interesting nature of its contents and the exhaustive manner in which they are treated amply compensate for its somewhat tardy appearance. Many of the subjects are of considerable importance to colonists, and the information conveyed in reference to them will be found of great value. The Coffee-leaf disease which has proved so disastrous in Ceylon is treated on, the fungus Hemileia vastatrix being described and illustrated by copies of the elaborate drawings which accompanied the Rev. R. Abbay's paper in the seventeenth volume of the Linnsean Society's Journal; the most important remedies are also referred to. Some instructive correspondence and remarks upon various materials that may be utilised in the manufacture of paper are included in the Report, and the plants specially noted for the purpose are the Bamboo, the Baobab, Yucca brevifolia, Eriophorum comosum, Molinia cærnlea, and the Trinidad Spear Grass. Indiarubber plants also receive a large share of attention. Mr. Mann's mode of cultivating Ficus elastica in Assam is detailed, the chief caoutchouc-yielding plants such as species of Alatonia, Hevea, and Castilloa are mentioned, and the successful cultivation of the two latter in Ceylon and India is described. Certain plants adapted for cultivation in tropical countries as fodder are indicated, especial attention being given to the Prickly Comfrey and the Grass Euchlæna luxurians. A full account of Cinchons cultivation in Ceylon and Jamaica is given, also particulars of the establishment of Liberian Coffee in Demerara, Ceylon, and

Singapore, with a variety of subjects of minor importance.

Respecting the work of the establishment in distributing and interchanging plants and seeds, the following significant statistics are submitted:—Received from 239 contributors, 4803 plants and 2337 packets of seeds; distributed 1365 packets of seeds, 7616 stove and greenhouse plants, 1202 herbaceous

plants, and 1584 trees and shrubs.

The number of visitors to the Gardens during 1878 was 725,422, being nearly 26,000 in excess of all previous years. The greatest week-day attendance was on August the 5th, when 57,121 persons visited the Gardens. The gates were opened at 10 A.M. on each of the bank holidays, but comparatively few persons appear to have availed themselves of the privilege, as on April the 22nd only 3352 were admitted before 1 P.M., out of a total for the day of 46,201. In reference to this Sir Joseph Hooker writes as follows:—"Considering the persistence and energy with which the movement for a daily early opening was pressed, I confess I am surprised at the small success which has attended the experiment. I am confirmed in my belief that the demand does not really correspond to any widely felt public want, and that the ordinary hour of opening is entirely adequate to the convenience and needs of metropolitan visitors; while I am more than ever convinced that the early opening would be highly prejudicial to the unique character of the Royal gardens as a place of public resort." The truth of these remarks will be readily admitted by all unprejudiced persons, and it would be a subject for regret that an establishment which renders such valuable services should be impeded in its working merely to satisfy a minority of interested local agitators.

NATIONAL ROSE SOCIETY.

A MEETING of the General Committee was held by permission of the Horticultural Club at their rooms, Arundel Street, on Tuesday, October 14th; R. G. N. Baker, Esq., in the chair. The Hon. Treasurer submitted his financial statement, from which it appeared that after paying all expenses there remained a balance in the bank of nearly £130. It was then resolved that the outstanding liabilities to prizewinners for the year 1877, which they had kindly allowed to remain over, should be paid; there would then remain a balance of £60 and the Society is entirely free of debt. It was proposed also that the London Exhibition should be held at the Crystal Palace, Sydenham, on July 8rd. An offer had been made by the Manchester Botanical Society that the provincial Exhibition should be held there again; but it was determined that it should be announced that, in order to give opportunities to other localities, the Committee would be willing to receive applications from any other towns which might be willing to receive the Society. It was announced that Mr. R. G. N. Baker would give a cup, value £10 10s., to be competed for by amateurs; Messrs. Paul & Sons a cup, value £10 10s., for Cheshunt-raised Roses; and the proprietors of the "Journal des Roses" a silver medal for twenty-four Roses, three of each, one full blown, another half blown, and the third a bud. Treasurer submitted his financial statement, from which it appeared

the third a bud.

The meeting was most cordial, and general satisfaction expressed at the prosperous condition of the Society.

AURICULA CULTURE.

A CORRESPONDENT in the midland counties who is just commencing the growth of the Auricula asks for some information. My observations will be simply intended for beginners, and I shall from time to time as the seasons advance give what directions I think necessary for their successful

cultivation.

My friend described to me the frame he had obtained to winter them in. It is one of those standing on legs, glass at the sides, and open at the bottom. He had had the frame made from a drawing he had seen in some book. These frames were at one time much used in the north. Now, although the Auricula does not dread frost so much as damp, yet I prefer a frame where they can be more snugly housed during the winter months, and for a beginner nothing can be better than an ordinary garden frame standing on a good deep bed of coal ashes in order to prevent the worms from getting into the pots; or a frame may be made about double the depth of the ordinary one, and shelves made of battens through which the water can run away. I have had them made with hinges, but I think it is better not to do so, and when air is to be admitted they can be tilted on the lee side, so that the water does not beat in; by this means, too, there is less fear of drip, which is one of the most fatal enemies of the Auricula. When the weather is cold and frosty a good piece of frigi domo should be laid on the frame, as although the Auricula plant is naturally alpine and will survive even if the soil be frozen hard, yet when the truss is formed in the heart of the plant frost is apt to injure the evenness of the bloom, and should therefore be avoided. I have seen them well grown in both ways, but for a beginner I I for sale and profit. The houses are lean-to's, and erected

think the ordinary frame is the best. As anyone beginning to grow them at this time of the year must procure plants from growers it will be needless now to give any directions as to the pots, their size, shape, &c. This will be better done in the spring, when the season for repotting arrives. The points to be observed now are to keep the pots free from weeds, to water only sparingly—I do not mean giving driblets at a time, but to give a good watering, carefully avoiding wetting the foliage, and then not to water again until the soil becomes dry; and, indeed, during the winter months they only require such applications of water as will keep the foliage from flagging. Anything short of this will suit them best. Should the surface of the soil become green it is best to stir it up with a blunt stick. Let slugs also be carefully looked for; they oftentimes get at the neck of a plant and eat away into the heart before any-thing is known of their presence. The presence of drip ought carefully to be guarded against; green fly, too, although not so troublesome in the winter months, is also injurious, and should be brushed off with a camel-hair brush. Air should be given at all times when it is possible to do so, but taking care to open the frame at the lee side so as to prevent rain from beating in and the cold wind from blowing on the foliage. By following these directions a small collection may safely be housed during the next three months, when first operations will have to be undertaken.—D., Deal.

GRAPES WITHOUT FIRE HEAT.

Your much-respected correspondent, Mr. Harrison Weir, says on page 285 that I am not correct in stating our Grapes says on page 263 that I am not correct in stands of whates were grown without fire heat. I think it is only right that I should say that I have never written about, shown, or represented any Grapes as being "grown" without fire heat, all I have said being they were "ripened" without fire heat. I do not suppose that any of your readers who might raise Cauliflower or Celery plants in heat, say in March, would think it

correct to term them forced vegetables if shown in August after growing in the open air from April or May.

I think Grapes which have no fire heat from the time the berries were visible until they were perfectly coloured may fairly lay claim to have been ripened without fire heat. I may say that under the same circumstances as the Black Hamburghs, Gros Colman and Barbarossa have acquired a perfect colour. I do not mean to say that it would be well to have all vineries without any means of heating them, but I daresay there are many growers who would gladly do with less fire heat than

they employ at times.

Respecting excesses of heat, I may say that I think there are great mistakes in the advice so frequently given about Orange trees. This bad season the Orange trees here have stood in the open air since the middle of May; many of them have ripened fruit, and at the present time (October 14th), pecks of fresh fragrant blossom could be gathered, although the night temperature often falls to 35°.—J. MUIR.

THE discussion on ripening and colouring Grapes in unheated houses—initiated by Mr. Muir, and the feasibility of which during such a sunless season as has passed has been discussed by other correspondents—is of great practical utility. Can good, fairly sized, and well-flavoured Grapes be obtained without fire heat under such circumstances? I am in a position to say Yes, decidedly, even in Ireland, which cannot boast of such a genial climate as in the southern counties of England. Yesterday I was invited to taste Black Hamburghs grown in a lean-to house with a south-west aspect, in which there has never been even a heating apparatus, by Mr. Ryan, of the firm of Boyd & Ryan of this town, and better-flavoured Hamburghs I have rarely tasted. I was assured they have been cutting for some time, and a considerable crop still remained. Is this result possible generally? and if not, why not? Remembering that the application of fire heat is the rule to complete the ripening and colouring this year, and not the exception, the answer to those questions is very important when one considers the additional labour and expense.

Before giving what I consider the secret of Mr. Ryan's exceptional success I may appropriately refer to the large vineries of one of the merchant princes of Waterford (Henry White, Esq.), recently visited by a gardening friend and my-self, from this point of view. Two of the largest are perhaps 50 yards long, and have been erected from designs by the Messrs. White, and entirely with the view of growing Grapes

with the special object of catching every ray of sunlight. As | early Grapes are required, and the warm sunlight did not come, recourse was had to fire heat, and in the vineries referred to the middle of last month, about £11 had been expended in coal, with collateral additional expense for attendance. attendance and cost of water was reduced to a minimum, owing to all the rain water of the structures, and it was considerable this year, being collected in a large cistern and pumped as required by a windmill adjacent, erected from plans of those intelligent gentlemen. As I have not seen anything of the kind in Ireland for a like purpose I digress to note its perfect success, cheapness, and feasibility. Of course, growing Grapes for such a purpose, the expense referred to for coal, &c., will lessen the profits; but it seemed unavoidable, especially as some of the Vines—such as Lady Downe's, Gros Colman, and West's St. Peter's—would be slow to ripen or colour under the most favourable circumstances without fire heat. Some of the bunches of Gros Colman were little inferior to those shown at the Exhibition at Paris last year, and highly flavoured. The system of growing is from single eyes, but I must not further digress from the subject.

Three things seemed to favour the ripening of Mr. Ryan's Grapes:—1, The soil and subsoil; 2, The absence of plants in the vinery; and 3, A plain-washed back wall. I have just space to say a word on each. 1, Clonmel is built on a sandy shingly formation that enables the soil and subsoil to part readily with superfluous moisture, and this applies here. The soil for the roots to grow in is consequently always dry, and the relative temperature on that account higher, especially, as in this instance, when properly prepared. 2, I know several crops of Grapes utterly ruined where employers insist on having large foliage and other plants is vineries. Success would seem impossible without fire heat in such cases, and extreme care in ventilation besides. 3, The reflected rays of heat from a whitewashed back wall would seem to deserve more consideration. If Mr. Ryan can ripen Grapes on a small scale, and without any exceptional treatment or advantage, why cannot others on a larger scale?—W. J. M., Clonmel.

EARLY CHRYSANTHEMUMS AT SLOUGH.

Some extremely bright beds of dwarf Chrysanthemums have, for more than a month past, been the most attractive feature in Mr. Turner's nurseries. The varieties are planted in rows white, pink, yellow, maroon, rosy purple, &c., and have produced an extremely gay appearance, and the flowers have been most valuable for cutting. These cheerful beds suggest the usefulness of early-flowering Chrysanthemums for gardens generally, and not less so for public parks, both metropolitan and provincial, where flowers are cultivated. Especially during the past two or three years Pelargoniums have been of disappointingly short duration, and for nearly two months in late summer and early autumn many parks and gardens have been com-paratively flowerless. In Battersea Park one row of a white Chrysanthemum has for a month past produced more flowers than all the rest of the beds and borders put together; but brighter and richer colours are much wanted, and there is no difficulty whatever in producing them.

Barly-flowering Chrysanthemums are also equally useful for conservatory and greenhouse decoration during September and October, and when well grown they impart a fresh and bright appearance to the structures just at a time when many plants —Petangoniums, Fuchsias, Achimenea, &c., have a seedy or worn appearance. But when the plants are intended to be flowered in pots they should not be grown in them throughout the season, but should be planted out in good soil and an open position, and be lifted and potted when the flower buds are fairly visible. If grown in pots in the summer premature flowering is often induced, and the plants are sometimes "scrubby," but when planted out they grow freely, producing good foliage and numerous excellent flowers. No plants lift better than these do, for, due care being exercised, they scarcely lose a leaf.

A great advantage possessed by these plants over many others for border cultivation is that they are seldom eaten by slugs—a point of no slight importance during a season like the present, when those pests have been so generally destructive. Sings will eat Chrysanthemums it is true, but not voraciously; they are amongst the last dishes of the molluscs and are only partaken of when other food is scarce. This remark applies to plants grown in borders, as cuttings of Chrysanthemums raised tenderly in heat in the spring are often provokingly

nibbled off, but even then a few young Lettuces or African Marigolds would be preferred by the slugs.

For the reasons stated and for the purposes named this early ppe of Chrysanthemums is worthy of much more attention than it generally receives, and by adding the best varieties of the section to the later incurved and Japanese varieties Chrysanthemums may be had in plenty for upwards of four months.

A few of the best and most distinct of those that have been for some time so attractive in the beds at Slough are the following:

Yellow.—Précocité.—Flower of medium size; florets slightly incurved, bright yellow; very floriferous. Jardin des Plantes.

—Very early; florets pale straw colour. Andromeda.—Similar to Précocité, but lighter in colour. Gold Button.—Flowers small but neat; florets pale yellow when fully open. Hendersonii.—Flower rather larger and fuller than the last; florets a fine bronze yellow.

WHITE.—Jardin des Plantes.—Flowers large; florets pure white. Nanum.—Flowers large and full; florets creamy white;

valuable for cutting.

Pink.—Cassy.—Flower of medium size but good substance; florets pink. Madame Pecaul.—Flowers large and full; florets

incurved, purplish lake.

Maroon.—Frederick Pélé.—Flowers of medium size; florets light maroon or chestnut colour; effective.—J. W.

MAGNUM BONUM POTATO.

MR. WARREN has given the results of his trials with samples of this Potato which he obtained under two different names; but he does not state that he obtained Suttons' Magnum Bonum direct from Reading nor Carter's Magnum Bonum direct from Holborn. After considerable experience with new vegetables sent out by different firms I have found it important to procure varieties to which vendors' names are prefixed direct from these who select the varieties and adopt them as their own, for they then take care to select good stocks so as to maintain their reputation. A mere name attached to a Potato will not affect its growth, but good soil and culture, with careful selection and management of the "seed," will do so; commequently those dealers who have "specialities" to dispose of adopt the measures necessary for producing them in the best form and condition.

I remember when Suttons' Redskin Flourball was introduced ebtaining a small supply from Reading. The produce was carefully preserved and prepared for planting. The following year more seed was had from Reading and the same quantity of "Carter's Improved" Redskin Flourball from Holbert. Suttons', Carter's, and my own home-raised stocks were planted together. There was practically no difference in the crops obtained from the purchased seed, but "Carter's" selection grew rather the stronger of the two, yet the growth resulting from my own carefully chosen and prepared seed, and also the crop produced, were clearly different—the growth being stronger throughout and the crop heavier. The following year the three "varieties" were kept separate, the seed of each being selected and stored with care, and at digging time there was absolutely no difference in growth or crop, the three having merged into one variety. After that they were mixed and grown for the pigs, for the soil did not produce them fit for the table. They continued to be grown, the seed neither being selected with special care nor stored in a special manner. The crops appeared to get worse yearly, and the variety to degenerate, until it was discarded. So much for names and "specialities," and the importance of selecting and carefully

preparing the seed.
Since Magnum Bonum has achieved such a high reputation it would be well if it could be stated to whom the credit is due of having raised the variety.—AN OLD GROWER.

I NOTE a letter in your paper contrasting the yield, &c., of some Magnum Bonum Potatoes from Suttons' and Carter's. It'so happened that I grew Carters' Magnum Bonum Potatoes for two years running, and I was much struck with their superior qualities both as to yield and more particularly their free-dom from disease. I remember that on the last year I had one plot of Potatoes near to them which were badly diseased, while Carter's Magnum Bonums had no trace of it, and it was for these reasons that I thought them so suitable for garden cultivation. I do not think much reliance can be placed on a small isolated experiment such as has been mentioned as to the quality between two rival seed-growers, the result of which

may have been affected more or less by various circumstances which we are all, perhaps, familiar with, and more particularly during such a season as we have had. No doubt Suttons' things, from the high name they carry, are excellent; but if their Magnum Bonums will really on a full trial give better results than Carter's it would be a wonderful Potato.—FRANCIS FRANCIS.

IF your correspondent Mr. Warren had purchased his seed of Messrs. Carter & Co., of the stock I grew last year expressly for that firm, he could not but have been convinced of the superiority of the variety. As was published last year, I took 117 sacks off two acres of farm land after barley once ploughed, the tubers being as clean and as handsome as Snowflakes. The small ones from the above stock were sold to a man in the village, who retailed them to the poor around, and they have this year a marvellous crop: where all others are quite de-stroyed by disease these are all sound and good. Mine are equally sound .- CHARLES PENNY, The Gardens, Sandringham.

[We have several other communications on this subject, some advocating the merits of Messrs. Suttons variety and others that of Messrs. Carter. We see no benefit to be derived from the publication of either of them, and we must decline to occupy our pages with discussions on the "stocks" of rival tradesmen.—EDS.]

. NOTES AND GLEANINGS.

THE summer now drawing to its close will be memorable for the extremely low temperature that has prevailed, for heavy storms causing serious inundations, and for showers rather than sunshine occurring between the storms. Under such conditions many crops have grown freely, but those which have been grown for PRODUCING SEED have in the great majority of instances proved little less than total failures. Even the grain harvest is not yet secured, and much corn cannot now ripen. Anticipating what must inevitably follow -a great scarcity and consequently higher value of various garden and farm seeds, the London Wholesale Seed Trade Association have with good reason found it desirable to direct attention to the general and almost complete failure of many important seed crops, enumerating wrinkled Peas, Cauliflower, Carrot, ridge Cucumber, Leek, Lettuce, Onion, Mangold Wurtzel, and Scotch Turnip. We knew from experience and observation of the growing crops in various districts of this country how great the failure must be. The loss incurred by the growers must be very serious, and merchants must experience extreme difficulty in procuring supplies. Seed of the sest and most popular varieties of vegetables cannot be obtained from the Continent, for those varieties are not grown there in any considerable quantity; and if they were, the unpropitious weather that has to a great extent prevailed in continental seed-growing districts must have seriously affected the crops. It may be stated with a considerable amount of confidence, that no season during the present generation has proved so disastrous to seed-growers as the present one, and no one, on reflection, can justly complain if prices for many garden and farm seeds for next year are not markedly higher than the usual quotations.

- A CORRESPONDENT, referring to the POTATO CROP near PETERBOROUGH, observes that Early Rose has been the best cropper, with about 40 per cent. diseased; the worst has been the Scotch Regent, nearly all bad. Schoolmaster, Porter's Excelsior, King of Potatoes, and Aylesbury Kidney produced good but not heavy crops, and about 20 per cent. bad. All field crops in the neighbourhood are very much diseased, and the yield below the usual average.

THE following CHRYSANTHEMUM SOCIETIES will hold their annual Exhibitions on the dates annexed :- Birmingham, November 26-27; Hackney, at the Royal Aquarium, West-minster, November 19-20; Brixton, November 13-14; Southampton, November 18-19.

- In the LARGE VINERY at Chiswick the Vines are bearing a good crop of Grapes, that have by judicious management coloured and ripened well despite the unfavourable weather that has prevailed.

- ALTHOUGH it is surprising how green and fresh the foliage remains upon many trees in the vicinity of London, yet

which at Kew are now bright with the varied tints of yellow and crimson. Leucothoe racemosa and L. coriacea also add considerably to the beauty of our shrubberies, the leaves of the former becoming bright scarlet, and the latter a somewhat duller shade.

- THE Rev. W. F. Radclyffe has communicated the following note relative to Roses to the Dorset County Chronicle. "The first bloom was the finest I have had in twenty-seven years both for size and quantity. The plants bloomed more freely than I ever knew them to do, which is extraordinary, as we have had no sun. They then dropped all their foliage, and have now produced more, but too late for much effect. found over two hundred Roses had their roots much decayed by the continuous rains without heat or evaporation. I have bought 244 to supply their places to-day (October 8th), at the Dorset Nurseries. They are good plants and do Mr. Blandford great credit.'

A GOOD stock of DWARF SCABIOUS in pots would be found of great value for conservatory decoration in late autumn, also as yielding a supply of flowers for cutting at a season when there is not much variety. A number are grown at Gunnersbury Park for these purposes with satisfactory results.

DURING a recent visit to the well-kept gardens attached to GUNNERSBURY HOUSE we noticed an extremely fine specimen of Cycas revoluta, which for symmetry and healthy vigour can scarcely be surpassed. This is an important addition to the handsome plants with which the intelligent gardener, Mr. Hudson, obtained such high honours at several London exhibitions during the past season. The general health of the plants is remarkable, partly owing no doubt to the care Mr. Hudson exercises in preventing the ravages of insects. The Peach trees, &c., are occasionally syringed with water in which a bag of soot has been suspended, and the good effects of the practice are evident in the dark green healthy foliage. A new Vine border there has a concrete bottom, over which transverse rows of ordinary drain pipes are closely placed, com-municating with an outfall in front. This method enables the air to circulate beneath the border, and also permits all superfluous moisture to escape freely.

MR. R. IRWIN LYNCH, late Superintendent of the most important department in the Royal Gardens, Kew, has been appointed Curator of the University Botanic Garden, Cambridge, and he enters on his duties there this day (Thursday). Mr. Lynch has an extensive scientific knowledge of plants, and is also a skilled cultivator. By his diligence he has fitted himself for the position he now occupies, and by his general deportment has commanded the respect of his colleagues and coadjutors in the celebrated gardens in which he has been employed so long and successfully.

— We have received flowers of a new Violet from Mr. George Lee of Clevedon. The leaf resembles that of the common V. odorata, and the perfume is, if possible, even more intense than that sweet Violet. The colour of the new variety is blush veined and suffused with lilac, and it is named "argenteaflora." The flowers are single, half an inch in diameter, and the flower stalks 6 inches in length. Mr. Lee describes it as a profuse and continuous bloomer, the flowers in winter being nearly white and larger than those produced now. hardiness, freedom, and charming and distinct colour of this variety, together with its delightful perfume, must render it a great favourite and a valuable acquisition.

- The meetings of the Linhman Society during 1879–80 will be held on the following dates:—November 6th and 20th; December 4th and 18th; January 15th; February 5th and 10th; March 4th and 18th; April 1st and 15th; May 6th and 24th; June 3rd and 17th. The chair will be taken at 8 P.M. on each occasion, except on May 24th, the anniversary meeting, when 3 P.M. is the appointed hour.

IT has been decided to CLOSE THE HAILSTORM RELIEF FUND on November 2nd, and it is the desire of the Committee that any subscriptions not yet sent in may be remitted without delay. At a meeting of the Committee held on the 14th inst. the sum of £800 was voted for relief purposes on the recommendation of the Investigation Committees. When these were appointed, the Executive Committee, finding that the subscriptions announced represented but a fifth part of the aggregate amount of losses sent in by sufferers, instructed the Investigation Committees to confine their labours to ascersome are fast assuming their autumnal tints, and impart a seasonable beauty to our gardens. One of the most attractive mending the most deserving and necessitous cases. These trees in autumn is LIQUIDAMBAR STYRACIFLUA, specimens of returns having been made, were duly considered in Committee,

and the sum above named was voted. The aggregate quantity of broken glass was found to be very large, and as the amount at the disposal of the Committee would not admit of relief being administered according to a uniform scale, it was resolved to divide the applicants into three classes according to their needs, the most necessitous to receive 3d. per foot, the next 2d. per foot, and the least needy 1d. per foot. Already all applicants classed as necessitous have been relieved, and the remainder of the sum voted will shortly be awarded. remaining over at the close of the fund will be further distributed pro rata among the sufferers, as in the case of the Hailstorm Fund of 1876. A balance sheet will then be struck, and the Committee will bring their labours to a close.

- THE October number of the "Journal des Roses" contains a plate and description of the fine old Rose BARONNE PREVOST, accompanied by the following history:—"The little village of Yebles, in the Canton of Mormant (Seine et Marne), is the birthplace of the Rose Baronne Prevost, where it was raised by the celebrated Desprez, who dedicated it to the sister of his friend M. Guenon, the great raiser of Dahlias at Voise-non, near Melun. On the 27th of July, 1841, M. Desprez disposed of this valuable acquisition to M. Cochet, sen., for 100 francs, and it was sent out by the latter in the autumn of 1842."

— Mr. L. Pointon, foreman to Mr. J. Sherratt, Knypersley Nursery, has been appointed gardener to R. Heath, Esq., M.P., Biddulph Grange, near Congleton.

— WE have received the second edition of "NOTES ON LILIES AND THEIR CULTURE," by Dr. Wallace, which contains a very large amount of valuable information in relation to those beautiful plants. It is in a great measure a compilation of the writings of numerous English and American authors, whose papers have appeared from time to time in the horti-cultural periodicals, revised by Dr. Wallace, who has also con-tributed several chapters. The nomenclature is generally accurate, and the cultural instructions reliable. The names of species and varieties are spelled throughout the work with capital initial letters—a practice which is by no means general or desirable; and sundry little inaccuracies in orthography are noticeable, such as Burbridge for Burbidge, Batemannii for Batemannie, Chaiixii for Chaixii, &c. The illustrations are numerous and represent all the principal Lilies and the most distinct bulb forms, the latter having been originally drawn by Mr. F. W. Burbidge. The book will prove very useful to amateurs and others engaged in the cultivation of this attractive class of plants.

SEASONABLE NOTES.

AT the beginning of the winter season it may be profitable to be reminded of the requirements of some commonly grown and indispensable plants. Much depends on the plant houses, whether they are watertight, light, and airy, or not; and also the treatment the plants may have received during the past months. Plants which grow well out of doors during the summer months, if expected to continue growing or to flower throughout the winter, will in many instances require artificial heat. For instance, Bouvardies which have been planted out during summer are now coming freely into flower in a pit with a temperature of 50° to 55°, but later on they will stop flowering unless a higher temperature is given them. Winter and spring-flowering Begonias, which have also grown out of doors till lately, will shortly require a stove temperature. To Calla sethiopica, Geraniums, Carnations, Pelargoniums, Cyclamens, and Primulas the same remarks apply. In a new and light vinery I have, amongst other plants, some young Pelargoniums for winter flowering; these are coming on slowly and sturdily with abundant ventilation, and a little heat when necessary, whilst in other old-fashioned structures a fire is necessary to prevent the trusses damping off. There are other plants which do not require artificial heat to any extent, such as the pretty and useful Eupstoriums, Camellias which have been brought on early, Roman Hyacinths, and other early-flowering bulbs. Chrysanthemums in damp dull weather may in many places require a fire pretty constantly to keep the flowers dry. but in all these cases the less artificial heat employed the better.

Of more importance than flowering plants in many gardens is wintering store plants, either as young-rooted cuttings or old plants. Last winter showed up the weak points of the winter treatment of Ageratums, Verbenas, and Iresines. It cannot be too fully impressed on those who have a stock of these plants to winter that they must be kept growing, though ever so

slowly. Unless there is a certain amount of root-action induced by keeping the soil in a moist state, and the atmosphere of the house at a temperature to allow the leaves to perform their functions properly, there is very little likelihood of the plants wintering safely. Some of the tender Carnations, such as Souvenir de la Malmaison, require to be kept growing throughout the winter. Calceolarias, Violas, Pentstemons, and other hardy florist flowers cannot be kept too cool, Intermediate Stocks perhaps excepted.—R. P. B.

ACANTHACEOUS PLANTS FOR WINTER FLOWERING.—No. 4. ERANTHEMUM.

An extensive genus, chiefly characterised by its salver-shaped corolla, unequally lobed limb, and two fertile stamens. It contains a great number of very fine ornaments for the stove. Though freely interpreted the name signifies Spring Flowers, or Flowers of Spring, we have nevertheless a considerable number of species which put forth their flowers and gladden our hearts with their beauties during the dullest and dreariest days of winter. They are all very free-growing plants, are easily struck from cuttings, and should be renewed annually. Pot in leaf mould, peat, loam, and sand; drain well, and supply liberally with water. Frequent use of the syringe will be necessary through the summer to keep down red spider.

Branthemum Andersonii.—A somewhat sparingly branched shrub. Leaves oblong lanceolate and obtusely acuminate, 6 to 9 inches or more long, rich bright green on the upper side, paler below. Flowers produced in fascicles on erect terminal spikes, which are about the same length as the leaves. Corolla tubular; limb spreading, white; the middle lower lobe pro-fusely sprinkled with purple. It blooms during November and

December. Native of the East Indies.

E. aspersum.—This is frequently to be found under the erroneous name of E. asperum. It is a very distinct and beautiful species, although evidently allied to E. Cooperi and E. tuberculatum. The stems are somewhat obtusely fourangled and much branched. Leaves ovate and bluntly acuminate, waved at the margins, about 3 inches long, deep green on the upper side, paler beneath. Flowers arranged in a rather loose terminal fascicle. Corolla tubular, very slender, upwards of 2 inches long, white; limb unequally five-lobed, flat, upwards of an inch in diameter; upper lobes white, freckled with purple; lower one, which is largest, intense deep purple at the base; the margin white, sprinkled with purple dots. It blooms during February and March. Native of the Solomon Islands.

E. hypocrateriforme.—The present species is perhaps one of the very handsomest in the whole genus. It, however, is scarcely a winter-blooming kind, we having never seen it in flower earlier than April. It is a somewhat robust-growing plant, with four-angled stems and branches. Leaves opposite, ovate, obtusely acuminate, coriaceous, about 3 inches long, deep green on the upper side, lighter below. Flowers produced upon the apex of the shoots in a dense spike, with two additional axillary spikes at the base, forming a large spreading head. Corolla tube slender, slightly bent, more than an inchin length; limb spreading, about the same width as the length of corolla, bright red, which becomes more intense towards the base, where the lobes are all spotted with black, the reverse side being a pale sulphurous yellow. Native of Sierra Leone.

E. lawistorum.—Another very fine species from the Fiji Islands, where it is said to attain a height of 4 feet and upwards. It, however, flowers abundantly with us when about 18 inches. Leaves opposite, oblong ovate, bluntly acuminate, 4 to 8 inches long and 2 to 5 inches broad, the upper leaves being the smallest, deep green above, paler beneath. Flowers produced in axillary fascicles in great profusion. Corolla tube long and cylindrical; limb five-lobed, spreading, upwards of an inch in diameter, intense rich deep purple in colour; stamens exserted, the yellow recurved anthers affording a pleasing con-

trast. It blooms during November and December.

E. oronulatum grandiflorum.—A very variable species, the present form being a most desirable one. It is a free-growing plant of moderate size. Leaves ovate acuminate, 3 to 6 inches long, bright green. Racemes terminal, longer than the leaves, erect. Corolla funnel-shaped, nearly 2 inches long; tube white; limb rosy lilac. It blooms during midwinter. Widely distributed throughout India.

E. palatiforum.—Of this species there are two varieties, one having the limb bright scarlet with a yellow spot at the base of the lower lobe; the other soft lilac, with the same yellow

spot as in the scarlet-flowered form. The leaves are some spot as in the scarlet-flowered form. The leaves are some 6 inches long, lanceolate and blunt-pointed, deep green, irregularly blotched with creamy white. The same variegation obtains in both varieties, so that those who, ve variegated leaves have a double enjoyment in this plant. I blooms during March and April. Native of Silhet.

E. twberculatum.—A beautifully delicate and ornamental plant. It forms a much-branched compact little shrub, the stems and branches being covered with small tubercles and

stems and branches being covered with small tubercles and

clothed with a profusion of small sub-ovate dark green leaves, which are slightly notched at the apex. Flowers erect, solitary, axillary. Corolla tubular, slightly bent, very slender, white; limb flat, an inch in diameter, five-lobed, pure white. The erect flowers are so freely produced as almost to conceal the foliage and give the plant the appearance of a snowflake. It blooms during the early spring months. Native of the South Sea Ialands?

E. cinacharinum.—This is a somewhat lax-growing plant,

and therefore strict attention must be given in the matter of and therefore strict attention must be given in the matter or pinching and stopping in order to produce a well-furnished plant. Leaves oblong lanceclate and acuminate, with just the slightest pubeacence on both sides; the upper side deep green, paler below. There is a variety of this plant called occillatum, in which the leaves are irregularly spotted with creamy white. Racemes terminal, with the flowers all turned the same way. Corolla tube slender, shout an inch long and nale red in colour: Corolla tube alender, about an inch long and pale red in colour; limb flat, nearly 1½ inch in diameter, deep cinnabar red, with a small white eye and deep blood red blotch at the base of the lower lobe. It blooms during the spring months. Native of Burmah.

E. Cooperi (fig. 35).—This is usually considered a summer-flowering species, but we have had it bloom beautifully during March and April; indeed with a little management it may be had in bloom all the year round. It is a very free-branching compact-growing plant. Leaves 3 to 5 inches long, narrowly lanceolate, with deeply lobed margins, deep green above, much paler below. Flowers produced in pairs from the axils of the leaves. Tube of corolla slender, upwards of an inch long, white; limb five-lobed, all white saving the central lower one, which is beautifully marked with lines of purple dots. Native of New Caledonia. of New Caledonia.

E. pulchellum. - A very old inhabitant of our plant houses,

discarded long ago by the older gardeners and amateurs to make room for novelties, and now scarcely known by many young gardeners. Yet whenever seen the brilliant blue flowers rivet the attention of every beholder; and being a winter-flowering plant we would fain induce our readers to take it in hand, grow it well, and they will find it one of the most brilliant ornaments of the stove. If not carefully tended in the matter of stopping it is apt to become rather straggling; but as every shoot produces a large terminal spike of flowers, the more shoots produced the greater the effect. Leaves petiolate, broadly ovate, tapering to a blunt point; the surface somewhat bullate, intense dark green above, paler beneath. Spikes terminal with imbricate bracts. Flowers tubular, with a flat limb, which is rich vivid blue in colour. It blooms during December, January, and February. Native of the East Indies.

BLACK PRINCE STRAWBERRY.

I THINK it is not the first time I have written favourably of this Strawberry. Some growers and writers, if they can only obtain a few monstrous fruit on any other variety, evidently think it right to condemn Black Prince as producing fruit of only medium size; but I venture to say we have had a greater weight of fruit from this variety both in pots and planted out than it would be possible to obtain from any other. It produces fruit in masses, and in such a season as this it not only ripens earlier than any other but was more satisfactory altogether. It produces fruit freely under any circumstances or at all times, and it might be had in fruit every month of the year. We have the same plants in pots bearing ripe fruit now as we gathered from in the months of March and April last, I sometimes hear amateurs complain that their Strawberry plants produce plenty of leaves but no fruit. Such a complaint would never be heard of if Black Prince was more grown.—A KITCHEN GARDENEER.

SHEFFIELD GARDENS AND GARDENERS.—No. 2.

As previously intimated no attempt will be made in these notes to give elaborate details of the gardens visited, but only their general character will be glanced at, briefly recording anything specially noteworthy or suggestive of being useful. There is something to be learned from every garden large or small—some point of practice the success of which proves its worth, or some example of a contrary nature that is certainly not less useful to note as something not worthy of adoption. The gardens will be referred to much in the order in which they were visited, commencing with

THORNBURY.

Situated in a very commanding position is this, the residence of F. T. Mappin, Esq., a gentleman who has filled the highest municipal offices and been a benefactor to the town. Being nearly on the summit of a hill of considerable altitude the mansion overlooks a most picturesque valley, from which the hills beyond rise and recede until they vanish into azure-tinted curves. The grounds are on a steep hillside, so steep that the drive takes a long detour, and even then the mansion is not reached except through a rather deep "cutting." The middle of the drive only is gravelled—about 2 feet of the sides being of asphalt for accelerating the outflow of the water that, during storms, rushes from the higher ground with a force that no gravel could resist. The grounds were "laid out" by Mr. Marnock, who has executed his work admirably. There is much that is artificial, but the mere artificiality is almost lost by the close manner in which Nature has been followed; and the result is a few acres of pleasure grounds highly worthy of the name. A lawn of considerable extent and agreeably undulated contains large beds of shrubs and marginal mounds, and this fine lawn is not broken up into patches by narrow gravel walks.

Nowhere in the district is such a fine collection of shrubs, interspersed with Conifers and relieved by fine old Oaks, to be seen as at Thornbury; indeed in few places are evergreens found in better order. That Conifers thrive so well is proof the air is not impure, and the condition of the entire collection manifests that the specimens are much valued by the owner, and managed with care and skill by the gardener. Every shrub, and there are many hundreds, is a handsome specimen, or being formed into one, each apparently receiving the same care as if it were a specimen plant being prepared

for exhibition. No approach to crowding is permitted; the requisite amount of pruning is done to maintain symmetry without undue formality, and the borders are manured to keep the specimens in the rich colour indicative of good health. Nearly all kinds of shrubs are represented; but Portugal Laurels predominate, and fine they are. Conifers are also numerous, the specimens of Cupressus virginiana being particularly handsome, as also are several varieties of C. Lawsoniana. Cryptomerias thrive fairly well, but Wellingtonias make rather slow progress, the soil not being sufficiently deep to afford them the sustenance they require. Some of the Pinuses a year or two ago assumed an unhealthy aspect; growth ceased, the foliage turned brown, and much concern was felt respecting them. On examination their roots were found to be infested with a fungus. The gardener at once had the soil removed from them as much as possible, gave them a heavy dressing of freshly slaked lime, and replaced the soil. The effect was magical; the fungus was destroyed, growth commenced, and the specimens were saved. The remedy so promptly applied and so successful merits record; and the mode of shrub culture practised

is worthy of more general adoption.

I pass on to note one or two mistakes, not greatly felt at Thornbury perhaps, still they may be mentioned. They are not, however, in the flower garden—a terrace where carpet bedding is very well done; nor in the conservatory, a capacious structure erected by Messenger, in which all the plants look well, including those in an enjoyable tropical section; nor in the vineries, where useful crops of Grapes are produced; nor in a structure devoted to Tomatoes, where a splendid crop of in a structure devoted to Tomatoes, where a spientid crop of Vick's Criterion is ripening; nor amongst plants generally, for Camellias, Azaleas, &c., look well, as do the Orchids, especially Stanhopeas and a fine flowering specimen of Renanthera coccines, also grand examples of a superior variety of Imantophyllum. For the first mistake made we must pass to a Peach house, where on a narrow border in which the trees were planted a rockery has been formed and planted with Ferns. The two Peach trees have never flourished since, and in the event of their decay a third tree has been planted beyond the rockery and its stem bent over it to the wall. This tree is growing freely, so it is plain that large stones placed over the roots of Peach trees do not form a good "top-dressing." The next mistake is more important—it is erecting a fine curvilinear span-roofed house on the Cranston principle, and planting it with Peaches and Nectarines, and not providing any means of heating it when necessary. In ordinary seasons the fruit may ripen, but during a summer like the one just closed it cannot do so, nor can the wood become matured. A few Pear trees near one end of the house are ripening their crops well, and suggest that if half the house had been planted with Pears the structure would be more useful. In the case indicased local obstacles prevented the piping in other structures being extended round this fine Peach house, where hundreds of fruit remain hard, and even if a few of them ripen they must be very deficient in flavour. The lesson deducible from this failure is never to erect a house of this nature for Peaches, in cold localities especially, without providing the means for ripening the crops.

The kitchen garden is small and well cropped, the reserve ground containing a fine stock of hardy plants for the ornamentation of the terrace flower garden in spring; but most of the vegetables are grown in other gardens at some distance

from the mansion.

The gardens at Thornbury are thoroughly well managed by Mr. W. K. Woodcock, a skilled and industrious gardener, and a very useful man in the district, as it is his pleasure to endeavour to foster the advancement of horticulture and other worthy objects.

OAKBROOK.

By his princely munificence the owner of Oakbrook, Mark Firth, Esq., has had the distinguished honour of entertaining Royalty on more than one occasion. Four years ago the Prince and Princess of Wales were Mr. Firth's guests on the opening of Firth Park. Last year the Crown Prince of Sweden visited Oakbrook, and during the present week Prince Leopold was entertained there on the occasion of his opening the new University Buildings which Mr. Firth has erected and presented to the town.

It appears to be the custom of Royal personages to leave mementos of their visits to Oakbrook by planting shrubs on the lawn. The Prince and Princess of Wales planted four of Fisher's Golden Irish Yews, the Crown Prince of Sweden a Golden Queen Holly, and probably Prince Leopold has followed the practice of his predecessors, so that Mr. Firth will soon have quite a collection of Royal shrubs. The Golden Irish Yews referred to are probably the finest specimens of their kind in any private garden. They were planted on well-prepared stations, and have grown in the most satisfactory manner. They now exceed 6 feet in height and are well furnished, and surpass the specimens mear the grand conservatory at Chatsworth. This Yew, which originated in the Hundsworth Nurseries, will prove a fine object on lawns. It appears to grow as freely as the normal green species, while nearly every leaf is margined with yellow, and the specimens when associated with evergreens resemble pillars of gold.

Oakbrook presumably derives its name from the Oak woods that no long time ago covered this almost ruggedly undulated district, and the watercourse which rushes down the valley. Many trees still remain clothing the sides of the hills and even the summits of some of them, making the delis appear deeper and richer in their mantle of foliage. Atthough almost within rifle shot of the smoky town the scenery here partakes of a wild natural grandeur, reminding one of a fine view in Scotland.

Mr. Firth appears to have been satisfied with Nature's works,

Mr. Firth appears to have been satisfied with Nature's works, and has not indulged in many artistic touches in the adornment of his grounds. There is very little flower gardening, and plants are only grown under glass for ordinary decorative purposes and for supplying flowers for cutting. Fruit is more in request, and Mr. Hail, the gardener, is making preparations to meet the demand. New Vine borders have been made, and the young Vines are bearing good occus and give promise of producing better. Golden Queen is time in banch and berry, but is not of good quality. Black Morocco has produced fine bunches plentifully, but the berries have not set and swelled well, a common fault with this imposing Grape. These three varieties will be replaced by others. Madresfield Court is fine and the betries do not crack. Is not this evil the most prominent when the Vines are young and strong, and crops light? The crop is not light at Oakbrook. Lady Downe's is very good, and Black Hamburghs have yielded a great number of useful bunches. Late Grapes have their stalks placed in bottles of water, and are preserved in the fruit room; any that are wanted for use within three weeks have their stalks simply inserted in Potatoes and suspended in the room.

A large and excellent range of peacheries merits notice. Although the aspect is unfavourable no provision was made for heating the houses. For seven years no fruit was gathered; spiping was then placed in the houses, and every year since large and valuable crops of fine fruit have been produced. The trees are very fine and in superior condition. Atthough in full leaf they were pruned for the winter, or at least only a few of the tips will need to be cut from the shoots when they are tied to the treffix after the leaves have fallen. Mr. Hall observed that he could not see the use of leaving the trees crowded with wood and foliage after the crop was gathered; he therefore pruned them, and the result is that the wood for next year's crop is maturing thoroughly and perfecting bold buds. Advice of this nature has been frequently given in "Work for the Week," and those have followed it intelligently will find, or have found, the advantage of the practice.

Very little need be said respecting the outside department. The kitchen garden of three acres being some distance from the mansion was not visited; but on a very high south wall, the boundary of the home enclosure, some Pears were bearing good crops, but the fruit small and late. Amongst the pyramid and bush trees two Victoria Plums were bearing prodigious crops—ten times more in fact than any ten trees of other varieties were yielding. The fruit is preserved just as it changes colour. The Parsley-leaved Bramble is grown and valued for the heavy crops of fine fruit that it produces; it is both useful and ornamental.

Mr. Hall was a pupil of Mr. Frisby, a Lincolnshire gardener of high repute, and the practical knowledge he obtained at Blankney is being turned to profitable account at Oakbrook, for he is managing the gardens well.—J. W.

THE GLADIOLI JUDGING AT NEWCASTLE.—Allow me to enter my protest against the remarks wade by the Rev. C. P. Peach (page 248) regarding the Gladioli judging at Newcastle. I have seen many Gladioli in my time, and have both grown and exhibited them; but when I saw Mr. Spoor's stand, who so worthily took first prize, I considered it was the best stand I had ever previously seen. Regarding decoration, I consider no flower more needs it than the Gladiolus. I used to set mine

up with Asparagus and own foliage; but to set aside the flower for the sake of foliage, and especially foliage that was not Gladiolus foliage, would, I think, be a great mistake.—

J. WITTERSPOON.

THREE FINE SINGLE DAHLIAS.

It was in one respect fortunate that our Dahlias were mostly destroyed hast year, because I lost the few single varieties I had, and had to apply to a hady gardener, who makes herself happy growing plants not commonly grown, for a few plants to start with again. Amongst those sent were Dahlia coccinea, D. sarantiaca, and a single white form without name. These three are extremely beautiful, the white particularly so; in fact one of the finest white flowers I have ever seen. I hall be greatly obliged to have its name should any of your readers be acquainted with it. The flowers are doing good service just now in the way of furnishing large flower glasses, the foliage and bads of the Dahlias being freely used in arranging. Most flowers look best arranged amongst their own foliage, though there are some which will not do, and in other cases the foliage cannot be spared; but a wase farmished entirely with single Dahlias set in Dahlia leaves and buds is both attainable and beautiful.—R. P. PROTEERSETON.

PHOLIDOTA IMBRICATA.

This rare little Orchid is now bearing several of its peculiar and somewhat pretty spikes of flowers in one of the Orchid houses at Gunnerstury Park, the seat of Baron Rothschild. The plant is suspended in a small basket, and, like everything under Mr. Roberts's excellent management, it looks extremely well. The species is a native of various parts of India, in the same mountainous districts where P. pallida abounds—viz., Sylhet, Chittagong, &c., where it is found growing on the stems and branches of trees. The flowers are small, of a yellowish tinge, and are produced in dense, pendulous, alender flattened spikes, each flower being subtended by a small, brownish, scate bract, from which character the specific name is derived. The appearance of these spikes is suggestive of the Dendrochilums, but the flowers are devoid of the fragrance that distinguish those charming little plants.

There has been some confusion in reference to P. imbricata and P. pallida, for the latter was figured and described as the former in vol. xxi. of the "Botanical Register," but the mistake was subsequently convected, and the one originally described was named P. pallida from its flowers being white. There are also other differences between the species which are patent to the most cursory examination; for instance, the bracts in P. pallida are blunt, white they are acute in P. imbricata, and the spikes of the former are leose, whereas in the latter they are dense. The species under consideration has also the reputation of being more easily cultivated than the other. The Pholidotas are allied to the Ornithidisms, and included in the tribe Malaxidese. About ten species are known in this country, chiefly natives of the East Indies, and all have been introduced since 1820.—L. C.

FRUIT JUDGING AT NEWCASTLE.

In is the old story: exhibitors continue to see more charms in their own produce than they do in that of their brother competitors. Last autumn I endeavoured to get some of our horticultural authorities to arrange an exhibitor's guide, but failed. This season has again evidenced the necessity of a guide. Regarding the judging of the fruit at Newcastle, my impression at the time was that it was as near correct as possible, but that it was so close had either the equal seconds or the third been able to improve a single dish, then that stand would probably have taken first prize. Of the Newcastle Committee I think we may safely say that never did a more worthy body of gentlemen undertake the arrangement of an exhibition, nor succeed in establishing an exhibition more worthy of public patronage, and consequently in furthering the advancement of horticulture generally. It is my especial faith in these gentlemen's good intentions that prompts me this autumn to again return to fruit judging, as I think I can make a suggestion that they will appreciate and possibly adopt.

I considered that the schedule in the fruit department at the autumn show was too weak, but the Newcastle prize cards and the speedily printed return of the Judges' awards were as near perfect as possible. Now my suggestion is, and my hope is, as

the Committee go in for printing, that consequently they will adopt a further printed card to be placed by the exhibitor on his collections of fruit. To further aid explicitness the schedule should state the number of fruits that constitute a dish, and also give a list of the varieties of fruit an exhibitor can choose from. The proposed card for the exhibitors' and also judges' guidance must be printed in columns. The varieties of fruit admissible; next, a column stating the number of fruit to be placed on each dish; a third column stating the number of points each dish is to count if the said dish be perfect; next, to the right of the card, there must be a blank column on which the judge or judges will mark the number of points they consider each dish worthy of. The adding-up of these points will tell the tale; and when the exhibitor comes to see his award he will see the exact value the judges have placed upon each of his exhibits, and he will also see the value of each dish in the different collections.

This arrangement I do think, whilst it would tend to diminish regretable grumbling, would also tend to general enlightenment as to the good properties of fruit; and I do not think that gentlemen, even so worthy and so high in their profession as the Messrs. Coleman and Johnston, who were the Judges at Newcastle, would thereby lose a particle of dignity.

The following is the form of card I propose, and to illustrate exactly my meaning I have filled up the judges' column according to my opinion of the collection of fruit exhibited by Mr. Laidlaw.

Each dish to contain s	Fruit dmissible.	Points	Judges'
1	Pine		8
2	Bunches of Black Grapes	8	8
9	White ditto		8
6	Peaches	6	4
6	Nectarines		4
1	Melon		8
6	Figs		6
6	Apricots	4	ŏ
6	Plums		
6	Pears.		=
6	Apples		
1	Pint Strawberries		
1	Pint Cherries		

Mr. Laidlaw first with Points 45 Judged by this rule I found Mr. Westcott's total 44 points. Of course when the cards are printed the last column must be left blank to be filled in by the judges.—J. WITHERSPOON.

WORK FOR THE WEEK.

FRUIT HOUSES.

Vines.—With so many good varieties of late Grapes that we now possess early forcing is not by any means essential for a supply of Grapes all the year round. The most valuable of late varieties is Lady Downe's; it bears well, and the fruit keeps quite plump and fresh up to May. In quality it is unsurpassed, for when ripened in strong heat the Muscat flavour is more highly developed than in a low temperature. This, as well as all late Grapes, owes much of its late-keeping properties to thorough ripening under the influence of sun and strong heat; in fact, Grapes that are to hang for any length of time must not be ripened in cool vineries. Black Hamburgh, for instance, will not remain in good condition nearly so well if ripened in a cool house as when the fruit is perfected by fire heat, whilst Muscat of Alexandria speedily becomes spotted when not ripened to an amber andria speedily becomes spotted when not ripened to an amber andria speedily becomes spotted when not ripened to an amoer colour. Black Alicante is an excellent keeper, and always finishes well. West's St. Peter's also finishes well in a high temperature, and though not so imposing in bunch and berry as some others it is one of the best late Grapes. Gros Colman is simply magnificent in appearance, the berries 4 or more inches in circumference, the bunches about 4 lbs. in weight, and when well ripened it is not nearly so coarse and inferior in flavour as it is sometimes represented to be 1 trequires however a longer time to colour and nearly so coarse and interior in havour as it is sometimes represented to be. It requires, however, a longer time to colour and ripen than the majority of late Grapes. Gros Guillaume is really imposing in appearance, the bunches being large and the berries approaching Gros Colman in size; and when well ripened and coloured the quality is good. Trebbiano and Calabrian Raisin with Syrian are good white companions for the preceding, being large in bunch and berry, and when well ripened excellent in quality and good keepers. With these varieties to maintain the supply up to May the necessity of starting permanently planted quality and good keepers. With these varieties to maintain the supply up to May the necessity of starting permanently planted Vines before December does not arise, unless it is desired to have fresh ripe Grapes at an early date in spring. In that case it is preferable to take the early supply from Vines in pots than to start the permanently planted Vines so early. Vines in pots produce fruit but little inferior to that borne by those planted out, and often better, from the roots being inside; and where there is convenience of affording bottom heat success is certain, providing, of course, the canes are sufficiently strong and well ripened. Where

leaves and stable litter have been prepared as advised in our last calendar they should be placed on outside borders about a fortnight before closing the house, and a quantity of the material introduced at that time to the interior of the house will produce introduced at that time to the interior of the house will produce a regular degree of heat and moisture without having to resort so much to fire heat and frequent sprinklings. Vines in pots plunged in bottom heat must not have a greater heat than 65° to begin with, augmenting it by bringing up the fermenting materials to the level of the pots, so as to raise it to 70° or 75° when the Vines are in leaf. Both Vines in pots and early forced Vines have vines and off so lets that event under pressing circumstances is ripened off so late that, except under pressing circumstances, it will be sound practice to defer starting to as late a period as possible. Young Vines that have completed their growth should have a portion of the laterals cut off to admit light and air to the principal leaves and buds, thereby inducing earlier ripening of principal leaves and buds, thereby inducing earlier ripening of both wood and roots. Vines in pots not intended for early forcing should be placed under cover, an open shed with a north aspect being suitable, and the pots covered with dry straw or ferm. Keep a sharp look-out for decayed berries among ripe fruit; a slight warmth in the pipes when the atmosphere outside is charged with moisture is advisable.

FLOWER GARDEN.

This is now as gay as at any time during the season, for though a few degrees of frost have affected some of the most tender plants, there has not been sufficient to kill Coleuses and Alternantheras. All Pelargoniums when housed should have a dry atmosphere, but when they are fairly established moisture must be given at the root and sufficient heat (50°) to maintain steady progressive growth. Alternantheras, Coleuses, and Iresines should have a minimum temperature of 60° to winter them successfully. Verminimum temperature of 60° to winter them successfully. Verbenas, Ageratums, Petunias, &c., do well in any light airy position, frost being excluded. Succulents of the half-hardy types, as Echeverias, Sempervivums, Pachyphytums, Kleinias, Aloes, Agaves, Mesembryanthemums, Sedums, &c., should at once be taken up and potted in good open soil, and placed in a dry warm house or pit until established, when they may be removed to a cooler situation with advantage. In the case of spring gardening no time should be lost in placing out the plants, in order that they may have time to become established before winter. Nothing is so cheerless as hare beds in anring and with the expenditure of a may have time to become established before winter. Nothing is so cheerless as bare beds in spring, and with the expenditure of a few pounds in bulbs, such as Hyacinths, Narcissuses, Tulps, Crocuses, Anemones, &c., supplemented with Snowdrops, Scillas, Prinroses, Polyanthuses, Daisies, Violas, Pansies, Aubrictias, Arabises, and other plants, aided by Wallflowers, Nemophilas, and Silenes, will go far to make a garden gay and inviting in spring. Before digging the beds preparatory to planting, a good dressing of manure should be given. Tuberous-rooted Begonias need not be removed until they are affected by frost, and then should be lifted removed until they are affected by frost, and then should be lifted like Dahlias, laid in a shed for a few days to part with superfluous moisture, and afterwards stored away in sand in a place safe from moisture, and afterwards stored away in sand in a place safe from frost until spring. Choice Hollyhocks are not safe in severe winters without protection, and to make sure it is better to winter them in pots in frames, when they can easily be increased by division and cuttings. Now that the lawn mower is not in such frequent requisition noxious weeds, as Daisies, Plantain, &c., disfigure the lawn: these should be extirpated. The recent rains have brought worms to the surface and disfigured it by the soil they cast up. Water the lawn with lime water, which soon brings them out, when they may be swept up and cleared away. This will save much time in sweeping and rolling. Rich velvety laws will save much time in sweeping and rolling. Rich velvety laws will save much time in sweeping and rolling. Rich velvety lawns are the pride of English gardens; they should be kept in the best possible condition by sweeping and rolling frequently; indeed sweeping and cleaning up of lawns and walks will be the order of the day for a long time to come, as leaves and worms cause no end of labour. The planting of evergreen trees and shrubs should be proceeded with, commencing with the deciduous species as soon as the majority of the leaves have fallen. All alterations as opportunity offers may be done, such as taking up, levelling, and relaying turf, making fresh walks, and lifting and replanting Box or other edgings; such work done now will be so much time saved in spring.

TO CORRESPONDENTS.

BOOKS (M.J.).—The "Ratable Funguess of Great Britain" published at this office, price 7s, 8d., post free 7s. 8d., will suit you. We cannot from your description of it name the fungus in your Mushroom house.

ADDRESS (A Subscriber).—As your substroom nouse.

ADDRESS (A Subscriber).—As your letter has failed try one to the old address—Mason View, Didsbury, Manchester. If this fails also we can perhaps give you some information that may be useful if you will state your requirements. (A Subscriber).—Rev.C. P. Peach, Appleton-le-Street, Malton, Yorkshire. (A New Subscriber).—If you state your requirements to Mr. Smith, Curator, Royal Gardens, Kew, you will probably obtain the information you desire. tion you desire.

WHITE CLEMATIS (J. P.).—The variety is, we think, either Henryi or Gloire de St. Julienne, but we cannot be certain from only seeing a crushed and faded flower. Mears. Jackman & Son, Woking, are great growers of Clematises, and all the best varieties may be seen in their nurseries.

HOYA CABNOSA (W. H. C.).—The Hoya will grow perfectly well in a conservatory in which the temperature during winter "never falls below 46°." We have seen the plant referred to by Mr. Luckhurst, which is growing freely and flowering profusely on the back well of a vinery, and the tempera-

ture of the house is probably frequently below 45°. Few plants succeed better in the shade than this does, and it is a little surprising that it is not more frequently seen on the back walls of vineries and conservatories.

more frequently seen on the back walls of vineries and conservatories.

LA FRANCE ROSE FOR WINTER (Idem).—Although this variety is a continuous bloomer and forces very well, you will yet experience some difficulty in producing blooms of it at Christmas. The only mode of doing so is to have healthy plants with well-matured wood, which should be pruned now, but not too closely, placing the plants in a very light and moderately head house early in November, increasing the temperature as required according to the condition of the growth and advancing buds, if any. Tes Roses may be had in flower at Christmas by this practice, and possibly you may succeed in flowering La France at the same time, but much will depend on the weather. We have not grown this variety for winter flowering, but depend on Tea Roses for that purpose. on Tea Roses for that purpose.

FILBERTS NOT MATURING (Ashdown).—The failure of your Filberts to develope kernels tends to show that your soil is deficient in phosphates and alkalies. A dressing of quickline and wood ashes will correct this if applied at the rate of a bushel of lime and two of ashes to a square parch.

GROWING FRUIT FOR MARKET (M. D.).—So much depends on local demands that we are not in a position to answer your questions satisfactorily. We should hesitate to destroy all the Black Hamburgh Vines, as the fruit can be ripened with little expenditure of fuel. Cucumbers when well grown and placed in the market early are profitable, and they travel well to any distance. Tomatoes, too, for which there is an increasing demand, are grown with advantage under glass in many places, strong plants of Tomatoes being ready for occupying the house immediately the crop of early Cucumbers is disnosed of.

LEAN-TO HOUSE FOR ROSES (A Lover of Rose Shows).—Hight feet is much too high for the front of so narrow a house, rather let it be 5 feet—3 of brickwork and 2 of glass. The cheapest way of procuring materials for building such a house is to send the size and length of the sashbars to any of the steam saw mills, and they will supply them with the rabbets made ahready for the glass, together with the requisite deal scantling for ventilators and doors. Glass can be had from a glass merchant, and is now very cheap; that which you require is 21 ox. seconds, and costs about 18t. per 100 square feet. No front ventilation will be required provided you have ventilators all along the top, and an opening of quite 2 feet wide. Your idea of climbing Roses on the back wall is a good one. Make a low flat stage along the front solely for pot Roses; the height of the stage from the floor will depend upon the size of your plants. A brick flue will answer perfectly well for heating, dry heat being given off by every kind of apparatus. The porous nature of bricks instead of being a source of evil is an advantage, for they absorb moisture when cool and give it off in the form of vapour when heated. This reply is given on the assumption that you cannot employ a horticultural builder; but those experienced in the trade are, of course, more competent to erect better structures than you can in the manner suggested.

FERTILISERS FOR GARDEN (J. W.).—You will find the best Peruvian

FERTILISERS FOR GARDEN (J. W.) .- You will find the best Peruvian FRITLIBERS FOR GARDEN (J. W.).—You will find the best Feruyan guano applied during showery weather as a top-dressing when the crops are in a growing state an excellent fertiliser. It may be applied at the rate of about 2 coz, per square yard. Superphosphate of lime is also good and may be applied more freely; and you will find nitrate of soda particularly stimulating to such green crops as Canliflowers, Lettuces, Cabbages, &c., if applied at the rate of an ounce to the square yard. The three fertilisers named, if properly applied, will aid you in producing good crops of vegetables.

GRAPES NOT COLOURING (A. P. B.).—Your Grapes will not colour now. Overcropping is the most common cause of deficient colour, and although you say your crop is "good but not heavy," it may yet be too heavy for the Vines to perfect. Assuming, however, that the fault is in the soil we should remove a portion from the surface, just baring the roots, and give a heavy dressing of wood ashes and fresh turfy loam, surfacing with manure. The sooner this is done the better, and the additional surface roots that will or ought to be promoted cannot fall to benefit the Vines. You cannot use wood ashes too freely in the surface dressing.

GRUBS ON PEAR TREES (G, F, M).—Your Pear trees are attacked by the slimy grub of Selandria æthiops, which is very destructive when permitted to become established. It may be eradicated by frequent dustings of freshly alaked lime

MAKING CUTTINGS (Amateur).—It is impossible to state how many leaves should be removed from the cuttings, and we can only say generally that, unless in particular circumstances, as many leaves should be removed as would enable the cutting to be firmly fixed in the cutting pot, and if the leaves be large a portion more may be removed or lessened in their dimensions in order to reduce the evaporating surface, success consisting in keeping the cutting healthy and yet preventing it from parting with its stored-up juloes; and hence the reason why we cover them with bellglasses, and shade them from bright sunshine. The more leaves left, provided they can be kept healthy and vigorous, the sooner will roots be formed by the elaboration of fresh material, and the more quickly and without flagging will this elaboration take place the more light the leaves receive. Shading, or diffused light, is essential at first, but the sooner it can be dispensed with the better. Continued too long the shading would make the cuttings weak and spindly.

PENTAS (Parker).—We are not acquainted with a pure white species or variety, but the flowers of P. carnea occasionally change to a blush white. If a pure white variety is in commerce we will readily record the fact on receiving information from any of our readers to that effect.

CATERPILLAR (L,J,K).—It is a nearly full-grown caterpillar of the Swallowtail moth (Ourapteryx Sambucaria). The imago, or perfect insect, fits about gardens in June, looking ghostly in the twilight. It is the habit of the caterpillar to hybernate, and as the weather grows colder the specime noticed will probably resort to some sheltered spot, feeding again a short time in the spring. The curious attitude you describe is assumed as a disguise, preventing the caterpillar from being attacked by birds. There are three pairs of feet (retractile) attached to the three segments of the body following the head three pairs of feet following the head.

HEBBACEOUS PLANTS (A Six-years Subacriber).— Achillea aures, A. Ptarmica plena, Aconitum pyrenaicum, Adonis vernalis, Agrostemma coronaria fiore-pleno, Ajuga genevensis, Alchemilla alpina, Allium ciliatum, A. grandifiorum. A. neapolitanum, A. fragrans, A. triquetum, Alyssum orientale, Anemone apennina, A. hortensis, A fulgens, A. japonica alba, A. narciscifiora, A. ranunculoidee, Anthericum Liliastrum, A. Liliago, Anthyllis montana, Aquilegia chrysantha, A. vulgaris alba, Arabis albida, A. bispharophylla, Armeria cephalotes, Aronicum glaciale, Asphodelus luteus, Aster coccineus,

A. Amelius majus, A. rigidus, A. grandiflorus, A. tenuifolius, A. longifolius formosus, Astragalus vaginatus, Aubrietia deltoidea aurea, A. deltoidea grandiflora, Betonica grandiflora, Borago laxifolia, Botzyanthus paradoxus, Bulbocodium vernum, Calochortus luteus oculatus, C. venustus, C. elegans, Caltha palustris flore-pleno, Campanula aggregata, C. Hendersoni, C. iso-phylla and var. alba, C. alba macrantha, C. ranunculoides, Cardamine pratensis flore-pleno, Chelidonium grandiflorum, Colchicum autumnale flore-pleno and var. album flore-pleno, Convaliaria majalis and vars. rosea, plena, C. Polygonatum, Coreopsis auriculata, Corydalis lutea, C. cava abifora, C. eximes, Crocus speciosus, C. Sieberi, C. sativus, Cyclamen hedereefolium and var. album, Cynoglossum apenninum, Delphinium alopecuroides, D. Barlowi, D. belladonna, D. magnificum, Dianthus floribundus, D. gracife, D. fragrans, D. neglectus, Dictamnus Fraxinella and var. albus, Dielytra spectabilis, Doronicum Clusi, Dodecatheon integrifolium, D. Meadia and var. album, Epilobium latifolium, Epimedium pinnatum elegans, Erythronium americanum, E. Denscanis and vars. album and roseam, E. giganteum grandiflorum, Francoa appendiculata, Fritillaria meleagris and vars. alba and plena, F. nudica, Fuchsia corallina, F. Riccartoni, Funkia undulata fol. aurea var., F. undulata fol. aurea var., F. undulata fol. aurea var., F. undulata fol. aurea var., J. reduculata plena, Hyacinthus candicans, H. amethystinus, Hypericum calycinum, Iberis corifolia, Inula glandulose, Iris acuta, I. germanica vars., I. reticulata vars., Jasonia glutinosa, Lathyrus grandiflorus, Leucojum vernum, Lilium auratum, L. candidum, L. chalcedonicum, L. superbum, L. tigriaum spiendens, Lobelia fulgens, L. syphilitica, Lupinus nutxansis, Lychnis Flos-Jovis, L. diurna flore-pleno, Meconopsis cambrica, Mimulus vars., Myosotis disatifiora, Narcissus Ajax, N. poeticus plenus, N. incomparabilis, Nepeta Mussini, Gnothera fruticosa, G. macrocarpa, Orobus vernus, Peonica, Pulmonaria azurea, Ranucculus amp

HOUSE FOR STRAWBEREIES (A Subscriber).—If the house is staged entirely for Strawberries, and it is, as it ought to be, a light house, the stage may be 3 feet from the glass; the plants then receive all the light they require, and room is afforded for watering them and gathering the fruit. In Lord Londesborough's garden at Norbiton the Strawberry stages are more than 3 feet from the glass, and in few places are better crops produced. When shelves are suspended they may be from 18 inches to 3 feet from the glass, as is convenient. The time for placing the plants in the house depends entirely on the time at which ripe fruit is required. From January to March is the usual time for securing a succession of good crops.

January to March is the usual time for securing a succession of good crops. GRAPES WITHERING (A Constant Reader).—It is impossible for anyone to state the cause of your Grapes withering without knowing in what condition they are. They may have simply shrivelled, or they may have shanked, so without seeing berries we cannot answer your question. Primulas damp off when placed in a cold damp house, and when they are watered injudiciously. If the plants are placed on a shelf in a well-ventilated house, having a night temperature of about 45°, and are watered carefully, not wetting the stems or foliage, the damping will be arrested. The name of the plant, a leaf and flowers of which you have sent, is Hoya carnosa.

The PROCEST LYMPALETY (A Press)**—Harding recently been excessed.

VINE ROOTS UNHEALTHY (G. Poses).—Having recently been engaged in a close examination and investigation of the phylloxera in the south of Burope we are perfectly acquainted with its symptoms, and are able to assure you that the roots sent contain no trace of the pest. The roots are injured by canker, caused either by want of drainage or unsuitable soil. So far as we can judge by the soil particles adhering to the roots we suspect that vegetable matter unduly preponderates in the compost, and that the border is deficient in mineral matter.

LIQUID MANURE FOR GREENHOUSE PLANTS (H. T.).—Perfectly clear soot water would be an excellent stimulant for the plants you name, and is not offensive. If you suspend in a rough beg about half a peck of soot in about 20 gallons of water for a few days, and then place in the water a few lumps of lime, you will shortly have soot water as clear as sherry. At this strength the soot water may be applied diluted with half its volume of pure water. A pinch of superphosphate of lime sprinkled on the surface of the pots once or twice a week and watered in would also be a suitable application. Prentice Brothers' fertiliser—"For Vita"—sold by florists, is not only not offensive but is slightly perfumed, and might answer your purpose.

PIPING REQUIRED FOR HEATING GREENHOUSES (Attention Reader).—To secure a temperature of 80° in all weathers the extent of 4-inch piping per 1000 cubic feet of air will require to be 80 feet, but much depends upon the extent of the glass surface. A good formula for finding the length of 4-inch piping to heat a structure to any given temperature is to "multiply the glass or exposed superficies in feet by eleven times the intended difference between the outside (33°) and inside (in your case 50°) temperatures, and divide the product by fifteen times the intended difference between the heat of the water (180°) and the air of the house." PIPING REQUIRED FOR HEATING GREENHOUSES (Attentive Reader).

PLANT (*Idem*).—According to your description it is Viburnum Opulus, the wild Guelder Rose, the berries of which are not poisonous. It is propagated by seeds, which take two years to germinate, by layers, and by cuttings of the ripe wood in autumn inserted in sandy soil in a shady border.

NAMES OF FRUITS (Connaught Subscriber).—The single Apple is Dutch Codlin. We are sorry we cannot name the others. (C. E. Fenton.)—The Apple is London Pippin; the Plum is Coe's Golden Drop. Your seedling Apple not being ripe we cannot form an opinion upon it. (——).—2, Ord's Apple; 8, Dumelow's Seedling; 5, Ribston Pippin; 6, London Pippin; 7, Court of Wick; 8, Royal Russet. Large Pear Van Mons Leon Leclerc,

brown Pear Bearre de Caplaumont. (C. II.).—Pear, Vioar of Winkfield;
Apple, Aromatic Russet. (Elm).—The Flum is Washington.

NAMES OF PLANTS (J. Lensdell).—Ampelopsis japonica. (J. Wilson).—
The flower is Valeriana officinalis alba, and the plant may be increased either by cuttings or division of the roots, the latter being preferable. (H. W.).—1, Anemone japonica; 2, Sidalcea oregana; 3, Lysimachia vulgaris; 4, Centaurea montana. (Winchester).—Cerinthe major, the Great Honeywort. (Elm).—1, Begonia insignis; 2, Resembles B. Ingramii; 3. B. Dregei.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

BREAKING-UP INFERIOR GRASS LANDS.

THE breaking-up and improvement of pasture land is probably of greater importance to the home farmer in the management of park and gress lands than to the occupiers of farms in general, because of the park and ornamental pastures belonging to the setates of noblemen and gentlemen, in which cases the question of uniformity in appearance of the turf is of the greatest consequence, and where possible it should always be regarded as one of the first objects to be obtained and maintained in home farm and gross land management. It must, however, be understood that an even turf cannot easily be obtained where the mixed soils prevail, for we often find in one range of pastures not only a variety of surface soils, but of subsoils likewise. Now, these variations must naturally influence the growth of the grass not only as to quantity of produce, but also in the quality of the herbage. It is frequently found in various districts in parks and pastures that the land is composed of sand, clay, gravel, or peat and their combinations; it is therefore almost impossible that these variations of soil should afford an even turf under the most intelligent management and liberal outlay for manures &c., without breaking up. Upon some soils the coarse hassock grasses, rushes, and other weed-like herbage is indigenous to them, and, however we may attempt to rid the pastures of these objectionable and unsightly weeds, it is often out of question to raise such pastures or parts of pastures into a state to harmonise with the portions which may be naturally good and producing grasses of the best kinds. We have often seen it attempted, by manuring and otherwise, to improve some of these worthless pastures; indeed, we have in several cases done this upon our farm without the desired effect, especially in cases when the land required draining, chalking, marling, &c. For although we have given full directions for the improvement of pasture and park lands without breaking up-both as to manuring and compost dressing by the application of earthy matters, &c.—in this Journal (in articles dated January the 24th, 31st, 1878, at pages 75 and 95), yet the treatment there recommended will not be entirely successful under certain circumstances and certain conditions of soil. It will on this occasion be our endeavour to explain these by alluding to such plans and methods of proceeding as have proved succossful as experiments carried out by intelligent men, and also by ourselves. In order to direct the attention of the home farmer to these matters in detail we shall give various illustrations, not only of success, but of failures also, so that by contrast we may arrive at conclusions which may be safely relied on.

Our first illustration refers to a meadow which, although we had successfuly drained it 3 and 4 feet deep, yet as the soil was in some parts a strong stony clay and the herbage very coarse, including also various pernicious weeds, and the pasture having shown but very little improvement after liberal manuring, chalking, &c., we determined upon breaking it up, and on account of its situation converting it into arable land for future cultivation and the growth of various farm crops. In doing this we committed our first mistake in breaking up pastures, and as it proved a caution to us ever afterwards we must ask our readers to consider carefully the details of the question. This comparatively worthless pasture, or meadow as it may be termed, for the most part consisted of clay, but there were portions of peat, gravel, and sand, so that it may with truth be called a patchy or mixed soil. This was one of the chief reasons why it did not yield to

treatment of a general character, as the margins of the different soils were not sufficiently defined for separate treatment whilst the land was in turf. To commence cultivation we ploughed the land very deeply in the month of December, probably from 7 to 8 inches, involving heavy labour for four horses attached to the plough. The sward being extremely tough the furrows did not turn over readily or so uniformly as we could wish; we therefore employed a man to follow the plough and adjust the furrows where they did not lie properly, in order that when the land was worked down the harrows, roller, &c., may have full effect. The land having laid exposed to the alternations of winter weather was in good condition for tillage in the spring, and by giving it a considerable number of draggings, harrowings, &c., the surface became fine with pienty of loose mould to receive the seed. The crop we intended to grow was Black Tartarian cats; these were drilled about the litth of March with 4 bealeds of seed per acre, which must be considered an ample quantity for ensuring a full plant as far as seed is concerned, particularly as the land was in good order and the seed well buried. We calculated that the old turf from being ploughed under a deep furrow early in the winter would by the seed time, or at least during the growth of the cats, become sufficiently decayed to furnish an abundant supply of humus manure and other plant food to produce a fine crop both of straw and grain, and so it would have done had we not committed this our first missake, by ignoring the power of the enemies to the crop, which we certainly ought to have estimated and not defied them. The consequence was that soon after the cats came up, which they did with great regularity, numerous enemies attacked the young oat plants, such as wireworms, graba, slugs, &c., and the plant at harvest was not half thick enough, for although the straw was very strong and coarse yet the yield of grain proved to be only about three-quarters per acre—that is, less than ha

crop should be potatoes.

This was our first mistake, which induced us to adopt a different plan; and our second illustration of breaking up pasture we carried out in the adjoining meadow which had been properly a properly drained. It consisted of mixed or rather different soils in patch similar to the field we have just described, and in order to avoid mistakes such as we had previously committed we had the land "burn-baked" as it is locally termed—that is, pared and the turn turned. This was done by a set of men who undertake to breast plough and out up the turf, and burn it, for so much per scre; and these men are certainly from great and continual practice in the work very clever, and burn the turf with great judgment, the process being called eddle burning, the object of which is to produce black ashes, approaching in substance and value to that of charcoal. Instead of burning the turf into red or white ashes by excessive heat and the turf laid on perfectly dry, it is laid on excessive heat and the turf laid on perfectly dry, it is laid on somewhat damp, in order that it may not burn too quickly, but become charred rather than burned, and in doing this great care and attention is required to prevent any part of the heap from burning through to the outside for any red or white ashes to be visible. The turf having been burned in this way gave an inamense quantity of valuable ashes, and enabled us to plough and press the land after spreading about two-thirds of the ashes, one-third being removed and used as manure for root crops. This proved sufficient to produce a fine crop of care succeeded This proved sufficient to produce a fine crep of cats, succeeded by other crops equally good in connecements of the committee by other crops equally good, in consequence of the enemies to vegetation having been destroyed by the action of fire in charring the turf. The advantage obtained in this instance was the mixing of soils in the act of tillage, also bringing into opera-tion the chalk which had been previously applied whilst the land was in pasture, and which had sunk into the soil and become inoperative after a certain time. This field is to this day capital arable land, and has borne a succession of valuable crops both of corn and roots, and for a number of years required but very little assistance by manure, it being maiden earth; and in pursuing the subject we shall give further illustrations important to the home farmer.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—The time for sowing wheat has now arrived and on the hill districts of the western and northern counties has been going on for some time; yet, on account of the lateness of

the harvest, much of the horse labour will be still employed in sowing seeds of the fodder crops, such as vetches, rye, trifolium, &c., to the delay of wheat sowing. We notice that very little autumn tillage has been done this year, even in those early districts and dry soils where the harvest has been finished at the earliest period. Digging potatoes, also, ought at this time to be well forward; but the land in general is more covered with weeds than after a dry kind summer, the horse labour will therefore be heavier, and the working of the potato-lifting plough not so easy as in ordinary seasons. The land will also require much more as in ordinary seasons. The land will also require much more harrowing, &c., to separate the crop from the weeds and clods, and the odd horse or horses will have a proportionate heavy work in carting away the accumulations of rubbish after the potato tubers have been taken to the store or placed in pits. We must observe also that there will be less fear of the potato tubers decaying in the heap or store when they have remained in the land until this late region because the diseased tubers will have seen as the diseased tuber will be a proved because the diseased tubers. land until this late period, because the diseased tubers will have decayed and become mixed with the soil, after which we have found they prove good manure for fature crops, especially for cereals. We must call attention now to the sowing of wheat, for we find that the new grain will not vegetate in some instances, we find that the new grain will not vegetate in some instances, and is in many instances so thin and light that many of the samples will be found unfit for furnishing a strong healthy plant. However good condition the land may be in at seed time, yet the plants whilst young have to depend upon the mother corn, and when the grain is not matured the infant plants will be weak and the more easily become a prey for the wireworm, slags, &c., and also less able to withstand the effect of the early frost or heavy rains of winter. When the land is ploughed and pressed out of clover leafor wheat we prefer sowing after the presser, as the seed is haried for wheat we prefer sowing after the presser, as the seed is baried a good depth in the land and not so likely to be lifted out by frost. There was a special instance of this last winter, for where the wheat was sown after the presser broadcast it proved in every instance a more regular plant in the spring than drilled wheat, because the lea ground is sure to shrink more or less by the action of frost unless it has been very early ploughed, say in July or August, thus giving time for the land to settle down firm. As the new wheat this year of our own growth is not so well fitted for seed, in some cases not more than 50 per cent. vegetating, we recommend that some samples of old wheat should be sown instead, or otherwise some of the prime samples which we see imported from America may be grown with a surety of a good plant, because, being so well grown and also well harvested, the corn is sure to vegetate with regularity. At the same time we think that the change of soil and climate will favour the growth in England, particularly if care is used to select the best samples of both red and white varieties, the red varieties for strong land and white for dry friable soils.

Hand Labour.—The men, women, and boys should now be employed in picking up and sorting the potato tubers as fast as they are raised by the potato plough, and this work will now be diminished and simplified in consequence of the diseased tubers having decayed; the storing and pitting may therefore proceed without hindrance. The crop of mangolds should now be lifted, and as fast as they are taken up and the tops twisted off by hand—we do not like cutting them off—they should be carted to heap or storehouse the same day, because if left out at night even in slight, frosts they are sure to receive more or less intime. slight frosts they are sure to receive more or less injury. The leaves should be ploughed in as soon as there is room for the ploughs to work, and when covered up in the soil in the green state they prove a capital manure for cereal crops. Analysis shows that they contain a large amount of potash, and we prefer shows that they contain a large amount or potasn, and we prerer ploughing-in to feeding-off by sheep, as they are not very healthy food for sheep, even if they have a change of other food with hay in addition. The leaves, too, will be of use by spreading some over any crops, such as trifolium, rye, winter vetches, or young wheat which may be suffering injury by the depredation of slugs, for the slugs are sure to take shelter under the leaves, when they may be picked off and carried away daily. In stocking with cattle do not buy poor animals, but take those which may be just beneath the butchers' quality, and put them into the boxes for fattening, giving them not more than 60 lbs. of roots, 4 lbs. of cake, and 2 lbs. of meal daily, with sweet straw ad libitum or cut into chaff; but of meal daily, with sweet straw as solutions of cut into chair; but where straw is plentiful we prefer giving it long in racks, and the portion not eaten serves to litter the boxes or pens. Sheep now on turnips will require either a full allowance of the best hay or else a liberal allowance of bean or barley meal. No doubt, as the hay has been badly made this year, the damaged grain both of barley or wheat will answer better as food for the stock that to be sold at a low price. In stocking-in with sheep, as root food in many instances is short, it may be best to buy lambs to come out for sale as tegs by shearing time instead of ewes to produce lambs, as they require so much food in the spring.

THE POULTRY CLUB.

A COMMITTEE meeting of the Poultry Club was held at the Agricultural Hall during the Dairy Show. Present—The Hon. and Rev. F. G. Dutton (President), T. C. Burnell, A. Darby, S. Matthews, Rev. J. D. Peake, Rev. H. R. Peel, and O. E. Cresswell

(Hon. Sec.) There were elected members—Mr. R. R. Fo Aylesbury, and Mr. H. Jenkins, Mountain Ash, South Wales. -Mr. B. R. Fowler,

A complaint of Mr. P. Ogilvie was considered, that he had never been able to obtain a medal which he won at the Dairy Show in 1877. The Secretary was instructed to write to the person

believed to be responsible for its payment.

The following letter addressed to the Secretary of the late Winchester Show, and forwarded by him, was read to the Meeting:— "St. Day, Cornwall.

"SIR,—I don't mind entering a Game Bantam pullet and sub-scribing £1 ls. towards the Show if you can guarantee me the first prize in that class. I think she would stand a good chance for the first. Of course it would not be known by me that I subscribed in that way and taking the first. If you will agree to my offer please answer as soon as you can, and I will send on the form of entry. And you deduct the guinea entrance fee and 7d. for the catalogue, and you send the rest to me after the close of the Show, which will partly pay for the carriage, and hoping that I shall make a large number of entries at your next Show.

"I am, yours truly,
"F. M. CORFIELD."

A complaint made about a Cochin shown trimmed at the Glossop Dale Show was laid before the Committee, and it was decided that

the matter should be inquired into.

The question of Mr. Chatworthy's Cochin hen disqualified at the Ross Show was considered, and the Secretary was requested to make further inquiries about the matter.

The Secretary was also requested to write to Messrs. Chadwick, wing for which they were disqualified at Hemel Hempstead.

The next Committee meeting many and the state of their desired the state of the state of their desired the state of the and ask if they have any explanation of the state of their drake's

e next Committee meeting was fixed for Thursday, 23rd inst., at Oxford.

NOTES ON POULTRY AT THE DAIRY SHOW.

THROUGH last week the gallery of the Agricultural Hall was filled with the exhibition of poultry and Pigeons in connection with the Dairy Show. The light was good, and certainly the place is an admirable one for the purpose. The poultry on the whole was by no means what it has been in other years; still, considering the extraordinary season we have just passed through, there were few years remarkable highs though havened them in most classes. a few very remarkable birds, though beyond them in most classes came a poor lot. Criticism on birds shown has of late been carried to an absurd point of minuteness. We do not therefore purpose to give descriptions of every prize bird, which probably has been described before, and before the season is over will often be described again, but simply to reproduce the notes which we made on the best birds in the classes.

Dorkings.—The first and second coloured cockerels were very remarkable. We took much time to make up our minds which we liked best, and hardly came to a conclusion in the end. First was remarkable. We took much time to make up our minds which we liked best, and hardly came to a conclusion in the end. First was good in colour and feet, an enormous bird, which will look even larger when his neck hackle has fully grown, and with a perfect comb; second, deep-breasted and a noble Dorking, the Hemel Hempetead cup bird; his only fault is a slight curve in toes, from the early cold doubtless. The first-prize bird found a purchaser at £42. The first-prize dark pullet will make a fine hen. We are glad to see prizes given to birds of her more moderately dark colour; the very dark brown hens, in favour of late, produce cockerels too black; second a nice short-legged bird. The class for pairs of any other variety had nineteen entries, but few pens were worth looking at. The first Silver-Greys were by far the best, though we failed to see a good Silver-Grey pullet in the class. The second Whites were fair. Cockins were an extremely poor lot; few of them merit notice. Some Partridge entered in the Buff class received prizes, a most unfair thing in our opinion. The birds were muddled up together in an extraordinary fashion. The cup went to a presty pair of lemony Buffs; the cockerel's wings not good in colour. Some of the other winning Buffs we thought simply frightful. The Partridge in their proper class were all ragged and poor. Whites too were very shady. Brahmas.—The first-prize Dark cockerel and the first-prize pullet were both magnificent, quite Mr. Lingwood's old type of birds. were both magnificent, quite Mr. Lingwood's old type of birds.
The second award in Dark pullets was a mystery to everyone—
a poor, small wry-back bird! The cup Light cockers! was a shortlegged bird, good in shape, too much hocked. The four prize pullets were all close together and all very fair birds. Spanish were not remarkable: eleven pairs only were entered; the cockers in the cup pen struck us as the best bird. Houdans were moderate. Sixth claws seem now in vogue; we always thought the fifth de trop, but if six are to be required we can only say to fanciers, Avoid Houdans! Crèves were not generally in good condition. Avoid Moudans I Crees were not generally in good controlled. The first-prize birds were certainly ahead in size, but in the general qualifications of a prize pen we preferred the second. Hamburghs made three small classes. We liked the first Golden-spangled, their moons might be more evenly distributed. The Fencilled were not good. First Golden, the best in the class, but not an Al pair. Blacks were much better; the cup pen specially good, and many others beautiful in gloss. Game were only fair all round. We dislike the ever-increasing size of winning birds, evidently due

managed, and the fine weather enabled visitors to see the birds wall late into the afternoon, and the obnoxious gas was not as on some former consistons flaring in their faces.

Domain Note folimered for weather the problem of the

to Malay blood. The pullets were in better condition than the cockersia. Melays were pretty good in both classes—viz., for cockers and feeling were pretty good easily absent. Follows the winning bird stood easily absent. Follows the winning bird stood easily absent. Follows the winning bird stood easily absent. Follows the cockers and second pen, both filters and second pen, both filters, particularly good. Andalusians and Mesonecus.—A large class and good. First and third were nice Black Minorcas, and second good Andalusians; the cockers particularly fine. Legherus.—The winners of first honours in both classes well deserved them. The cup Whiten a healthy and well-shown pen, but we should certainly like to see their fobus less yellow. Any Variety class.—First good falkins. Deprived of their classes filkins seem successfully to have asserted themselves of late in the variety class. Beassest.—First good falkins. Deprived of their classes filkins seem successfully to have asserted themselves of late in the variety class. Beassest.—Gene Bantama have made a great descent from what they were a few years ago. In form it is true they are more game, but their colour to very poor, and their legs seldom match. This was the case with the interprise of in the first price for eige than we have seen the part of files. Any other Variety—First filters—lead, fairly marked birds, and better for eige than we have seen of late in the work of the point of the

RECENT ORNITHOLOGICAL SHOWS.

RECENT ORNITHOLOGICAL SHOWS.

Two important ornithological shows have been held during the past few days, both of which we had the pleasure of wincesing. The first took place at Burton-upon-Trent, where there were upwards of 1900 entries of Pigeons, Babbita, Canaries, Mules, and British and Foreign birds exhibited, besides a competition attiffed specimens. The Show was a good one and fairly managed, accepting that we could not get a glimpse of a catalogue during the whole of the first day, which we looked upon as a great mistaka. Satting aside this drawback the Show would have passed off well had it not been for an "unfair transaction" as a contemporary says, which occurred with certain noted exhibitors of Rabbits, who countenanced the lending and changing of certain specimens for the purpose of winning a "special prize of £3 St.!"

The Chronicle does not at all scruple in mentioning the names of the culprits, one of whom is a member of the Burton Committee in the culprits, one of whom is a member of the Burton Committee. the culprits, one of whom is a member of the Burton Committee ! We have it upon good authority that there will be no more open Rabbit Shows in connection with the Burton Ornithological

Society. Norwish filtow is one of those interesting events always looked forward to with pleasure by those moving in the world of Canarydom. It counts its seventh annual exhibition of the Norwich Alliance and Hast Anglican Ornithological Association, and the Show we again had the pleasure of participating in was possessed of as much attraction as any of its predecessors. The number of exhibits reached about 1100, and comprised Canaries of high and low colour, and such a fine collection of Lizards, Crested and Mules, rarely seen at one show. The competition in most classes was very severe. Besides the above British and Foreign burds and stuffed specimens formed imposing features of the Show, and there was very very like the second of the Show, and there were likewise something to please entomologists in the way of butterlies, moths, and beetles, of skry different varieties from the Bast Indies, in the largest case we ever saw, and which was values at £105, the owner being awarded a gold medal.

VARIETIES.

THE Poultry Club offer three prizes of £8, £2, and £1 for the best baskets for the conveyance of poultry to shows, to be com-peted for at the Crystal Palace Poultry Show.

— We hear that the famous White-created Polanda, also the Jacobias and Pigeons, of the late Mr. Thomas Norwood of Salisbury, are all for sale. The collection of Polands is a splendid one, and a rare chance for a beginner in the bread.

— At Oxford the entries of poultry there are not so good as last year. Those of Pigeons are better—vix., 1200. Of the latter neither the Carrier, Pouter, Turbit, or Jacobin classes are well filled. Autworps and Magpies are very numerous.

— At the Altrincham Petry Sessions last week, Nathan Marton of Denton near Manchester was fined 6s. and costs for cruelty to a Hamburgh cock which he had exhibited at the Altrincham Show. A witness testified that the said Denton man brought the cock to the Show, and just before penning him removed a pin from his comb and a stiff bandage of string.

— THE British Bee-keepers' Association Committee Meeting was held on Wednesday, October 18th, Present—Mr. T. W. Cowan in the chair, Rev. G. Bartrum, Means, Abbott, Cheshire, Hooker

Hunter, and the Rev. H. R. Peel, Hon. Sec. The question of the publication of diagrams for lectures again came on for discussion, and a sub-committee was formed to obtain estimates and definite information. The balance in favour of the Association after and a sub-committee was formed to obtain estimates and information. The balance in favour of the Association after payment of all claims was, as shown by the monthly audit, £59 12s.

Kessers. Cheshire and Hunter reported progress of the "Cottager's Handbook," in preparation. The names of members in arrear with subscription was read. Mr. J. Garratt, Hon. Sec., of the West Kent Bee-keepers' Association, waited upon the Committee desiring the affiliation of his Association with the British. The Committee association with the British. ing the affiliation of his Association with the British. The Committee agreed that the county of Kent might be advantageously worked from two centres, and admitted the West Kent Association to affiliation as a county association. Messrs. Cheahire and Hooker proposed and seconded that the Honorary Secretary be requested to draw up a form of recognition of county associations by the British. The Bev. E. Bartrum brought forward at some length a scheme for obtaining Government recognition of the claims of apiculture in the work of national education. The discussion of this question will be resumed at a future meeting.

WE hear that a three-guinea cup has been given by Mr. W. O. Hodges for Japanese Bantams at the forthcoming Crystal Palace Show. The Committee will provide second and third prizes, and we hope to see a large class of these quaint little birds.

— WE continue to hear of poultry, both prize-bred and birds of pure strain for profit, being exported to the New World. We learn that some Game, which have of late been carrying all before them at shows in the United States, came from the yards of Mr. S. Matthews. Some Dorkings from the yards of Mr. O. E. Cresswell have this week been shipped from Liverpool, destined to be the progenitors of improved farmyard stock in the River Plate.

Plate.
— SUCCESSFUL breeders of fine table poultry, as well as mere funciers of form and feather, are this year to have their reward at the Crystal Palace Show. It is announced that the proprietors of the Live Stock Journal have given two three-gunea cups for the heaviest cockerel and the heaviest pullet, either pure or cross-bred.

heaviest pullet, either pure or cross-bred.

— A MERTING has been held at the Agricultural Hall, London, relative to the formation of a British Goat Society. Mr. W. Freeman presided. Mr. H. Holmes Pegler explained that the objects of such a Society would be twofold—namely, to improve the breed of goats, and to encourage goat-keeping generally. The number of goats exhibited at the first dairy show was only twelve, whereas there were now ninety-five shown. The only thing now remaining to be done was to agree upon a certain standard of excellence, and to endeavour to breed up to it, the chief point at which to aim being good milking qualities. He suggested that the new Society should offer prizes at the shows of the Boyal Agricultural Society and similar bodies. After some discussion it was unanimously resolved to form an Association, to be called the was unanimously resolved to form an Association, to be called the British Goat Society, Mr. Pegler being appointed Hon. Secretary. The annual subscription was fixed at 5s., and most of those present enrolled their names as members.

CONVERSAZIONE OF THE BRITISH BEE-KEEPERS' ASSOCIATION.

MR. COWAN'S WINTERING PRAME (Illustrated)

THIS gathering was hardly so numerously attended as the similar previous one, though it cannot by any means be said ether to have lacked in interest or spirit. Mr. F. B. Jackson of Slindon being voted to the chair, Mr. Cowan rose to read his paper on "Wintering." Having laid down the general principles upon which successful wintering in the open air depends, Mr. Cowan proceeded to explain that large colonies are necessary because if upon which successful wintering in the open air depends, Mr. Cowan proceeded to explain that large colonies are necessary, because if the bees be few each is called upon to produce much heat, and in consequence to consume much honey and to pass through excessive labour, and as a result abnormal distension supervenes, often passing into dysentery. He pointed out that the general consumption of stores in a large frame hive from October 1st to committee of stores in a large frame invertion October let to lat of March is 1½ oz. daily, or something less than 13 lbs. of honey; but if bees, upon the supposition that this is enough, be left poor they were in constant unrest and anxiety, always rushing from the hive in the endeavour to make up deficiency, and in this way suffered more in wintering than their better-provided neighbours. suffered more in wintering than their better-provided neighbours. Winter passages were important, for if these were omitted bees unable to get round the cold edge of this comb might starve with abundance of stores in the next comb but one to them. To successfully winter, Mr. Cowan added, it is most important that the bees in each hive should be young at the close of the season—i.e., that breeding should be kept up late, and this can be brought about only by stimulative feeding. He explained that he had found in using the quilt that if it were allowed to hang half way down the hive side capillary attraction would draw off the moisture from the top of the hive and keep it in fine condition. He commended hives with double sides as better preservers of heat, and spoke of the good stocks usually made by condemned bees because of their late breeding. In mentioning the poisonous nature of carbonic acid produced by the breathing of the bees, and the necessity for ventilation, he introduced a frame which he explained had been used in a stock which had passed last winter drier and in better order than any other he nossessed.

possessed.

Of this frame we give an illustration with the spirit of Mr Cowan's explanation. One of the ordinary comb-frames is fitted up with a small metal pipe, one open extremity of which, A, passes out at the hive mouth. This pipe leads to a flat tin box, B, around which the bees are forced to cluster as the frame is put into the centre of the hive. The heat from the bees warms the box and its contained air, which ascends and passes out into the hive at C and D, the heavier consumed air sinking to the floor. In this way a constant supply of pure air is kept up, and the mouth of the hive may be made so small that only room for a passing been need be allowed. The tube, E, F, has at its lower end an inverted funnel, while F passes out through the crown board or quilt and materially assists in getting rid of vapour and foul air.

Hvely discussion was then commenced by Mr. J. Hunter

Fig. 36.

making some observations as to the period during which bees

making some conservations as to the period during which bees abstain from brood-raising.

Mr. Cheshire explained somewhat fully some discoveries he had made with regard to artificial feeding, but as this will be made the subject of an article it is needless to say more respecting

Mr. Giennie pointed out the necessity to screen bees from the sanshine of winter, which often tempts them to fly to their destruction. He placed in front of each hive-mouth a sheet of tin held in place by a common paper clip, and this saved the lives of

many bees.

many bees.

Mr. Abbott drew attention to a plan for protecting bees from draught by having as it were a front parlour to the hive; they living for the time being in the back. Mr. C. Stevens stated that he felt nervous in advancing the statement as a comparatively young bee-keeper; but he believed he had found the means of preventing propolising, and gave some instances in which he had actually placed edges together in hives which the bees had not fastened. Mr. Stevens would do service by showing his examples at some gathering, when the bee pundits will soon settle whether he has really solved the problem. Mr. Lyon questioned whether pollen was essential to the production of broad, but Messrs. Hunter and Cheshire on practical and scientific grounds put the affirmative conclusively.

Hunter and Cheshire on practical and scientific grounds put the affirmative conclusively.

The animated debate had been long continued when the Rev. H. R. Peel humorously remarked that he, rather as looking after the bee-keepers than the bees, reminded all that it was getting late. A warm vote of thanks to Mr. Cowan for his valuable paper, and to Mr. Jackson for filling the chair, terminated the proceedings.

PREPARING BEES FOR WINTER.

METHODS OF FEEDING.

GRIM winter is giving now unmistakeable signs of its approach, and no time is to be lost in getting bees into such condition as to enable them to meet all the rigour that may await us without any subsequent attempts at assistance on our part. The prime necessities for the season of repose—and the more complete the repose the better for the stock—are sufficient food, ample protection from cold and damp, and wisely managed ventilation. If these points are all settled as it should be we can hardly fail to bring our bees in admirable order into the spring.

these points are all settled as it should be we can hardly fail to bring our bees in admirable order into the spring.

I wish now to say something of methods of feeding, leaving till a future issue the questions of protection and ventilation. The owner of the skep often asks anxiously. How am I to feed my bees? my hivee have no holes at top. The answer clearly is, if you desire to feed above by the bottle, and no method is equal to it for the careful bee-keeper, make a hole in the top of your skep, and to accomplish this proceed thus:—With some means of preducing smoke—your tobacco pipe if you please, or a roll of old cotto-t (not lines) rag, or a torch made by twisting up some

corduroy, or best by one of these latter substances smouldering in a Bingham smoker—approach your skep, and commence to cut with a sharp narrow-bladed knife the hole where desired. When you have really penetrated "the honeyed dome" (it may not even be "honeyed" after such a summer) keep the bees in check by puffing at them as required. The hole complete, place over it a previously prepared thin board, not too small—as, though it is to carry a food bottle only now, it may take a super in summer. The board will have had made in its centre an aperture the size of that cut in the straw, and at its corners four hole sto take long screws, which if turned into the skep itself will hold with sufficient firmness. If nothing be placed between the board and the hive firmness. If nothing be placed between the board and the hive heated air will constantly flow away, to the immense detriment of the bees. To prevent this, before putting the board in its place lay a ring of tough dough, or, if you object to the dough, kneaded clay, round the hole in the hive, and squeezing the board down upon it an airtight joint is made which will remain intact for years. Having now our feeding stage the most simple method is to fill a pickle bottle with syrup, and tie over its neck a piece of fine canvas or coarse holland. An indiarubber band slipped over the neck will fix more quickly and neatly than tying with string, placing the palm of the hand over the cover, inverting the bottle the hand may be removed without a drop of the sweet liquid escaping, and this now stood upon the hole will be sipped out by the bees, whose long tongues will be thrust up through the pores of the canvas, air entering bubble by bubble as the feeding proof the canvas, air entering bubble by bubble as the feeding progresses. But if no care be taken to prevent it stranger bees will gather in a thick roll round the bottle neck on the outside of the hive, and not only will our help in large part go to those for whom it was not intended, but robbing is likely to be started. A flower pot or a pickle jar inverted and placed over the bottle will protect it, but falling such as these a common duster loosely tied in a knot round the neck and pressed against it will keep all uninvited bees

Having now described primitive methods within the reach of every thrifty cottager—and those that are not thrifty ought not to keep bees, for if they do the bees will do little towards keeping them—let me go on to describe others. It is well known that some years since I drew attention to the advantages of slow continuous feeding, and devised then a rotating stage of vulcanite, which permitted a regulation of the amount of food taken by the bees. This stage has been largely imitated by others, but I am not acquainted with any form equal in simplicity and effectiveness to the original, except a stage and bottle devised by Mr. Green of Rainham. My own has been long before the public, and is explained and illustrated in my "Practical Bee-keeping," so that now I shall content myself with describing Mr. Green's arrangement. A wide-necked bottle has a ring of box wood fitted accurately to its neck, and on to this ring is fixed a plate of vulcanite pierced with a number of small holes arranged in a particular pattern. When the bottle is filled with syrup the ring and vulcanite plate are put over its mouth, the box wood gripping it every thrifty cottager-and those that are not thrifty ought not to vulcanite plate are put over its mouth, the box wood gripping it vulcanite plate are put over its mouth, the box wood gripping it sufficiently to prevent its falling off when the bottle is inverted, the food not running out for reasons all will understand. A second vulcanite plate, also in a ring of box wood, is placed over the bees—i.e., over the feed hole, or over the opening in the quit. This vulcanite plate is also pierced in a particular pattern, the holes in it being larger than those in the one formerly mentioned. The bottle is stood in position, the two vulcanite plates touching faces. Where the holes lie over one another the bees can pass up their properties and drink in the awests: where they cover one faces. Where the holes lie over one another the bees can pass up their proboscides and drink in the sweets; where they cover one another this is impossible. A series of figures are placed on the edge of one box-wood ring, an index on the edge of the other, the index always standing over the figure cerresponding to the number of holes open. We thus at a glance see how rapidly it is possible for our bees to feed. We can increase or decrease the rate in a moment. The wood ring protects absolutely from robbers, and so perfect is it in this respect that even ants find it impossible to get at the sugar. This bottle received a special impossible to get at the sugar. This bottle received a special prize at Plymouth, and is in my opinion the most perfect feeder we yet have.—F. CHESHIRE, Avenue House, Acton.

FOUL BROOD.

I CONSIDER it a mere fancy of your esteemed correspondent, "B. & W.," that foul brood is in any way connected with the importation of the Italian bee. That disease popularly styled "back-gaun brood" was well known in Scottish apiaries long before the Italian bee was heard of; and "B. & W." forgets that the late Mr. Woodbury publicly acknowledged his indebtedness to Bonner's work published last century for enlightenment as to the nature of the malady he had to grapple with in his "dwindling apiary." Private correspondents of the late lamented gentleman are alike aware that foul brood found its way among his stocks solely in and through the combs of an English cottager's skep, and was not in any way connected with his Italian importations. All practical apiarians familiar with the case with which foul brood can be induced and the contagion spread must thank "B. & W." for his timely warning to the uninitiated to be aware of stranger bees and combs.—W. J. I CONSIDER it a mere fancy of your esteemed correspondent,

OUR LETTER BOX.

RABBITS' HAIR CLOTTED (E. P. N.).—Wash out the clots with soap and water, then keep the rabbits in a warm outhouse until they are thoroughly

dry.

CANABY IN A SLOW MOULT (Lizste).—Under the most favourable chi CANARY IN A SLOW MOULT (Listle).—Under the most favourable circumstances the moulting suckness is very trying to Canaries; but especially to those passing through a slow monit, such as yours appear to be, the sickness is worse, particularly at this period of the year. The bird falling off its song is not to be wondered at. Most likely it will break into song when the sickness has absted. A slow moult has a tendency to bring about irritation—thus one cause of the bird pecking itself. Are you quite sure the bird's cage is free from parasites? A flight for a few weeks in a spare room or spacious cage away from the heat of the fire, with a daily cold bath, fresh green food, salt to peck at, and plenty of sand to dust in, will do wonders in restoring the bird's health and appearance. Before you again place the Canary in its cage let the cage be cleansed, and examine well the crevices to see if there are any insects about.

FOUL BROOD IN ABBRDEEN AND BANFFSHIRE (J. S., Cairnic).—We are sorry to inform you that the comb sent is really foul-broody, and especially sorry to hear that many hives appear affected in the same manner. We can only commend to you the instructions already given, which we hope may

only commend to you are institutions arrestly gives, which we may assist you to a cure.

Uniting Bebs (J. W. Lanford).—In uniting swarms it is wise to use some strategic measures before the bees are cast together. Bees do not like strangers, and naturally treat them as enemies, naturally kill all intrusionists, and hold their own territory inviolate. This is well known, and also the fact that bees know each other and strangers by smell. Hence it is necessary in uniting swarms to put by some means the defenders off their guard, or take their city by surprise. Probably you took no precautions in your unsuccessful effort to unite two swarms. Feeding well and sprinkling both swarms with good minued syrup an hour before the union is attempted is an excellent way. Good feeding fills the defenders with joy and good nature, and makes the bees to be surrendered more acceptable to them. Another successful mode of uniting bees is to drive both swarms into separate empty hives and let them remam for an hour or two, then cast them together amongst the combs of the hive to be kept for stock. Thus both swarms are put to a disadvantage and feel as trepassers do, and act as if they had nothing to defend or care for but their own personal safety. Good feeding with scented syrup is important. The value of an extra swarm to a stock is so great that every precaution should be used to effect a happy union.

FOOD FOR BEES (A Subscriber).—You must lose no time in feeding your

FOOD FOR BEES (A Subscriber).—You must lose no time in feeding your bees, and you must feed liberally if you wish to save them. Barleysugar is not only too expensive, but bees do not take it down fast enough at this time of year. We have found good moist sugar at \$2d\$, or 3d\$, per fb, an excellent food made into a not too thick syrup by stirring till dissolved in beiling water. One pound of sugar to one plut will give about the suitable thickness for this time of year. Some persons boil the water, which we find unnecessary. Feed till your stocks have increased ten pounds in weight each.

each.

VARIOUS (A Constant Reader).—1, It is not good to let supers with comb in them remain over the stocks unless you close the communications, otherwise the combs get mouldy from the damp arising from the perspiration, &c., of the bess below. 3, The hives full of comb out of which your bess have died will do again if you can keep them in a dry place during winter that off from dust and waxmoth. We should out away any very old comb or any that contained dead bees; if the hives are fresh and clean next spring they will do to put swarms into. 3, New hives nevertheless are better than old ones. 4, Continue feeding your bees in mild weather till you have brought the weight up to 25 fbs. each, or till you feel satisfied that each stock has at least 10 fbs. of food to begin the winter with. Weight them again in the spring, and if you find the hives greatly reduced in weight when March comes begin then to feed again, or earlier if necessary. It is difficult to say when to stop. We are always guided by the weather and the condition of the hives at the time. when to stop. We are the hives at the time.

From observations taken near London during forty-three years, the average day temperature of the week is 53.7°; and its night temperature 37.3°.

THE CULTIVATION OF THE GRAPE VINE.
[Read before the Sheffield Gardeners' Association by Mr. ABBOTT.]

RAPES justly rank high among dessert fruits, and are always greatly appreciated both by the healthy and the invalid. In most cases I would impress upon intending cultivators the importance of preparing a good border, as a few pounds judiciously spent on that work will give good results and satisfaction in after years. For the staple soil I recommend

the first 3 inches, or 6 if the soil is very good, from the top of an old pasture. The turf may be used as soon as cut, but I prefer it stacked up for a few weeks. If used fresh it is liable to heat if there is much grass on it, and then often becomes much too close afterwards; it is, therefore, a wise precaution to stack it and to turn it over once, when the other materials necessary for the border can be added. One bushel of inch bones should be mixed with every two loads of soil, also add plenty of lime rubbish from old buildings, and oyster shells. Exclude all woody matter, as it is liable to produce fungus. The oyster shells should be broken or calcined, and are then very valuable. Some horse droppings or decayed cow manure may be employed; yet the border must not be made rich, as manure can always be employed in the form of top-dressings to maintain the vigour of the Vines. The bottom of the border should be concreted and well drained. This is an important matter and should not be neglected, as the Vine requires much water, and the soil must at the same time always be in a sweet healthy state. Concrete, however, will not be necessary in all cases, for some situations are suitable without it. Place a foot depth of rubble on the concrete, with drain pipes at intervals across the border, having a sharp fall into a drain at the front, and protect the drainage with a layer of turf, grass side downwards, then fill in with the compost. The border should not be less than 2 feet deep and from 10 to 20 feet wide.

The Vines should be planted 4 feet apart when they have commenced growing naturally in the spring without firing. Choose Vines with well-ripened wood, turn them out of the pots, and spread the roots out their full length, not leaving them in a ball; then cover them with about 6 inches of the best compost, mixing with it some ground or dissolved bones, pressing the soil, which should be moderately dry, rather firmly, then water with a fine rose. Do not prune the Vines at planting time, but allow them to break and then rub the buds off to the part where you want new canes to commence. Allow the young growth to advance until there is plenty of foliage, when the old can be removed without fear of bleeding. Afford no fire heat until the autumn, and let the Vines grow to the top of the house without stopping the leaders. Encourage all side shoots, and allow them also to grow without stopping until the house is quite full of foliage without crowding. Do not allow any fruit the first year, or it will seriously weaken the Vines and endanger their future prosperity. They should be trained to wires 18 inches from the glass, which distance I find quite near enough. Syringe in the afternoon

on fine days, and close as early as the situation of the house will allow. Employ fire heat to ripen the wood in the autumn if necessary, giving plenty of air both day and night; I find that one load of fuel then gives better results than two would do in the spring. After all the leaves have fallen prune without delay, and cut the Vines down to within 3 feet of the bottom if they are strong; the second year they may bear one or two bunches if only to prove the varieties, but do not overcrop, as a little indulgence when the Vines are young will be amply repaid in the future. Shorten the canes each year, leaving 3 or 4 feet of new wood, so that rods 18 or 20 feet long would take about six years to establish. I advocate and adopt the system of short-spur pruning—that is, cutting all side shoots on the main stem back to one eye, as it is neat in appearance and the flow of sap regular; but if I found when pruning that the wood was not satisfactory (it should cut like a piece of Oak), I should leave two eyes and rub off the extra one in spring, so as to have a double chance of fruit. The spurs or side shoots should not be less than from 2 to 3 feet apart. I prefer the latter distance, more particularly for Muscats, or any white Grapes; but instead of rubbing off all the buds between the spurs allow a few to remain and pinch them to two or three leaves; by this means the main stem will be nearly clothed with foliage from the base to the top, which will greatly assist the equal swelling of the main stem.

The leading shoot I always allow to grow every year to the top of the house and down the back wall before stopping. The side shoots I usually stop the second leaf beyond the fruit; but if there is room they may produce five or six before stopping. The sub-laterals I stop at the first leaf, and if it can be done without crowding another leaf or two may be allowed, as with plenty of good and clean foliage well exposed to the light you will have healthy root-action, which is necessary for the proper finishing of the fruit. The house being now full of foliage, stop every lateral as soon as it shows itself. By this time the Vines will be in bloom and will require a high and rather dry temperature of 75° to 80° by day. Allow the temperature to rise to 90° or even 95°, with sun and plenty of air. Shake the Vines when in bloom by gently tapping them with the hand to disperse the pollen. I also generally use a rabbit's tail fixed on a stick and lightly stroke the bunches with it, which carries the pollen very well and assists to impregnate the blossoms. This is very necessary with many varieties, particularly Muscats. After the Grapes are set commence thinning them as soon as possible; to do this well requires practice, but a bunch to look well on the table should be firm enough to retain the shape it had when hanging on the Vine. Do not handle the berries, or the effects will be seen afterwards in the form of rust, and will spoil their appearance. At this stage do not syringe the Vines until the bunches are thinned and thoroughly cleaned from dead flowers, or the water will stain the berries. I usually syringe the Vines once a day, except when in flower or the weather is dull, until the fruit commences colouring, closing the house early to obtain all the sun heat possible with safety. At night when the fires are made up the top

NO. 1622.-VOL. LXII., OLD SERIES.

NO. 970-VOL. XXXVIL, NEW SERIES.

ventilators are left open about an inch. After the fruit has commenced colouring syringing must cease, and the house should never be entirely closed again neither front nor top, always allowing as much air as possible when the temperature can be maintained at 80° to 85° by day and 65° to 70° by night. Some gardeners never syringe after the fruit is set, but I am obliged to do so to prevent red spider; but if plenty of mois-ture can be maintained by evaporation and damping without syringing to keep the Vines clean and healthy it must be a decided advantage to the finish of the fruit.

After the fruit is set give good soakings of tepid liquid manure not too strong, every two or three weeks until the fruit commences to colour. I usually employ the drainings from a liquid manure tank belonging to the stables and cowhouse, but sometimes I use fresh horse droppings put into tubs and scalded, applying it at a temperature of 80° or 85°; both the liquid and the manure are spread evenly on the surface of the inside border. I find this one of the safest of manures; but it is best to give the Vines a change. I have used Amies'

chemical manure with good results.

When the Vines are pruned all loose bark is removed by rubbing with the hand only; the rods are then washed with warm water and soft soap, and are painted with a mixture of Gishurst compound, soot, lime, and clay, with a little sizeing to make the paint adhere to the stem. The top soil and old manure are then taken off down to the roots, and a top-dressing of fresh loam mixed with old hotbed manure, burnt ashes, and dissolved bones is given. The Vines are then laid horizontally on the front of the house, and remain there until they commence growing in the spring. The outside borders, after they have received a good soaking of rain in the autumn, are covered with portable glass frames, which remain on until the end of May or first week in June. Roots in outside borders have the advantage of the summer and autumn rains, and I always find more roots close to the surface of those borders than I do inside the house. A covering of long litter about a foot in depth is useful for the border when glass or shutters are not provided. To do justice to a Vine border it should never be dug nor cropped, but should have the full influence of the sun.

If old Vines are unfruitful or not satisfactory take all the old soil off down to the roots and raise them; cut a slight notch in the old roots at distances of 12 or 15 inches apart, which will cause new roots to issue from the parts cut, then cover with fresh soil, the same as recommended for the borders. Nothing suits Vines better than new soil. When the Vines commence growing, instead of keeping the old rods rub all growths off to the bottom and take up a young cane to the top of the house. If the roof is lengthy it is best to take two canes; commencing the other half way up, let the old rods hang down, and rub all growths off as soon as they appear, they will keep growing, but rub the shoots off and let the sap flow into the young canes, which will soon grow to the top of the house. When the house is full of foliage cut the old stems away by a little every day until they are cut clean off, they will not bleed if care is used not to cut them off too soon. Attend, then, to the proper ripening of the wood, and the Vines should fruit well the following season.

The varieties I recommend for general cultivation where

plenty of fire heat can be employed are Black Hamburgh, Muscat of Alexandria, Madresfield Court, a great favourite of mine, good in all respects; Bowood Muscat, Black Lady Downe's and Black Alicante: plant plenty of these, and you will have Grapes that will give satisfaction. For amateurs, where little or no fire is used, Black Hamburgh, Foster's White Seedling, and Royal Ascot, a good Grape that will ripen and

colour well in a cool house, are suitable.

AUTUMN FLOWERS.

THIS autumn we have had the only fine weather that we have been favoured with this year. October has been a dry month, but Roses have not done much in the way of producing second blooms. It is true I have not a large collection, but those I have are for the most part now flowerless. Baronne de Rothschild is with me the best for flowering in autumn, and La France comes next. The Teas this year have not as yet bloomed at all. Marie Van Houtte used to flower most profusely late in the autumn, but I have not seen a bloom this year since July.

The Gladioli have been exceedingly fine. I have only French varieties, but a great amateur florist who called here said he had never seen finer spikes. Among the crimsons and scarlets

Meteor is a very fine variety; while Maréchal Vaillant is a very bright scarlet blotched with white, a truly grand flower. Among the lighter shades of red and rose Sir Joseph Paxton, Ninon d'Eclos, Molière, and Madame de Sevigné are all good Perhaps one of the best of the purples is the one dedicated to the illustrious Italian musician Cherubini, while Dr. Lindley and Le Dante are both fine; Mozart is also worthy of its great name. Among the whites we find the finest spikes; the petals are larger, the flowers finer, and the effect most delightful. I do not know of a pure self-white, but Canova and Norma are both very good. The yellows at present are weak—in fact I do not know of a really good yellow; perhaps a warm buff is nearer the colour of most varieties than yellow. The best I have are Canary and Sulphureus.

I have now a fine collection of herbaceous Asters, or Michael. mas Daisies, blooming in the churchvard. These are excellent decorative flowers, far superior, in my opinion, to the majority of Chrysanthemums. They are very vigorous-growing plants, requiring plenty of room. Among the best are cabulicus, beautiful light blue; grandiflorus, purple; laxus, bright lavender; alpinus albus, lavender-blue. The herbaceous Phloxes are now exceedingly fine. There are hundreds of varieties of these splendid flowers, and it is difficult to select any without doing injustice to others; but The Bride, La Perle, Atalanta, Dame Blanck are charming white varieties; and J. K. Lord, salmon red; Baron Duruffe, rich purplish-crimson; Gloire de Porteau a rosv

lilac, are all good here.

Perhaps the gayest time of all here this year has been September and October. The Gladioli, Phloxes, and Asters are so gay and present such bold masses of colour that the garden may be seen bright with flowers from a long distance. Chrysanthemums are not yet in full bloom, but the stalks are full of buds, and these, to me most melancholy flowers, will soon carry on the succession and give us a few ragged flowers as long as the frost will allow them to bloom. The trees here are (October 21st) only just beginning to change colour, and pheasant shooting has not even been attempted. There is a great amount of food for stock in our fields, and everything looks as if we should have a long and fine autumn down west. WYLD SAVAGE.

THE ROSE ELECTION. GARDEN VARIETIES.

AT least with this portion of my rosy task I anticipated but a small amount of difficulty. I fondly imagined that I should find that even if the men were numerous the opinions would be comparatively unanimous. Alas! alas! as I write these lines, with only a portion of the voting papers returned, I have nevertheless already tabulated over two hundred different Roses, and still I may add, in the words of the old song, "They

come, they come!"

What points, it may be asked by some, are necessary for a garden Rose to be considered A1? There are, it seems to me, two great essentials-vigour of constitution and abundance of bloom, and if this abundance of bloom can be spread over a duration of time so much the more is the value of the variety enhanced. Some of the summer Roses make up, it appears to me, by their profusion of flowers for the complete absence of bloom in the later months; but I think the result proves that but few of the other voters agree with me, or the position of the summer Roses would be higher; yet few, I apprehend, can have seen a plant of Charles Lawson, for instance, covering some 8 or 9 feet square of a wall, the luxuriant foliage interspersed with a hundred blooms, each vieing with its fellows, without exclaiming at the glory of the sight, and allowing that numbers certainly made some amends for the short-lived

I cannot say whether this peculiar season—which, whatever may be its faults, has at least allowed us to see some of the blooms of our favourites in great beauty-has altered the character of some of our Roses, but 1 never recollect seeing & bloom out on a Hybrid Bourbon Rose late in September before. but two or three days ago in September I found in my garden

a stray bloom on a plant of Madame Barney.

A few of the electors appear to me by their replies to have considered that the question referred rather to the best garden flowers among the more "exhibition" Rosels indeed, one person declined to vote because he should only be giving the names of best-blooming exhibition varieties. I think the names of best-blooming exhibition varieties. I think the qualities necessary in a garden Rose are very different; and though on starting this "garden election" I felt convinced

that not a few of those that figured amongst the highest seventy would also be returned as amongst the most valuable garden flowers, yet at the same time I felt equally certain that the shifting of position would be considerable, and that some unplaced would on this test find their way into the charmed circle. I can well understand a person selecting thirty garden Roses choosing some amongst the number for beauty of form, although in the general number masses of bloom, with little consideration for beauty of outline, would probably guide our selection. With many persons variety in the character of the Rose would also have a certain weight; to such persons an attentive consideration of Mr. Cranston's list will be valuable, and for the same purpose Messrs. Ewing's list will repay attention. These two lists may be usefully published in a future number. But the table will speak for itself, and it may satisfy the curiosity of some of our readers. The two classes of voters have been kept distinct, and the headings of the columns are the same as those of last week (page 322).

Thirteen other Roses obtained five votes, twenty were mentioned four times, twenty-six three times, two votes were given to thirty-six other candidates, and, to complete the list, eighty-one obtained honourable mention only once out of 235 Roses named altogether.

The first return I received from a well-known contributor to our columns ("A. C."), and he said he anxiously expected the poll, and fully anticipated a large number of solitary mentions. His prophecy is correct. I confess not to have expected anything approaching the number of Roses to have been named. Now, I venture to say that had I asked the electors to name

the Rose that would head the poll they would not have named La France, which is at the head of the list by a very large majority. Some years since in reply to my question (name the best Rose in cultivation for all purposes) the verdict was unhesitatingly in favour of Gloire de Dijon, and the next on the list was Maréchal Niel. I believe the reply would be the same still. How, then, arises the position? From examining the returns I am forced to conclude that some of the electors considered Teas inadmissible; at any rate, no tea aroma can be detected in their selection. I felt, however, it was not my duty to put leading questions as to the Roses, as the question certainly included all Roses.

The extraordinary way in which the two premier Roses stand out is most curious, as the lowest of these has thirty first-class votes; Duke of Edinburgh, the third highest in these votes, can only muster thirteen. There are in all thirty-seven electors (twenty-five amateurs and twelve nurserymen—nearly two to one), but the leading Rose was omitted altogether by three electors, and Gloire de Dijon by six! Further, one would suppose that the twentieth Rose on the list would have polled at least half the highest possible, but, on the contrary, it falls far short; indeed, the rapid diminution of the grand total is something very extraordinary. Maréchal Niel, it will be noticed, has but eleven votes, but then they are all first-class. Capitaine Christy, though having nine votes, has not a single nurseryman to say a good word for him.

Altogether I personally feel that this "garden" election is not a success as to our having arrived at the thirty best garden Roses. Perhaps I have no right to say this. I certainly shall not take the wind out of "WYLD SAVAGE'S" sails, and say that it is "a mockery, delusion, and snare;" but I believe that another year we should better understand what we are aiming at. Surely we need in garden Roses variety of form and colour, and the specimens we would like in our gardens need not be all giants, yet until we arrive at forty-seven we do not see a Rose named that is always small. So again No. 43, Coupe d'Hébé, the highest of the summer Roses, with a grand total of eight votes out of thirty-seven, shows how very differently we look at the value of that class of Rose for garden purposes. JOSEPH HUNTON Warminster.

rently we look at the value of that class of Rose for garden purposes.—Joseph Hinton, Warminster.

P.S.—I am indebted to Mr. Thomas Laxton for the following alterations and additions to the poll list on page 322, which makes it almost complete:—No. 14, Mdlle. Marie Finger, raised by Rambaux and sent out by Lacharme. No. 28, Constantin Fretiakoff, 1877; raiser, Jamain. No. 46, Madame G. Luizet, 1877; Liabaud. No. 48, Madame Welsh, raised by Veuve Ducher. This Rose I have seen in some of the lists classed as an English Rose. No. 53, Souvenir de Madame Pernet, 1877 (!), raised by Pernet. No. 55, Empress of India, 1874, raised by Mr. Thomas Laxton; and No. 49, Duchess of Bedford, was raised by Mr. R. B. Postans.—J. H.

THE TOMATO DISEASE.

For the last three or four years the cultivation of the Tomato in this neighbourhood in the open air has become an impossibility. As soon as the fruit begins to colour, and sometimes before, the haulm, and then the fruit, is attacked by a disease which seems to be almost identical to that from which its cousin german the Potato suffers; and during my visit to Fontainebleau I discovered that the same disease had attacked the Tomato there. Knowing how largely it is used in France and how very much more popular it is becoming amongst ourselves, moreover how wholesome it is, it seems a great pity that this hindrance to its cultivation should have arisen. I am afraid that, like the Potato disease, there is no prevention and also no cure. We may discover resting spores, but unless we can devise some plan of destroying them I do not see that practically the discovery is of much use.—D., Deal.

FUCHSIA RICCARTONI AT BOURNEMOUTH.—Seeing in the Journal of Horticulture, October 9th, page 289, some account of the extraordinary growth and luxuriance of Fuchsias in the Isle of Wight, and knowing that my Fuchsia Riccartoni plants on each side the drive to my house are the admiration and surprise of all who visit me, I last week had my largest measured. The diameter was from north to south 11 feet 6 inches, from east to west 13 feet 2 inches at 6 feet from the ground, and the height 10 feet 6 inches. Last year these figures would have been higher, but the intense frost of the past winter caught some of the top and outside branches and obliged me to cut quite 1 foot from the height, the sides also were cut back.

Had all these plants been left to Nature I could not venture to say what size they might have been by this. I have been obliged to cut all my Fuchsia Riccartoni back very much, as they had trespassed upon the drive, and space wanted for other shrubs, but in their trimmed and shortened state I am glad to report them in testimony of the fine climate we enjoy here.—A. M. C., Bournemouth.

FRUIT CROPS IN ESKDALE.

Grapes.—Our Vine borders are annually top-dressed with good compost. At the time of doing this last winter I added a good quantity of lime, slightly forking it in with the other ingredients, and the result this year has been very satisfactory; for notwithstanding the heavy rains and sunless weather all through the growing season, Black Hamburghs never coloured better. Duke of Buccleuch is still in my estimation a fine Grape and should be in every collection. I have it grafted on the Muscat. Venn's Muscat is a very productive good-flavoured Grape, and succeeds the Black Hamburgh very well if grown in the same house. Madresfield Court has done exceedingly well with me, and as I have recommended it in your pages before I beg to do so again, confirming all I have said in its favour. We have only one Vine of it, which has been fruited heavily every season since the second year it was planted. The average length of the berries with us are 1½ inch, and several of these exceed 1½ inch in length. It is certainly a noble Grape, and has a very pleasant flavour. With many growers it is subject to crack; to prevent this I recommend keeping it well supplied with water and occasional doses of liquid manure until colouring commences, when water may be withheld and a drier atmosphere maintained. Such is my treatment of this Grape, and which I find to answer admirably.

Peaches and Nectarines.—Of these we have had magnificent crops, and have gathered about 1400 fine fruits from the trees in the house. Dagmar, Royal George, and Noblesse Peaches have done best. The first-named was planted three years ago, and has proved a very productive fine-flavoured Peach; it carried a good crop last year, and this season it carried 120 splendid fruits. I recommend this variety to anyone who is contemplating planting. Duc de Tello (Dutilly's), Violette Hâtive, Pitmaston Orange, and Elruge Nectarines have done best with me. The three first are the best that I have tried both as to fruiting and other qualities. We annually top-dress our Peach border with some good rich compost immediately after pruning and washing the houses, never allowing the borders to become cracked or dry during the whole season; indeed, I generally give the border a good soaking of liquid manure after the crops are gathered.

Apples trees on walls are bearing a better crop with us than they have for the last two years. Pears are in a fair quantity on some trees, but very small, and many of them I fear will be worthless. Raspberries have been over an average crop, and have made fine strong canes. We have adopted wire trellises for supports, and find them a great improvement; we also mulch the beds freely with short grass throughout the summer. I may add that the Raspberries have been grown on the same ground for seventeen years, and are yielding as fine crops as ever. Black Currants and Gooseberries have been abundant; we only gathered the last of them about a fortnight ago. Red Currants have also been plentiful; we have still a few hanging on the bushes.

Strawberry plants have fruited well, indeed we have not had such a fine crop for some years. Those planted last autumn have done best, excelling the old-established plants both as to quantity and quality. The varieties grown are Sir Joseph Paxton, Garibaldi. James Veitch, President, Duke of Edinburgh, Duc de Malakoff, and Comte de Paris.—James Dickson, Arkleton.

GARDEN VERMIN.

Slugs.—The best remedy against slugs are ducks. Brewers' grains are a farce. Turn in the ducks early; keep them in during the daytime, and let them out in the evenings.

Scale.—The best remedy is methylated spirit laid on with a brush. It is the late Mr. Rivers' receipt.

Red Spider and Milder.—Place some naptha in water, and either syringe, or, what is better, sponge the trees. Last year my fruit trees under glass were badly attacked by red spider and mildew. As the winter was wet I set my men to sponge

the trees; consequently this year I have not seen a red spider, nor has there been any mildew. I had the house painted in winter.

Snails.—These in winter congregate and may be killed easily.

They get in large numbers under Ivy or any other shelter.

During a frost is the time to catch them.—W. F. RADCLYFFE.

CLIMBERS.

FROM the climbers round my own house there is a constant succession of bloom. On the south side an immense Magnolia grandiflors is this year loaded with bloom. The flowers open well too, and their delicious fragrance fills the house. They do not last long nor travel well, though some of mine go to friends in Scotland in the weekly hamper which makes a small return for the grouse which are sent down from time to time. Next to the Magnolia is a very fine yellow Jasmine (Jasminum revolu-tum), which has beautiful foliage and pretty yellow flowers, but they drop too easily, and their scent is what is commonly called "faint," and by no means pleasing. Beneath the Jamine a sturdy old Myrtle grew for many a year; it is now dead, but in spring a fine Everlasting Pea grows up, which is speedily covered with flowers, and then almost as speedily swept away altogether. Close to this is a fine young plant of Chimonanthus fragrans, which is doing well, and if the shoots ripen sufficiently may flower in the winter. Vesta grows by its side. I gave three times as much for it as for Miss Bateman, and I do not believe there is any real difference. If anything Miss Bateman has the advantage. A strong plant of Jasminum nudiflorum comes next—an invaluable climber; its long sprays covered with golden flowers at Christmas are most precious. By the side of this and amongst it grows Clematis Jackmanni. The dark purple flowers are certainly rich and velvety, but the recommendation to use it as a bedder seems to me a mistake. The flowers are late in coming, and do not last in perfection long. It ought not to be placed where the flowers are expected to make a show the whole season. A large space of wall is covered by the beautiful Trumpet Flower, Bignonia radicans. This plant is not nearly so common as it ought to be. The large bunches of long trumpet-shaped flowers, coming at the end of August, are a great addition to the wall garden. Nothing attracts so much attention, and few people seem to know it. It is cut-in quite close every autumn, and the flowers come at the end of the long summer shoots. It has the habit of what the poor people call "rasseling," so that offshoots may be found coming up in most unexpected places at a great distance from the parent, hence the name radicans. radicans. I recommend anyone who has a south wall for climbers to obtain Bignonia radicans, and they will enjoyafters while the quantity of blossoms which they will have from it in the autumn months.

Underneath this Bignonia and sheltered by it is a Climbing Devoniensis, sweetest of Roses, with a perfume which nothing else can equal. It does not grow strong as it would in the milder climate of the county from which it takes its name, but it always flowers, and lately it has shown a disposition to improve. On the same wall Maréchal Niel does splendidly, but it appears to me to be a Rose which soon exhaust itself by flowering. I do not think I shall ever again have from it the hundreds of blooms which once adorned its great thomy branches. Clematis montana, allowed to take its own way to

a great extent, hangs about in graceful festoons.

For those who like scented flowers few plants are better than the Stauntonia latifolia, the perfume of which is very strong. It is, perhaps, rather delicate, but it will grow, I believe, on any south wall. There is a curious old church at Ringmore, near the sea on the south coast of Devou, on the south wall of which there was, and probably there still is, a fine plant of Solanum crispum. The flower is very like the Potato, showing their natural affinity. It produces an extraordinary quantity of blossoms, and is certainly a very great ornament to the church when it is in flower. It is a plant not often met with, but one easily managed after it has once made a start. In that picturesque churchyard at Ringmore, amongst gigantic Fuchsias and many other flowering plants and shrub, with the wide expanse of blue sea, and the cottages of the village nestled in the valley below, this Solanum seemed quite at home.

There is something about Cotoneaster which I could never like. Just as Aucuba is associated with the town area steps descending to the kitchen, so Cotoneaster is associated with dusty roads. It always looks as if it had been suffering from

a recent shower of March dust. The berries are dull, the flowers inconspicuous; the whole plant looks like one of those things which have to struggle for life. It is not much cared for, no one gives it a thought; nevertheless there it is with its tough, wiry, leafy sprays climbing about and doing well. Passion-flowers might be much more common than they are, and it is a great pity that such an interesting flower should not be more cultivated. P. cærulea is almost hardy, though such a winter as last certainly did it much injury. It has rather an untidy appearance unless kept strictly in order. The fruit is curious, and some years very abundant. It grows in quantities on a row of houses on the outskirts of the south side of Dublin, called Pembroke Road. I remember many years ago that those houses were covered with the fruit of the Passiflora cærulea, and presented a striking appearance on that account.

cærules, and presented a striking appearance on that account.

If the comparatively new Virginian Creeper, Ampelopsis Veitchii, only grew a little faster it would be an invaluable climber for places where no nail can be driven. It clings and sticks fast to anything. I hope in time to get it to cover a new iron church which is simply hideous in its naked deformity, but clothed with this Ampelopsis might look quite

pretty .- A GLOUCESTERSHIRE PARSON.

WELLINGTONIA GIGANTEA.

On page 306 Mr. Muir inquires if it is usual for this tree to produce clusters of two dozen or more cones. It is very common with many trees here, and particularly near the tops, but some of the branches lower down have only six or seven in a cluster. The cones appear very persistent, remaining on the trees a few years before dropping off; but all attempts with me as yet to produce young plants from the seed, which is not unlike that of Parsnips, have proved futile. Some have been sown in a hotbed, some in a stove, and some under a handlight at the base of a north wall. One seed in the last sowing germinated and the plant grew about one-eighth of an inch above ground, but died in a few days after. Some seed that I have taken within this last month from a healthy tree about 48 feet high I have sown in a cool greenhouse for trial. If any of your numerous correspondents have been fortunate enough to raise plants from English-saved seed it would be worth recording.

A few of what appeared to be the highest trees were measured a few days ago; the tallest was 53 feet in height, girth at base 10 feet 8 inches. This tree lost its leader some years ago, or no doubt it would have been a few feet higher. However, another was produced, which appears vigorous, having grown 18 inches since this time last year. Another tree, 51 feet 6 inches high, has a girth at base of 9 feet 6 inches; but the tree here with the largest girth, 11 feet 6 inches at base, is only about 30 feet in height, although raised from the same batch of seedlings as the two above mentioned. They are growing in a loamy soil about 3 feet deep, with a stony or gravelly subsoil, but I have seen them thrive well on a clayey subsoil that is well drained; planting them in a poor shallow soil I

believe is useless.

There can be no question but that this tree will eventually make a fine landscape tree. It contrasts well with the Oak and Spanish Chestnut, and some Wellingtonias planted with young plantations of the above would in years to come make quite a feature in the landscape—that is, provided the soil was suitable. Their pyramidal tops resemble so many church spires, they occupy very little room; and as it is likely to prove one of the tallest of trees its effect over the tops of Oaks 60, 70, or 80 feet high in after years may readily be imagined. Some that are here, averaging 45 feet high, towering above such plants as Laurels, Hollies, Yews, Laburnums, and Evergreen Oaks that range from 20 to 30 feet in height have a very good appearance from a distance. As a timber tree it does not appear to be of much value; two or three trees 30 feet high that we have cut down show that the wood is very soft and coarse.—A. Harding, Orton Hall.

VEITCH'S AUTUMN GIANT CAULIFLOWER.—This is superior to any we have grown. I find that by sowing it in the open air we cannot have it fit for cutting in this locality until late in September, so that for the last two or three years I have sown a sprinkling of seed in a box and pricked out the plants into other boxes, growing them on in a cool house until we can safely plant them out. By this means we have them a month earlier than those sown outside. Some treated in this

way were cut the end of August this season, and a few fine heads are still at this date uncut. Nitrate of soda stirred in with the soil when hoeing is very beneficial.—JAMES DICKSON.

SHEFFIELD GARDENS AND GARDENERS.—No. 3. ENDCLIFFE HALL.

SIR JOHN BROWN'S residence, is situate on the same hillaide as Mr. Mark Firth's, and overlooks the same beautiful valley; but at Endcliffe art has been freely exercised in the ornamentation of the grounds, while at Oakbrook Nature has had but a modicum of assistance. The mansion of Endcliffe is an elaborate structure replete with every requisite both of an useful and ornamental nature that art could suggest and capital supply; and the appurtenances and the surroundings are

singularly complete and harmonious.

The sloping nature of the ground in front of the mansion suggested the ready formation of terraced and panelled gardens. These were designed with great taste by Sir John Brown, and the work was executed under his supervision. In the chief flower garden shrubs, flowers, statuary, and marble vases are pleasingly combined, no one feature unduly preponderating, and the whole amply relieved by lawns and Conifers, and near and distant tree-clad hills and verdant dales. In the flower beds dwarf shrubs, Conifers, and Heaths have permanent positions in the form of rings, margins, and central groups; flowers being planted in the spaces in spring and summer, and variegated and other shrubs taking their places in the winter; thus the garden is attractive at all periods of the veer.

But, perhaps, the extensive and well-arranged glass structures constitute the most notable feature of the gardens. There are twenty-two houses, some of them very large and lofty, and so arranged that they form a lengthy, varied, and beautiful promenade—not in a direct line, for they almost encircle a certain part of the garden contiguous to the mansion. The central block is very imposing. It is a large tropical house with two wings. The chief portion is 35 feet high, in the centre of which is a mound or large raised bed in which Palms, Dracemas, &c., are planted with an undergrowth principally Dracenas, &c., are planted, with an undergrowth principally of large-foliaged Begonias, with fine specimens at the corners of the elegant Fern Asplenium ferrulaceum. The effect of this arrangement is extremely fine. The Palms are splendid specimens reaching the roof. Seaforthia elegans is rarely seen in such condition, four remarkable clusters of flowers and fruit issuing from the stem, which impart to this noble specimen a truly elegant appearance. The seeds falling from the tree and settling in the moist crevices of the rockery germinate freely, producing numbers of young plants. Specimen Livistonias and Phœnix dactylifers are almost equally fine; specimens of Dracæna brasiliensis are 12 feet high; and a species of Bambusa has produced wonderful growths. At the north side of the wings raised beds have also been formed and planted chiefly with Tree Ferns, the ground being carpeted with Selaginellas, Fittonias, Tradescantias, and other suitable plants. The Tree Ferns are growing luxuriantly, and the entire asrangement is extremely enjoyable. In one of these structures Caryota urens is fruiting, as also is a vigorous specimen of Monstera deliciosa; Astrocaryum mexicanum is flowering, and the brightly coloured bracts of Musa rosacea contrast effectively with the noble foliage. A seedling form of Blechnum brasiliense with red-stemmed fronds is conspicuous. On the south side are many specimen stove plants of exhibition quality, and in a large plant of Platycerium alcicorne is a robin's mest in which young birds were reared, and from which they emerged in safety. All the specimens in this fine range of houses are in the highest possible condition, and the free and natural manner in which they are disposed enhances their beauty considerably.

Long ranges of glass are devoted to Peaches, some of the structures having rafters 22 feet long. The trees are very large, thinly trained, and healthy, and produce fruit 12 ozs. in weight. Vines are also largely grown and produce very heavy crops. A great number of medium-sized bunches being required, Mr. Stephens does not adopt closs-spur pruning, but trains-in young wood thinly, and thus ensures crops of great weight. In most of the vineries, early and late, Camellias are grown and trained to the back walls, and in some instances narrow beds are formed at the back of the inside borders next the paths and planted with Camellias. The Vines do not apparently suffer in the least, while the Camellias grow and flower with great freedom—in fact, blooms are cut in profusion from Angust in the earliest vineries, to June in the late houses.

Few plants can be cultivated under Vines more profitably than Camellias, and in few places are they better so grown than at Endcliffe Hall.

Houses are also provided for plants, including Orchids. The Orchid house is glazed with rough plate glass and never shaded, and the plants, owing to the growth being so well matured, flower with great freedom; but a little shading at times would improve the foliage. Several Orchids were flowering, including a good plant of Lycaste Skinneri alba. The Vanilla was also fruiting freely on the roof. Of the ordinary forcing houses it is not necessary to speak, except that in the Strawberry house Tomatoes were bearing a fine crop, an excellent lot of Strawberries being in readiness to follow at the proper season.

The kitchen garden is divided from the public road by iron pallisading, through which hundreds of "Sheffielders" criticise the crops, which with the general neatness of the enclosure will bear criticism, as, indeed, will every portion of Sir John Brown's well-appointed garden, as superior culture and excellent order pervades the entire establishment.

RIVERDALE.

Somewhat lower down the declivity above referred to, and nearer Ranmoor is this, the residence of C. H. Firth, Esq., a gentleman who evidently cherishes his garden, and has been fortunate in securing the services of a gardener of unquestionable ability in Mr. Abbott. The grounds though not large are of diversified aspect; the lower portion—the bed of the dale, through which a tributary of the river Porter rushes impetuously down its narrow bed under a canopy of foliage, being wildly picturesque. It was this wilderness that doubt-less suggested the name, a very appropriate one, for the estate; and it is this dale, too, rich in alluvial soil and the decomposed vegetation of ages, that yielded the compost which, with otherwise skilful culture, produces the splendid Grapes for which Riverdale is locally famed; justly famed, too, for better conditioned Vines and finer Grapes are rarely seen in any garden. The vineries, a light and admirably constructed range. are on higher ground, and it must have been a work of no small magnitude wheeling the soil for the borders up a hill so steep and so long: yet it was labour wisely incurred, when it is found that the average weights of the bunches of such Grapes as Black Hamburgh, Madresfield Court, Golden Queen, and Mrs. Pearson is each year 5 to 6 fbs., and of Alicante 8 to 9 fbs., excellently formed firm bunches of well-finished fruit, except as to one variety, Mrs. Pearson, which unfortunately rusts just as it commences ripening. The bunches of it are splendid, as it commences ripening. The bunches of it are splendid, certainly amongst the finest that have ever been produced, and the fruit is of superior quality and flavour, but marred in appearance by the rust. Golden Queen is fine and free from rust, but not quite free from the dark stain in the flesh (for it is not in the skin), that so often detracts from the appearance of this Grape, and it is not esteemed nearly so highly at Riverdale for flavour as is Mrs. Pearson. Mr. Abbott has detailed his practice in a paper published in another column, which is worth reading, as he is undoubtedly a master in the art of Grape culture, and it is not necessary to refer further to the subject here.

Equally well are Peaches and Nectarines grown in the same range. The trees are manifestly in first-rate condition, and, as I was informed by competent judges, invariably produce remarkable crops of fine fruit. At right angles with the chief range, and connected with it, are span-roofed houses for plants, also for Cucumbers and Melons. Of the last-named fruit the remnant of the crop of Riverdale Green-flesh was hanging—a particularly handsomely netted fruit of medium size, and esteemed for its rich flavour: it was raised by Mr. Abbott. A small, smooth, egg-shaped Tomato of firm flesh and good quality, also raised by Mr. Abbott, was producing a heavy crop in one of the houses. The ground having a very sharp slope these houses are erected on arches, the space beneath being utilised for Mushroom houses, root stores, tool sheds, &c., readily entered from the lower ground—a compact and excellent arrangement.

In the grounds adjoining a number of moveable frames, employed for protecting the Vine border in winter, were occupied with Cucumbers, referred to for the purpose of noticing two varieties that are considered specially adapted for this mode of culture—namely, Kelway's Prince of Wales and Myton Hall. They were bearing wonderful crops. The former is of the Telegraph type, and excels that variety for frames, but is not equal to it for cultivation in houses. Myton Hall is a very dark green fruit with scarcely any neck; it is of good

size and very prolific. Although not widely known, it is considered by Sheffield gardeners one of the most useful frame Cucumbers in cultivation. It is undoubtedly very good and apparently quite distinct.

An attractive and useful mode of growing Red Currants is also noticeable. The trees are standards, having stems from 3 to 4 feet high, the branches forming the heads being trained at regular intervals down umbrella-shaped wire trellises about 3 feet in diameter. The thin disposition of the branches, which receive all the light and air possible, not only induces great fruitfulness, but the crop hangs until the approach of winter, and is readily protected by hexagon netting, which is thrown lightly over the heads and secured to the stems. These umbrella-shaped Currant trees growing by the side of the walk are very ornamental and convenient.

A new and excellent kitchen garden has been made at some distance from the house, noteworthy for the fine rows of Peas in full bearing in October, and especially a new variety selected by Mr. Abbott from G. F. Wilson, and named Hallamshire Hero. As grown in comparison with all the newer and more famed varieties in commerce this new Pea held its own most creditably. It was growing about 3½ feet high, the rows being closely covered with long dark green scimetar-shaped pods. It bears some resemblance to Marvel, but surpasses that variety by its darker colour, more sturdy growth, and larger pods. It is of superior quality when cooked, and is the only Pea, so far as I am aware, that has defeated Telegraph in single-dish competition, both the varieties being represented in their best condition.

Although the gardens at Riverdale are not extensive, they are as well worthy of inspection as some establishments of greater size and wider fame.—J. W.

GRAPES WITHOUT FIRE HEAT.

HERE in North Lancashire we are accustomed to have good crops of well-ripened fruit without fire heat. My greenhouse, 26 feet by 15 feet, a lean-to, has eight Vines in front planted in outside borders three years ago. This season I have cut 1 cwt. of good well-coloured Grapes, a portion of which I sent to Covent Garden Market. The salesman appends to the sale note, "A very nice lot."

To say that this season they have been grown entirely without fire heat would be untrue, but I may state that very little coal has been used—not more than 10 to 15 cwt. This may seem very little, but I must add that I sent this spring for a cartload of tanner's spent bark, which can be purchased here for 1s. a load, with which I "bank-up" the fire, and it is wonderful what a saving it effects in the fuel. I have no doubt whatever that I should have had the Grapes ripe without fire heat, only they would have been a little later. I commenced cutting early in September. The varieties I planted are Black Hamburgh, Black Alicante, and Lady Downe's.—J. A.

CARNATIONS AND PICOTEES .- No. 10.

As this season has been so unfavourable in many cases the plants will be late in rooting, and it will be necessary to use pots of the smallest size to root the layers in. Those plants which may not be rooted by the first week in November should be planted closely in a bed under glass. After a week or two, if the weather is mild, most of them will be rooted; they can then be potted off in the ordinary way. Those that may not be rooted can be allowed to remain in the bed until spring and then planted out. Of course it will be necessary to lift the plants carefully so as not to break any of the rootlets.

Now is the time to obtain any varieties that may be required. In all cases try to procure strong plants. Take care not to let the soil in the pots become saturated with water, as, should frost set in or dull weather occur, the plants in many cases will perish, or otherwise they are liable to become cankered. After watering see that the foliage is dry before closing the frames. Old plants may have the lights propped up so that a current of air may pass in amongst the pots. Planting in beds may be continued to the middle of November provided the weather and the ground are suitable for that purpose; after that time planting should be deferred till the latter end of February or early March. All late plants are liable to be disturbed by the frosts. To prevent this place them firmly in the ground and use a few hooked sticks pressed into the soil, allowing the hooks to press on the lower leaves so as to keep them in position. Seedlings will require examining frequently if in the

open to prevent the ravages of slugs, and if the plants are in frames aphides should be looked after. The best insecticide is Gishurst compound, which I use in the proportion of 2 ozs. to a gallon of water. I give the plants infested with aphides a good syringing overhead with the mixture, allowing it to dry on them. In a few days if the insects are all gone the plants may be syringed with clean water.

Having seen most of the best varieties I give my selection which I intend to grow, giving precedence to the new varieties.

William Spoor.—A scarlet bizarre of the finest quality; will in my opinion take a first rank. It is from Dreadnought crossed by Mars. It was raised and is being sent out by Mr. Adams of Swalwell near Gateshead.

Dr. Abercrombie.—Was awarded a first-class certificate at the National Society's Exhibition at South Kensington. A fine

heavy red-edged Picotee, very distinct in colour.

Baroness Burdett Coutts.—A medium-edged purple with fine broad petals. It is a great addition to its class. It also was awarded a first-class certificate. Both the latter varieties

will be sent out by Mr. Charles Turner, Royal Nurseries, Slough. Of older varieties the following list in my estimation con-

tains all or nearly all the varieties worth growing.

Scarlet Bizarres.—Admiral Curzon, Dreadnought, Garibaldi, Lord Napier, Mars, Mercury, Sir Joseph Paxton, and True Briton.

Crimson Bizarres.—Albion's Pride, Captain Stott, Eccentric Jack, Graceless Tom, Jenny Lind, John Simonite, J. D. Hextall, Harland, Lord Milton, Lord Raglan, Marshal Ney, William Murray, Rifleman, Lamplighter, Rev. Geo. Rudrick, Unexpected, and Warrior.

Pink and Purple Bizarres.—Falconbridge, Fanny, James

Taylor, Sarah Payne, and Satisfaction.

Purple Flakes.—Dr. Foster, Earl of Stamford, Juno, James Douglas, Lord Derby, Mayor of Nottingham, Premier, Squire Meynell, and Sporting Lass.

Scarlet Flakes.—Annihilator, Clipper, James Cheetham, Dan Godfrey (Holmes), John Bayley, Illuminator, Mr. Battersby,

and Sportsman.

-Crista-galli, E. S. Dodwell, James Merry-Rose Flakes.weather, John Keet, James Carter, Mary Ann, Maid of Athens, Mrs. Dodwell, Rose of Stapleford, Sibyl, and William Carrick.

PICOTEES.—Red-edged.—Brunette, Clara, Countess of Wilton, Forrester, J. B. Bryant, John Smith, Lord Valentia, Mrs. Small, Mrs. Fuller, Mrs. Bower, Mrs. Dodwell, Morna, Master Norman, Princess of Wales, Rev. F. D. Horner, Thos. William,

William Summers, and Violet Douglas.

Purple-edged.—Alliance, Ann Lord, Alice, Chanticleer,
Cynthia, Ganymede, Her Majesty, Isabella, Jessie, John Delaforce, Mary, Minnie, Mrs. Douglas, Mrs. Niven, Mrs. Summers, Norfolk Beauty, Nymph, Picco, Prima Donna, Silvia, and

Rose and Scarlet-edged.—Charles Adams, Edith Dombrain, Estelle, Ethel, Fanny Helen, Juliana, Lady Louisa, Miss Horner, Miss Lee, Mrs. Love, Mrs. Payne, Miss Wood, Morning Star, Mrs. Adams, Mrs. Allcroft, Mrs. Nicholls, Mrs. Lord, Obadiah, Royal Visit, Teresa, and Victoria.—George Rudd.

MELON CULTURE—THE DRYING-OFF PROCESS.

NOTWITHSTANDING the eighteen years' experience of Mr. Pettigrew in watering Melons until the fruit is ready for cutting, and the successful results of that practice, there will probably be several cultivators who will not accept the soundness of the system detailed on page 301. I am not one of them. It is considerably more than eighteen years since I had the pleasure of securing prizes for Melons at every im-portant London fruit show at which I competed, and the plants were watered carefully, yet regularly, until the very day on which the fruits were cut. At no time were the pits and frames saturated, but sufficient water was given to the roots to keep the plants in a healthy growing state, and the atmosphere always sufficiently moist that, with syringing, kept the foliage quite free from red spider; the leaves in fact were as fresh and green when the fruit was ripe as at any period

of growth.

Nothing is easier than to have excellent second crops of is adopted, and I could never cut fruit of such high quality, as I have often tried, by adopting the drying-off process. A somewhat lessened supply of water than usual when the fruit is about changing will not do harm provided—and this is very important—the foliage is perfectly clean and healthy; but rather than have flaccid foliage and red spider I would, and my notes on Lilies, page 328, and referred to as by no means

always shall, water and syringe until the very time of cutting the fruit. When this system of culture is practised all that is necessary for securing highly flavoured fruit is to sever it from the plants as soon as it has fairly commenced ripening. and place it on a warm dry shelf in the sun for a day or two to finish, and then, the variety being good, it will satisfy most good judges of Melons.

But to achieve success the plan must be carried out intelligently, and heat must be afforded in proportion to the water With much moisture and the low temperature of many dung frames during a cold summer such frequent and continuous watering is not applicable. Neither must the plants be crowded at one time and excessively pruned at another; but the growths should be thin from the first, and daily pinching with the finger and thumb of the laterals not wanted should prevent the necessity of pruning with the knife. Stout good foliage is then produced that will not scorch unless neglected, and that is not likely to be devoured by red spider. No foliage is more liable to injury by rough handling than that of Melons; and if it withers, by whatever cause, before the fruit commences ripening, high quality and superior flavour are out of the question.

It were well if the subject of Melon culture were pondered over during the approaching winter, for it is questionable if, with all the numerous varieties that are ever coming to the front, Melons now, as a rule, are better than they were thirty years ago; but they ought to be, or where is our vaunted progress?—A NORTHERN GARDENER.

NOTES ON USEFUL STOVE FLOWERING PLANTS.

THE Eucharis amazonica grandiflors is one of the most useful of stove plants either for the decoration of rooms or for cutting. It is of easy cultivation, and with a good stock of plants it may be had in flower all the year round. When plants become large and root-bound they should be turned out of their pots, divided and repotted. The soil should consist of very fibry loam broken into pieces about the size of pigeons' eggs, to which should be added a good sprinkling of sheep droppings, equal parts of fresh rough leaf soil, and half-inch charcoal with a dash of sand. When draining our pots we place a large oyster shell over the hole with four or five others round it, on which is placed a mixture of half-inch charcoal and potsherds to the depth of about 2 inches, over this is placed a layer of thin fibry pieces of turf. The plants should not be potted firmly. When the process of potting is finished each leaf should be supported by a stick until the plants are established. lished. Potting may be performed at any season of the year.

They delight in a free use of the syringe at any time, even when at rest. When a few fresh leaves have been made and matured the plants may be moved to a shady corner in a cool vinery, where they should remain for five or six weeks, syringing them twice daily to keep the foliage fresh. At the expiration of the above time if again placed in moist heat they will throw up flower spikes, and weak liquid manure may then be supplied with advantage. When out of flower the plants must remain in moist heat until they have matured a few new leaves, when they may be moved to their cool resting place again and introduced to the heat when required to flower. They are improved by being placed in a shady quarter out of doors in summer during their resting period, for when so treated they produce much finer blooms and in greater numbers. Our plants flower three times a year—July, November, and April; but with a greater number of plants and more space at command we could easily have them in flower every month in We have only Eucharis grandiflora and E. candida in our collection. E. candida only differs from E. grandiflora in the foliage being rounder and smaller, the flower trusses are also more compact.

Plants which may by over-watering or some other misman-agement have become unhealthy should be turned out and the soil shaken from the roots. The plants should then be washed in tepid water, both bulbs and foliage, sprinkling the roots well with silver sand; then if repotted in the compost previously recommended, placed in a moist atmosphere and syringed freely they will soon revive.—H. Elliott.

general or desirable. I should like to hear the opinion of other judges on this point. I was an entomologist before I knew anything of horticulture; and in the accentuated list of British Lepidoptera published by the Entomological Societies of Oxford and Cambridge, I find capital letters used for both species and varieties, and I prefer that mode as the simplest.

In the other "usual" mode the genus is spelt with a capital

In the other "usual" mode the genus is spelt with a capital and the specific name with a small initial letter, except where the word is derived from a proper name; and herein I think lies the element of confusion. Either all the specific names and those of varieties should be spelt with a small initial letter, or all with capitals. The present mode, in my optition, fosters confusion between generic and specific names where spelt with capitals.—ALEXANDER WALLACE, Colohester.

NOTES AND GLEANINGS.

CHRYSANTHEMUMS AROUND LONDON are generally late this year, consequently we find that the Kingston and Surbiton and the Croydon Chrysanthemum Societies have found it necessary to postpone their Shows, the last named from the 13th to the 21st, and the former from the 20th to the 27th of November. That there will be some good blooms cannot be doubted, but we fear from the want of sanshine the wood is not sufficiently ripened for large and neat blooms. The Japanese varieties, which are now as numerous as incurved, will be generally fine, as they can be grown with stronger and more succulent wood without displaying any coarseness of petal, which is a great blemish in an incurved flower. We also find that in places where the plants were potted early and grown luxuriantly through the early part of the summer, that they are later than those that were allowed to remain in 32-size pots until the wood became hard. The early shows around London will, we fear, be found wanting in quantity, while before the last takes place many varieties will be past their best. Those exhibitions occurring from the 18th to the 22nd will be the best.

ASSOCIATION recently held their first meeting of the season for the purpose of reading and discussing practical essays relating to gardening. There was a good attendance, and the first paper was supplied by the Vice-President, Mr. Bardney, on ventilating vineries. The paper was an interesting one. The essayist pointed out the caution that was necessary in admitting air to Vines when subject to very early forcing and in the early stages of their development, while on the other hand abundance of air was requisite in the production of first-class Grapes, without which it was impossible to obtain good colour and finish. Before reading the essay Mr. Bardney pointed out the importance of allowing under gardeners the privilege of attending the Society's meetings. Their case had not been considered by the members of the Association; it was resolved that their admission should be considered at the first general meeting. Several members took an active part in the discussion, and the meeting terminated with a vote of thanks to Mr. Bardney, and to Mr. Faulkner the President of the Association.

— We have a grand old hardy plant in LOBELIA CARDI-NALIS, which produces at this time of the year large panicles of bright scarlet flowers; but there is a great variation in the coloration of the flowers on different plants—some are deep cardinal red. Whatever is the shade of colour they are well worth growing. It has been introduced into this country from the United States since 1629.

—— In the great family Composite the really ornamental species are comparatively few. Here and there, however, in the family we have perfect floral beauties. Take, for instance, SENECIO PULCHER when in full flower, and you would hardly imagine it to be a congener of the common Groundsel. It is of recent introduction, and is a grand addition to our border plants, as it is quite hardy. The large leathery leaves are ornamental, but the flower spikes rise about 2 feet high and are topped with several flowers, which are quite 3 inches across, with the ray florets of a purplish-magenta colour and largely developed, and the central florets yellow and not very conspicuous. We have frequently seen it this year with the foliage attacked by a species of fungus, which is undoubtedly due to the prevalence of wet.

— ANOTHER very handsome little Composite is NEJA GRACILIS, and nearly hardy. The foliage is very slender and Grass-like, of a deep green colour; while the flowers, which

are about an inch scross and produced in grest profusion throughout the summer months, only cease when the frost comes. They are of a bright golden yellow colour, which contrasts beautifully with the foliage. It grows well on a rockery or in a wasma border, and sufficient stock is very easily procured, as the cuttings strike very freely, so as to keep a few plants through the winter sheltered in a cold frame or cool house.

— A VISIT to the MELBOURNE NURSERY at Anerley, which is so ably conducted by Mr. Wills' manager Mr. Bausé, is never devoted of interest. There is always something to There is always something to admire, and were there nothing to be seen but the collections of handsome Dracænas and Crotons a visitor would be amply rewarded. The healthy vigorous appearance of the general stock of plants is highly satisfactory and creditable. Among many other excellent plants the following especially attracted our attention during a recent visit. Curcuma Roscoeana is a pretty ally of the turmeric-yielding C. longa; the flowers are of a yellowish tinge, and are borne on a stout round spike of imbricated scoop-like orange-red bracts. The plant owes its attractiveness to the bracts, which retain their colour long after the flowers have faded. The leaves are broadly lanceolate and gracefully have faded. The leaves are broadly lanceolate and gracefully drooping. Saxifraga Fortunei tricolor resembles in form and habit the well-known S. sarmentosa, but the leaves are prettily variegated with white and pink, the colour being much brighter in the young pendulous plants, the leaves of which are reticulated with a rosy pink. Rivina lævis variegata has variegated foliage, with which the long racemes of scarlet berries contrast most pleasingly. Dioscorea mosaica has broad ovate leaves; the upper surface is dark green marked transversely with small bars of white, while the under surface is of a rich dark purple tint. It is dwarf in habit, and an excellent plant for the stove. Of the numerous Ferns grown there the new Adiantum Bausei at once attracts notice owing to its distinct and elegant appearance; Gymnogramma Pearcei has graceful and exquisitely divided fronds; and Onychium auratum is nearly equally ornamental.

— THE highly attractive BEGONIA MARTIANA is now in excellent condition at Chiswick, bearing numbers of its large bright pink flowers. This fine species is one of the tuberous-rooted section, and a native of Mexico. It succeeds under similar treatment to allied species and varieties, the temperature of an intermediate house being best suited to its requirements. A number of seedling Begonias are also growing in the same house as the above, and among them are several of considerable merit as regards the size, substance, and colours of the flowers.

ONE of the best plants for decorative purposes during winter is the old SALVIA SPLENDENS, the bright scarlet flowers and bracts of which impart quite a gay appearance to a greenhouse or conservatory for a considerable portion of the dull season. It succeeds best and makes finer specimens when planted out during summer than if grown in pots all through the year.

A CORRESPONDENT "H. T." writes that he has had a sad lesson this year in regard to turning CYCLAMENS out of their pots during the summer. He always turned the plants out in the open borders during previous years and with good effect, but this year most of them have lost all their roots from the excessive wet, and several large corms have decayed that bore last year nearly three hundred flowers at one time, and most of the larger corms are much injured.

THAT very peculiar Orchid CYONOCHES WARSCHWICEIL, which Mr. Bull exhibited at the last meeting of the Royal Horticultural Society, is an admirable instance of the phenomenon termed dimorphism. The flowers, as described in our report, are of two very distinct forms; the small one producing pollinia freely, but is apparently defective in the overy, while the large flowers appear to possess perfect overies, the pollinia being either absent or deficient in fertilising properties. It is thus probable that the pollinia of the small form may by insect aid be conveyed to the stigma in the large form, fertilisation being effected as in monoecious plants.

THERE was recently an excellent display of ZOWAL PELARGONIUMS in one of the houses at Chiswick, several of the varieties being of great merit. The most noticeable were the following:—A. F. Barron (George), vigorous habit, flower very large, bright scarlet with small white eye; truss good. Mount Etna has a compact truss of fine scarlet flowers with white eye. John Gibbons, rich glowing scarlet, flowers and truss large. Louis, fine amaranth with a scarlet tinge in the upper petals. Mrs. Wright, excellent pink, neat flower and truss, upper petals.

white at the base. Lizzie Brooks, a superb flower, fine in outline, dark salmon scarlet with white eye; full truss. Lady Sheffield, deep pink, upper petals white at the base; truss large. The last five admirable varieties were raised by Mr. Pearson. The best doubles were Wonderful, good scarlet; Mrs. Trevor Clarke, fine white; Charles Schwind (Pearson) extremely good, bearing enormous trusses of intensely deep scarlet flowers. The effect of such a combination of bright colours and profusion of flowers was remarkably good.

—— At the Bristol Autumn Show of Chrysanthemams, plants, and fruit, upwards of thirty special prizes are offered by supporters of the Society. The silver Knightian medal of the Royal Horticultural Society will be also given for the best grown plant of Chrysanthemum in any class, and the bronze medal for the best three bunches of Grapes on any stand.

— WE find that by the agricultural returns recently published, that ORCHARDS IN GREAT BRITAIN continue to increase in extent, occupying now 175,000 acres as compared with 165,000 acres in 1878. Market gardens have also increased, and in many places the collectors report that the demand for fresh vegetables for the neighbouring towns and the facilities afforded by the railways for bringing produce to London have led many farmers to devote a small portion of their land to vegetables and bush fruits.

— MR. BARDNEY describes ECLIPSE CAULIFLOWER as a very useful variety, and will as it becomes well known commend itself to the majority of growers. It does well in early summer and turns in quickly. It is very dwarf and consequently takes up but little room, and produces splendid beads, which are remarkably white. The last batch of it are now producing fine heads. It contains but few leaves and is not well adapted for protecting itself against frost.

AMONG the numerous foreign fruits which are imported into this country POMEGRANATES appear to be particularly abundant in London at the present time. The Myrtaceous tree, Punica granatum, which produces this rather pleasant fruit, grows on the shores of the Mediterranean Sea, and it is also cultivated in the countries of that region, and from thence our principal supplies are obtained.

— MR. JAMES BURDEN succeeds Mr. Innes as gardener to Sir William Field, Bakenham, Englefield Green, near Staines; and Mr. EDWARD GEORGE, Ballinasloe, has been appointed gardener to T. W. Boord, Esq., M.P., Ockenden, Cuckfield.

THE beds of CHINA ROSES at Gunnersbury Park have been very bright this season owing to the immense number of flowers the plants have borne. The flowers until lately were plentiful, and will continue to expand until the frost checks them. Mr. Roberts finds the buds very useful for bouquets, &c.

— WITH regard to the observations about EARTHING UP POTATOES by "AMATEUR," on page 322, "A SURREY PHYSICIAN." writes as follows:—"Certain rows that were earthed up, and certain others of the same variety not earthed but otherwise similarly treated and planted side by side, were both equally productive; therefore there may be certain circumstances in which, so far as amount of produce is concerned, earthing-up is superfluous, and from the results of his experience it is probable that "AMATEUR" is of a similar opinion. I am glad also to inform "AMATEUR" that the Magnum Bonum Potatoes I have grown are excellent in quality."

—— It is not perhaps generally known how valuable the pretty variegated OPHIOGLOSSUM SPICATUM is for table and room decoration. When the plants are grown in a little heat the foliage assumes a more upright character than is generally seen, and as it then gracefully arches the plants are extremely attractive. The narrow leaves are clearly margined with white, and being smooth and persistent endure the dry air of rooms for a considerable time without being injured. Well-grown plants are equally useful for the margins of greenhouses and conservatories. When flowering the purple Grape Hyacinth-like spike contrasts effectively with the white foliage; but whether in or out of flower the plant is very useful for decorative purposes. As testimony of the increasing popularity of this Ophioglossum we recently observed a batch of plants in Messis. Veitch's nursery, a great portion of which were labelled "sold," Visitors have seen, admired, and purchased them.

—— In the same nursery the PITCHER PLANTS are highly worthy of note and inspection. They have never been finer

than during the past few weeks, and for some time longer they will continue fresh. There are thousands of pitchers depending from the roof, producing an effect altogether unique and probably unequalled. The pitchers throughout are extremely fine, all the best species and varieties being represented. Especially noticeable are some excellent forms of Nepenthes Rafflesiana, the richer and darker N. Hookeriana, with the distinct and valuable hybrids N. hybrida maculata, N. Chelsoni, and several others. Young plants are being raised by thousands to meet the great demand for these novel and beautiful plants which, unlike some others, appear to be always in fashion.

THE ORCHIDS IN AND OUT OF FLOWER cannot be passed in silence. Foremost to arrest attention is the grand Cattleya exoniensis, one of Mr. Dominy's most successful achievements in hybridisation. Although the flowers are not so large as those produced by another plant last year, yet the great number on the specimen and the remarkable combination of chaste and gorgeous colours command general admiration. The beautiful Cattleya labiata is flowering now, also the finely marked and very bright Odontoglossum Londesboroughanum. A fine spike of Saccolabium Blumei majus arrests attention, and several other Orchids contribute to the display. Of the plants not flowering the great batch of Phalænopsids imported only ten weeks ago are not only established, but many of them are producing flower spikes. A number of plants imported at the same time of Angræcum sesquipedale are similarly well established. The plants are in very small pots, or rather tolerably deep saucers, and from these small receptacles fleshy roots are issuing on all sides. The smaller the pots in which Orchids are placed the better the plants appear to thrive. It is wonderful to see the fine healthy growths produced by Dendrobiums in saucers from 3 to 4 inches in diameter. Mr. Dominy has long been impressed in favour of small pots for Orchids, and each year's experience convinces more fully of the soundness of his convictions on the point.

In few gardens of moderate extent is a more select collection of Orchids to be seen than at THE FIRS, SYDENHAM, the residence of C. Dorman, Esq. Mr. Coningsby, the gardener there, is a young man of great intelligence, and takes more than an ordinary interest in his profession, and he is fortunate in possessing an enthusiastic and liberal employer. Four houses are devoted to Orchids, which include most of the best species and varieties, as well as some of considerable rarity and a few importations which have not yet flowered. On the occasion of our visit there was quite a good show of flowers, much better than could be expected at this time of year. The Oncidiums were in fine condition and great variety, the most noticeable being O. varicosum, O. cucullatum, O. ornithorhynchum, the beautiful O. dasytyle, and O. incurvum. Lælias were also flowering freely, and Cattleyas, such as C. Loddigesii and C. exoniensis, were attractive. The remarkable Masdevallia C. exoniensis, were attractive. The remarkable Masdevallia chimera was bearing several flowers with their curiously marked hairy long-tailed sepals, and another distinct species of Masdevallia was flowering-viz., the yellow M. Davisii, a native of Peru. The handsome Zygopetalum maxillare was bright with its pretty flowers, the blue labellums of which are so conspicuous. The attractive Colax jugosus was also bearing several flowers, the sepals being of a creamy tint, petals white striped with purple, and the labellum is white dotted and barred with rich purple. But Orchids are not the only plants that are well represented and well grown at The Firs, for the collection of Crotons is extremely fine, and includes all the newest and best varieties. In the stove is a very fine specimen of Nepenthes Rafflesiana bearing twenty-two large and wellcoloured pitchers.

WINTER BEDDING PLANTS.

A FINER example of the excellent effect that is producible during winter by the tasteful employment of Conifers and small variegated and other shrubs was perhaps never seen than at the last meeting of the Royal Horticultural Society. On that occasion the vestibule at the entrance of the gardens in Exhibition Road was completely filled in the most artistic manner by Messrs. Cherles Lee & Son of the Royal Vineyard Nurseries, Hammersmith, who were worthily awarded a gold medal for the magnitude and excellence of the display. The shrubs, &c., were arranged in various designs, one of which we submit. The plan (fig. 37) combines simplicity with elegance, and is suitable for a large or smell place, according to the size

and number of plants employed. It is engraved on a scale of 1 inch | to the foot. The following shrubs were employed in furnishing the design, which was greatly admired by all visitors :-

Fig. 37.

Cupressus Lawsoniana argentea Cupressus Lawsoniana lutea.

- 1, Edging : Euonymus radicans variegatu riegatus.
 2, Ground : Euonymus microphyllus.
- 3, Euonymus latifolius elegans.
 4, Pyramid : Retinospora ericoides.
- Buxus nana variegata.
 Euonymus aureus elegantissimus.

TOO-MUCH-ALIKE ROSES.—I am now sending out, as suggested by "Oxonian," circulars to Rose exhibitors with the

following queries—1, What Roses do you consider too much alike to be exhibited on the same stand? 2, If so exhibited ought the stand to be disqualified? 3, If not, what amount of bad marks should be given for their presence? As I have said, I fear there will be difficulties, not only because some growers see differences where others do not; but that, even supposing that they are allowed to be similar, it would make a great difference whether they were shown in stands, say of seventy-two, or twelve. In the former case they could hardly bring so much discredit to the stand as in the latter.-D., Deal.

VALLOTA PURPUREA CULTURE.

As many fail in the cultivation of the above beautiful autumn decorative plant, and as a successful grower of it for several years, I will detail the mode of culture adopted. Having a few plants to start with, examine the pots to see if the drainage is perfect or if the plants require a shift into larger pots. If the latter is the case, shake out some of the old soil and repot the plants in pots a size larger, employing a compost of light sandy loam with about one-sixth of welldecomposed cowdung; well drain the pots, pot moderately firm, and place the plants in a cold pit. Keep them close for a few days till they have produced new roots, gradually giving more air until they are removed to a cool greenhouse or vinery for the winter, where all the attention they will require will be to see that they do not become dry nor receive too much

By this mode of treatment they will preserve the foliage green all the winter. As the season advances more water will be required, and it may be applied liberally if the drainage is perfect. A cool vinery is the best place for them, where they may remain until the middle of June; after that they may be placed out of doors on the east side of a wall or hedge or in any partly shaded position, and a slight sprinkling over the foliage in the afternoon is beneficial to them. About the middle of August remove them to a more sunny situation, and supply liquid manure at each alternate watering. I have found a weak solution of guano and soot suit them the best. By the beginning of September they will show signs of flowering. On the blossoms beginning to open they will require placing under cover, as the wet injures the flowers.

The foregoing method is especially adapted for single bulls, but if large masses are desired the same method may be adopted. The most desirable and readiest method to obtain

large masses is to place about nine bulbs in a 10-inch pot. The Vallota is readily propagated by offsets or by seed; the first mode is the quickest.—J. G.

WEASELS DESTROYING THRUSHES AND BLACKBIRDS.

To preserve small fruits from the birds many expedients have been resorted to with only partial success. Scarers answer only for a time; nets, of course, exclude the birds; but so many persons in gardens busy themselves with bush fruits that, though the nets are readily lifted, they are not as carefully readjusted, and any displacement is soon taken advantaged. tage of by the birds.

Our plantations of bush fruit were covered with nets small enough in the mesh to exclude birds, but for reasons above given thrushes and blackbirds found their way inside and were evidently quite at home when weasels appeared upon the scene. Nothing ever made the depredators so anxious of escape from the plantation as one of these smart little animals. It is generally considered that weasels follow their prey by scent, which may hold good when they pursue animals, but that they act by sight I had recent demonstration. A blackbird was turning up the ground with its beak near a batch of Cauliflower plants. I stood watching the bird, when with a bound of about a yard a weasel darted from the shelter of the Cauliflowers and seized it. I afterwards found that the teeth of the weasel had penetrated the brain at the back of the head.

I have seen the weasels dragging mice about to their holes. In a nest of young rats the weasel's entrance is soon followed by a fearful squealing, the whole lot falling quickly beneath the teeth of the weasel. Though a weasel will bring a rabbit to earth with much dexterity and not scruple to attack a hare, yet I have no proof that the animal will attack adult rats. The weasel, however, preys on moles, not infrequently being taken in traps in their runs. Weasels, notwithstanding their remaindestroping and their runs. vermin-destroying propensities, are not safe animals to encourage, as they do not discriminate between the enemies and [the friends of those who tolerate them .- G. ARBEY,

HYPERICUM OBLONGIFOLIUM.

This handsome plant is undoubtedly one of the most attractive and useful species of the large genus Hypericum, and for brightening a shrubbery or mixed border at this season, when all is so dull, it can scarcely be surpassed. The flowers are

large and produced in profusion, the petals possessing great substance, and being of an extremely bright yellow colour. The showy hue of the flowers is further heightened by contrast with the dark green shining leaves. The annexed figure, which represents a specimen we received from Mr. Moorman, conveys a good idea of the appearance of the individual flowers, but the cymes are usually considerably larger, each producing a dozen or more flowers, which resemble at a short distance single yellow Roses.

Fig. 38.—HYPERICUM OBLONGIPOLICM.

The species is a native of North India, where, on the Himalayan, it is found at elevations varying from 6 to 12,000 feet above sea level, and is therefore perfectly hardy in this country. The botanical traveller, Mr. W. Lobb, collected specimens on hills in the neighbourhood of Mufflong and Assam, and by him it was introduced to Messrs. Veitch & Sons' nurseries at Exeter and Chelsea, and it has for some time been flowering freely in the Coombe Wood Nurseries of that firm, producing a most cheerful effect amidst the surrounding greenery.

EUPATORIUM ODORATUM.

the more valuable. Considering its easy culture and other good qualities it is a little surprising that it is not more extensively grown. Plants after flowering should be pruned and placed in a vinery to start them into growth, in order to obtain cuttings, which succeed with the same treatment given to Fuchsias in their earlier stages of culture. After the cuttings are well rooted they should be placed singly in 3-inch pots, employing good loam and sand. They must be pinched back frequently to prevent their becoming leggy. The next shift may be into 6-inch pots, which will be large enough to flower them in the first year. They should be grown in a temperature of 55° till the middle of May, and afterwards gradually hardened off, and ONE of the many useful winter and spring-flowering plants | when all danger of frost is past they should be plunged out of is the above. Coming in as it does at a time when flowers, and especially white flowers, are in great demand renders it | October the plants may be taken under cover, and by the end of November they will commence flowering. Old plants come into flower the earliest, so that a succession of flowers may be had till April or May. It is a useful plant to cut from, the flowers lasting a long time after being cut, and for the decoration of halls and rooms the plants stand well. Its sweet perfume, somewhat resembling that of honey, and its beautiful dark green foliage adds an additional charm to the plants.

—JAMES SKYEME, Ellergreen, Kendal.

THE TWEED VINEYARDS, CLOVENFORDS.

In consideration of the importance of Grape-growing, and also the fact that there is no part of a gardener's skill that is more valued, a few notes on the above Vineyards, the property of Messrs. W. Thomson & Sons, may be acceptable to the readers of the Journal. Grape-growing privately and commercially are two entirely different matters. It must be satisfactory to know that Mr. Thomson has been successful in the work that he was so admittedly competent to undertake. The commercial prosperity of the Vineyards may be certified by the fact that the demand for the produce is not only continental, but some of the principal Courts of Europe are supplied with fruit by Mr. Thomson.

Those Vineyards are upwards of 3 acres in extent, the whole of which are nearly covered with glass. The houses are principally span-roofed; most of them are 200 feet long by 24 broad. They are all well supplied with hot-water pipes, which are evenly distributed over the surface. Mr. Thomson finds it absolutely necessary to provide plenty of heating surface especially for span-roofs, and he finds the plan economical in the end, for a considerably less quantity of fuel is necessary than where the piping is limited. The boilers are of the saddle and cruciform shape, by Meiklejohn, and perform their work satis-

factorily.

The first house we entered contained all Lady Downe's, bearing fine market bunches of from 2 to 3 lbs. weight, evenly distributed over the house, large in berry and just finishing colouring. Another house at right angles to the one indicated, of the same dimensions, contained excellent examples of Black Hamburgh and Duke of Buccleuch; the latter being in excellent condition, perfectly free from spot, and well finished. Mr. Thomson finds it for market purposes an excellent summer Grape. As a predecessor to the Muscat of Alexandria it is a great favourite. He also emphatically declares that ordinary Hamburgh treatment is sufficient to insure success, and all nostrums such as grafting it on other stocks he does not find at all necessary.

Another span-roofed house contained magnificent bunches, principally of Black Alicante and Gros Colman; this latter was very fine, its large round berries so well developed reminded us of Plums, and some of the leaves measured 16 inches across. This variety, Mr. Thomson finds, does best on the Muscat of Alexandria stock, and is invaluable for market purposes; for the month of January he much prefers it to Barbarossa. The Vines are generally planted 6 feet apart, and two rods trained from every Vine. The practice of stopping to one or two eyes above each bunch is not rigidly followed, neither are they allowed to ramble at considerable distances, A happy mean is evidently followed with excellent results.

Mr. Thomson still follows the practice of watering at the periods of starting the Vines, again when the Grapes commence swelling, and towards the end of the season, each time giving very copious supplies, and the borders inside and out are mulched 3 or 4 inches thick with fresh cowdung. Also every year the inside and outside borders receive alternately a dressing of quicklime, which is found of great value. The glass used is 21-ox, the panes being about 15 inches broad and 2 feet long. It may not be uninteresting to state that in four

of the vineries 35 tons of glass were used.

We passed through several other houses of the same size as those described containing nearly the same varieties, one Muscat house being exceptionally fine. Muscats in their second year had made very fine rods, and were bearing about three bunches to each rod. This being for a late house contained an extra quantity of piping, about 2000 feet, or nearly half a mile. Another contained Muscats and the Duke. A number of varieties Mr. Thomson does not grow, but only such as he finds to pay for marketing. Early Grapes are not now attempted, neither are Pines nor Vines for planting, Grapes being the speciality.

In concluding our remarks we must not omit to mention the splendid collection of Orchids that are in perfect health.

They are not grown for commercial purposes, but more for the love the proprietors possess for them. In the East India house we noted Vanda tricolor and V. suavis very good, with leaves to the pot's edge; also Lælia purpurata and L. anceps. Cypripediums are also well represented by such as Hookeri, Harrisonianum, and villosum. Cattleyas were also numerous.

A number of small span-roofed houses for the forcing of

A number of small span-roofed houses for the forcing of flowers are also worthy of mention. Nothing but the best of everything is grown for market purposes. In one of the store we observed Dipladenia boliviensis was growing extensively as a stove climber, the flowers of which are invaluable for wreaths or bouquets. Stephanotises were also rampant, and Gardenias planted out were yielding choice flowers. In the cooler frames the white Wallflower Stock was predominant, being found so useful for the winter. Great quantities of Pelargoniums are grown at all times of the year. For winter blooming Mr. Thomson speaks highly of Master Christine, Vesuvius, and Wonderful; and amongst double pinks, Madame Thibaut is a deserved favourite.

The neighbourhood is also interesting to the visitor, where he can at leisure inspect some of the magnificent rugged Scotch scenery, wild and majestic as it is, the stupendous hills rising in some instances almost perpendicularly from the foot of the river Tweed, and sinking as suddenly into deep abysses; and amongst the mountain herbage the sheep are scarcely visible, while here and there are irregular plantations of Pines which add diversity to the scene. Ashby Hall, the seat of the late General Sir James Russell, where Sir Walter Scott wrote some of his most thrilling novels, Melrose Abbey, Abbotaford and other places of historic interest abound in the neighbourhood. No genuine gardener who visits Clovenfords can fail to receive a courteous and genial welcome from the proprietor and his sons, and he will leave the place as I did with "food for reflection."—B. COWAN.

THE WEATHER.

A DISTINGUISHED American once resident in England was accustomed to remark, in the pleasant way in which relations talk of each other, "that the one thing the English did not boast about was the one thing they had to boast of, and that was the weather." Also King Charles II., of larger climatic experiences than any other of our monarchs, used to say that there were more days in England in which you could be out in the open air all day than in any other country. Such a season as we have been passing through might have altered the opinion of either gentleman. The singular thing is the way in which America is supposed to have been affecting us, although I believe there is no case on record of a cyclone, as storms are now called, ever having been proved to have crossed the Atlantic. How the New York Herald makes out those mysterious warnings which, cabled across, come true so often, is certainly a great wonder, and the secret so far has been excelently well kept. Some kind of idea may be obtained from general broad principles.

general broad principles.

Our normal state if they are not interfered with, which they very often are, is to have westerly winds. A westerly wind meeting with some check causing a whirl in it from left to right, of which the centre is depressed, is called now-a-days a cyclone. These cyclones have one special breeding place in the Atlantic, that is on the banks of Newfoundland. There the warm Gulf Stream meets the cold Arctic waters; there the moist west wind is run into by the north wind from off the east coast of Greenland, and the frequent result is very excitable weather. Now the banks of Newfoundland are considerably nearer to New York than they are to England, and the logs of ships arriving from there at New York are very suggestive as to the kind of weather which is taking its rise there. Hence (it is put forward by Mr. J. K. Laughton in a particularly interesting article on this subject in the August France)—those forecasting ideas may possibly be obtained by the New York Herald people, which they formulate into those intimations of depressing disturbances or disturbing depressions which for so many months now have been affecting us in either way.

An anticyclone is happily in every respect the exact opposite

An anticyclone is happily in every respect the exact opposite of a cyclone. It remains where it forms; its centre is elevated instead of being depressed; it has generally calm light winds from the east rather than west; it brings with it almost invariably settled weather. It is therefore a very welcome notice in our daily forecast, and it will have been observed that of late it has not been quite such a stranger.

I called attention in February to the disturbing statement

which had come to us from the western land, whence came telegrams of depressions month after month with such fatal accuracy. I mentioned the American statement respecting the sinister effects of a simultaneous perihelia of the four giant planets. Since the cessation of those far too accurate cable warnings I have met with another American statement. This is to the effect that the four giant planets will not be all at their closest to the sun all together, and that if they were it would not produce any effect. The dates of perihelion passages are now exactly given:—Jupiter 1880, Neptune 1881, Uranus 1882, and Saturn 1883; also about May 25th, 1881, Mars will be at its nearest point to the sun.

Professor Colbert now states, in opposition to Dr. Knapp, who first started the alarmist theory: "We are not warranted in believing that the combined perihelion passage of the four principal planets will work more than from 3 to 7 per cent. more harm to the human race than is caused by Jupiter once in every twelve years or a little less, when he makes his peri-helion passage alone." This conclusion he founds upon some elaborate figuring hardly fitted for our Journal. But the two opinions and statements are worthy of notice and knowledge.

Mr. Pope would remark on it-

"Who shall decide when doctors disagree, And learned casulate doubt like you and me?"

--A. C.

NOTES ON VILLA AND SUBURBAN GARDENING.

RLOWER GARDEN AND SHRUBBERIES.—Continue to keep beds, borders, and grass plots neat and fresh by the timely removal of leaves and wormcasts. Where large trees abound the leaves are falling fast, and will cause gardens to bear a very untidy appearance for some time to come. Collect the leaves as they fall, and stack them in a heap to mix with manure in the early spring. Sweep lawns frequently and roll them occasionally. Where alterations of any kind are contemplated they should be commenced at once. It often happens that in amateurs' gardens of recent formation many alterations require to be made annually. Inequalities are noticeable on newly laid lawns, or the shrube in the borders have grown so rapidly as to become crowded and thereby injure each other. The present is a good time for giving attention to these points, which if neglected will soon give a desolate appearance to any garden. Lewns should be smooth, and every plant in the borders should stand free and boldly from each other. Drains that have become defective should be taken up and relaid. All these matters form suitable work for the present time.

ROSES.—Planting and transplanting will now be the chief employment, but it is necessary to complete alterations as early as possible; and if a good dressing of partly decayed manure can be spread over the surface, the rains will not only wash the nutriment down to the roots but the drier portion forms a protection to the roots during severe weather. It is unnecessary to give a selection of varieties suitable for suburban gardens, they are so often given in the pages of the Journal, for most of the varieties selected for exhibition are also suitable for a home display. The Briar stock is the best to plant on heavy retentive soils, while the Manetti will flourish best on lighter soils. Do not plant Briars any deeper than they have been growing before, but plant the Manettis deep enough for the union between the bud and stock to be placed undermeath the soil. Cuttings of Roses taken off and inserted in a warm border now will strike readily, but the operation must not be delayed.

KITCHEN GABDEN.—Asparagus stems are now turning yellow and should be removed, and a winter dressing about 3 inches in depth of well-decayed menure spread over the surface. If the alleys contain plenty of soil a slight covering may be spread over the dung, but it is not a good practice to take them out too deep, or the roots from the plants growing nearest the sides become exposed. If it is intended to make new beds no better time than the present can be chosen for trenching the ground. It will then be exposed to the influence of the atmosphere during winter, and will exposed to the innuence of the atmosphere during winter, and will be in fine condition next April. Cucumbers in frames are now over, and it will be well to clear the haulm away, take the surface, and place a number of Lettuce and Endive plants lifted with good balls within for protection. Clear away all healm of Scarlet Runners, de.; place the stakes in bundles either for burning as firewood or to serve as stakes next year.

Chrysanthemums opening their flower buds should have a plential arrayler of unterstand comful attention by giving and

bright days ventilate freely. Keep the greenhouse cool, dry, and clean, and let any watering be done in the morning. Attend to Calceolarias, Cinerarias, and Primulas, and keep green fly in check. The night temperature of greenhouses where Azaleas, Camellias, &c., are kept should be about 40°, but warmer structures for stove plants about 60°, allowing it to rise higher by day with sun heat. Clerodendrons, Bougainvilleas, and Allamandas intended as specimen plants should be allowed to rest in the warmest corner of the stove. Hyacinths and other balbs may still be potted, but the sooner such work is done the better, as the bulbs will shortly commence growing.

WORK FOR THE WEEK.

COMPLETE the earthing-up of Celery, but the late crops which are yet growing freely may have the final earthing deferred for a time. Late Turnips should be examined, and those fit for use may be taken up and stored in moist sand. On dry days take up Cauliflowers with well-formed heads, and place them in a pit or other sheltered situation. Veitch's Autumn Giant is the best variety for late use, as it is not so liable to suffer from damp as others, whilst the quality is excellent. Taking up root crops such as Carrots, Beet, Salsafy, &c., should be proceeded with and completed as soon as possible. Paranips also may be taken up, but if the ground they occupy is not required for other purposes they may remain some time longer. Lettuces and Endive in frames, &c., should have abundance of air on all favourable occaframes, &c., should have abundance of air on all favourable occasions. Dusting with quicklime, dry wood ashes, or soot will occasionally be necessary for young Lettuce and Cauliflower plants to protect them from the ravages of slugs. When the haulm of Asparagus is yellow it should be removed, and give the beds a sprinkling of salt, and dress them with well-decomposed dung, afterwards surfacing with soil from the alleys. The decayed leaves of Scakale may also be removed and the crowns covered with a little sawdust, spent tan, or sahes. When Seakale is grown extensively for fercing it is better to take up the roots is grown extensively for forcing it is better to take up the roots so soon as the foliage is matured and lay them in a sheltered position. Peas may now be sown in any warm sheltered situation; First and Best is still one of the finest early Peas, and William I. is also good. For sowing at the base of walls with a southern aspect Extra Early Premium, Blue Peter, and Little Gem are very productive and early varieties. Broad Beans may also be sown in a sheltered situation; Early Maragan is the hardiest, but that is its only recommendation, Early Long-pod being much superior, and Beck's Gem from its dwarfness is suitable for sowing on warm borders to afford an early supply.

For sowing on warm borders to afford an early supply.

Forcing Department.—A few roots of Rhubarb should now be placed in the Mushroom house or other house having a temperature of 55° to 65°, placing them in rich moist soil, but not watering until growth commences, and then with tepid liquid manure; Johnstone's St. Martin is the best for forcing. Forcing Seakale may also be commenced, selecting strong roots with bold well-ripened crowns, placing them in moist rich soil, and not watering ripened crowns, placing them in moist rich soil, and not watering until growth commences. It is necessary that the Seakale be placed in the Mushroom or other warm house, and means must be employed to exclude light to ensure the blanching of the growth. An early bed of Asparagus may be planted, there being nothing better for the purpose than a bed of dung and leaves placed in a pit heated by hot-water pipes so as to admit of air being given. Unless the demand be urgent very early forcing of this esteemed vegetable is not advisable. Dwarf Kidney Beans must be kept near to the glass and well supplied with water and must be kept near to the glass and well supplied with water and liquid manure after they come into flower. To grew these Beans well in winter they require as the days become shorter more heat than in early autumn and spring; 60° to 65° at night is not too much, and 70° to 75° by day. Make successional sowings as required

to ensure a continuous supply.

PRUIT HOUSES.

Figs.—Trees in pots intended for early forcing should, if they have been placed in the open air, be taken under cover to protect them from the cold autumn rains. It is presumed that the trees have been top-dressed, repotted, or had the drainage rectified, as advised in a former calendar. The trees should be placed in a rather dry well-ventilated house. Any thinning or shortening crowded attenuated growths should be attended to, and the trees crowded attenuated growths should be attenued to, and the trees dressed with an insecticide—8 ors. of nicotine scap in a gallon of water is suitable, or 1 lb. of soft scap in a gallon of water, adding flowers of sulphur; apply the dressing with a brush. A dish of forced Figs early in the season is new considered a necessity in large establishments, and is not by any means difficult to obtain. A light well-ventilated house is necessary, having pits containing fermenting materials to afford bottom heat to stimulate the roots and afford a constant supply of nutritive matter. The Fig requires abundance of liquid manure when growing, the trees being most prolific under limited root space. One of the great advantages of Fig culture in pots is the number of varieties that may be grown in a house of moderate dimensions, and which if forced grown in a house of moderate dimensions, and which it forced early come in at a time when the dessert is not over-varied. Brown Turkey and White Marseilles are excellent in every respect, they, with the following, being well suited for forcing and pot-culture:—Osborn's Prolific, Early Violet, Black Ischia, Brown Ischia, Black Provence (Black Marseilles), Violette de Bordeaux, Negro Largo, Angelique, White Ischia, Col di Signora Bianca, and Boyal Vineyard.

Peaches and Nectories.—Admit all the air practicable to trees in houses, indeed with portable roofs the lights way with advantage.

houses; indeed, with portable roofs the lights may with advantage be removed so as to admit the autumn rains, and more thoroughly to induce rest, besides cleansing and invigorating the trees.

exposure, though not so necessary with midseason and late houses, is of great advantage to the trees. Root-pruning and lifting in the is of great advantage to the trees. Root-pruning and lifting in the succession and late houses should be proceeded with as the wood becomes ripened. As a rule all trees may safely be commenced with as soon as the leaves part freely from the shoots. Young trees are more difficult to deal with than those that are aged, but to check their luxuriance a trench may be taken out at such a distance from the stem as will shorten the strongest roots. This will also be an advisable plan to pursue with trees in late un-heated houses. The trenches need not be filled in again for a fortnight, which will cause the trees to fill the space undisturbed with fresh rootlets. At the same time remove all growths not required for the extension of the trees. The trees in the early house from which ripe fruit is to be gathered in May must with-out further delay have the final pruning, and dress the old and young wood with an insecticide, replacing the lights, painting the woodwork and trellis if necessary, and tying the trees to the trellis, covering the outside border with some protective material so as to prevent the soil from being too much saturated and cooled by the autumn rains. Admit air freely day and night, as a close atmosphere when the trees should have rest is more provocative of the buds dropping than is considered to be the case. From the fall of the leaf to closing the house the rest should be

as complete as possible.

Cucumbers.—The autumn-fruiting plants are now in good bearing.

Maintain a night temperature of 70° to 75° by day, and 80° to 85° from sun heat. Admit a little air at the upper part of the house on every favourable occasion, but not sufficient to lower the temperature. In the case of bright cold days it is better to partially turn off the heat for a few hours than to ventilate too freely. Sudden fluctuations of temperature should be avoided, and the water should be of the same temperature as the house before applying it to the roots. Syringe the foliage only during bright afternoons, but keep the evaporation troughs filled. Damp the paths, walls, &c., morning and afternoon in warm clear weather. Allow the winter-fruiting plants to advance well up the trellis before stopping, and afterwards train the shoots to the right and left of the stem Remove all tendrils and male blossoms as fast as they appear, adding a little fresh soil, which has been previously warmed,

as fast as the roots cover the surface of the bed Pines.—Continue the course of treatment advised in our last calendar. Examine the fruiting plants occasionally and remove all superfluous suckers, retaining only the best one on each plant. In the case of successional plants remove all suckers that appear before the fruit is visible, excepting, of course, it is desired to increase the stock. In most establishments the young stock is grown in fermenting beds until the plants are in a proper state for fruiting, which is very suitable; but fruiting plants are more satisfactorily treated by having hot-water pipes to supply the needful heat to the roots. In the case of fermenting beds it is usual to replenish or make new beds as may be necessary at this time of year. Tan is by far the best material, as it is more durable than one others. than any other, and the best substitute for it is Oak or Beech leaves, which should be collected in a dry state, and when the bed is made it should be firmly pressed; but tan, on the other hand, should be placed lightly together.

PLANT HOUSES.

Orchids.—Aërides, Vandas, Saccolabiums, Phalænopses, and similar plants will be in a state of partial rest, and will only require sufficient water at the roots to keep the moss damp, but if allowed to become too dry the bottom leaves shrivel and fall. Premature growth should be prevented by keeping the atmosphere of the house comparatively cool and dry. A little water should be poured on the paths in the morning. Air should be admitted through the bottom ventilators, but very little will be required. Most Dendrobiums will now be at rest; they require to be kept Most Dendrobiums will now be at rest; they require to be kept coel and dry. Cattleyas require a long season of rest to enable them to make vigorous growth in the spring, and should be kept rather dry, the pseudobulbs not being allowed to shrivel; but very little water is now required to keep them plump. Cattleya Warscewiczii will make a grand display of flower during the winter months. A light position should be given and drip avoided, otherwise the buds decay. Cypripediums do not require any rest; water must be given them liberally at all seasons. Calanthe vestita coming into flower should have very moderate supplies of water, and should be kept in the driest part of the house fully exposed to light. Lycaste Skinneri though a waterloving plant requires less at this season; but the roots must not be allowed to become too dry or the pseudobulbs shrivel, and unless allowed to become too dry or the pseudobulbs shrivel, and unless they are well elevated so as to allow the water to pass away freely from their base the flower buds decay when they are about an inch in length. Many Odontoglossums and Masdevallias still grewing freely must be kept moist at the roots; but although these plants require plenty of water care must be taken at this these plants require pienty or water care must be taken at this season not to have a saturated atmosphere. O. newium and O. Phalsenopsis require a little more warmth at this season, and should be placed at the warmest end, or in the Mexican house.

Store.—Gardenias that are well set with flower buds may be placed in a higher temperature—70° to 75°, when they will come into flower in a few weeks and be very acceptable. Tabernæ-

montana coronaria flore-pleno is even more beautiful than a Gardenia, and may be similarly treated. Eucharises having completed their growth and rested for about six weeks should be returned to heat, and if placed in bottom heat of 85° to 90° they returned to heat, and if placed in bottom heat of 35° to 90° they will throw up the scapes more freely. All winter-flowering plants should have light positions and be near to the glass, supplying any plants in small pots with liquid manure once or twice a week. During the winter season there is a great demand for plants of moderate size for decorative purposes, and plants with finely coloured leaves are useful now. Crotons, Dracenas, Acalyphas, &c., are very distinct and may be had in character in pots of moderate are very distinct and may be had in character in pots of moderate size, or in stately specimens; and many small-growing, fine-leaved plants, such as Bertolonias, Fittonias, Peperomias, Sonerilas, and Tillandsias, which occupy little space, and are very effective for margins, &c., easily propagated and grown. Be somewhat sparing of moisture in this structure, but maintain a moderate degree of humidity where there are growing plants, with free circulation of air when the external air is mild, and a temperature of 60° to 65° at wight and 50° to 75° had a will be sufficient for most street. at night and 70° to 75° by day will be sufficient for most stove plants at this season. Gradually withhold water from such plants as Allamandas, keeping them in the coolest, driest and most airy part of the house, affording evergreens at rest no more water than is sufficient to maintain the foliage in good condition.

Greenhouse.—Herbaceous Calceolarias will now require potting

Greenhouse.—Herbaceous Calceolarias will now require potting off singly; 3-inch pots will be large enough for the first shift, employing turfy loam well reduced with a fourth part of leaf soil and well-decayed manure, with about a sixth of sand. If there is any trace of aphides dip the plants in tobacco water prior to potting. Place them in a pit, and if kept cool (frost only excluded) and moist all the better. Move the second batch of Cinerarias into the pots in which they will flower, and keep them near to the glass. Chrysanthemums should be protected from frost, but there must not be any attempt at keeping them close; they cannot have too much air and light, but frost must be excluded.

TO CORRESPONDENTS.

* All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

SEEDLING GLOXINIAS (E. Molyneux).—The varieties are excellent, the flowers being large, of great substance, and the colours varied. The dark flowers are very rich, and the lights clear and attractively marked.

REMOVING TREES (L. L.).—Although the young trees have not shed their leaves they will move safely if you cut off all the foliage and keep the roots moist during transit. It is better for the foliage to wither in a natural manner, but as you cannot wait for that you may adopt the course suggested rather than "leave the trees behind." By cutting off the leaves now they are so nearly matured you will not seriously, if at all, weaken the trees, and you will remove the evaporating surfaces and prevent the wood shrivelling.

VINES FOR MIXED HOUSE (J. M. A.).—Your house will accommodate seven Vines. If you want as many varieties you may plant Black Hamburgh, Foster's Seedling, Madresfield Court, Alicante, Muscat of Alexandria, Lady Downe's, and Trebbiano—that is, assuming the house is sufficiently heated for all those varieties. A more useful mode of coupying the house would be to plant two Vines of Muscat of Alexandria at the warmest end, three of Black Hamburgh, one of Foster's Seedling, and one of Madresfield Court. Three good Peaches for your house are Rivers Early York, Grosse Mignonne, and Barrington, which ripen in succession. If you desire a Nectarine you may plant Lord Napier. Very few plants succeed on the back wall of a vinery when the roof is covered with foliage. Camellias will do so, but they grow rather slowly, and should not be planted until the wall is partially shaded with the Vines. Hoya carnosa grows and flowers well in the shade.

VINES IN POTS (Park Hill).—It is not necessary to repot the Vines now

VINES IN POTS (Park Hill).—It is not necessary to repot the Vines now growing in 12-inch pots, but previously to placing them in heat you may remove a portion of the old soil carefully, not seriously disturbing the roots, and apply some fresh and richer compost, pressing it firmly; and as the Vines advance in growth you may further mulch with rich manure. See that the drainage is right. Some good growers plunge the pots in leaves

when starting the Vines, bending the canes over the pots' sides and pegging them down into rich turfy soil and manure previously to training them up the rafters, and so obtain a "double set" of roots. We have seen excellent crops of Grapes follow that mode of treatment.

WINTERING COLEUSES (Idem).—Plants when much pruned at this late period of the year not unfrequently damp considerably—that is, the branches below the point of severance commence decaying, especially if the temperature is rather low. If you have a warm light stove in which you can winter the plants you may prune them moderately, otherwise you had better let them alone.

PRINULAS UNHEALTHY (Subscriber, Chepsicus).—The old plants to which you allude were to a considerable extent exhausted by flowering and, perhaps, seeding in the spring, hence the yellowness of their foliage now. If the roots are active you may improve the colour of the leaves by occasionally watering the plants with rather weak and quite clear soot water, and placing them in a house where the night temperature is not lower than 45°.

TACSONIA NOT PLOWERING (*Idem*).—The Tacsonia does not flower because its growths, being shaded by the Vines, are not matured. Your only chance of obtaining flowers is to train the growths thinly during the growing season so that the foliage can have all the light possible, and even then you cannot expect the plant to flower freely, as the position is unsuitable.

cannot expect the plant to flower freely, as the position is unsuitable.

RENEWING VINE BORDER (Old Sub).—If you remove the soil as you propose the Grapes hanging on the Vines will shrivel. If the Grapes are quite tipe and you have a dry and moderately cool room at your disposal you can cut the fruit, securing a portion of the laterals for insertion in bottles of water —ordinary wine bottles will do; and the bunches may be preserved as well suspended in the room as hanging on the Vines. They should be cut when the foliage is changing, removing it from the laterals when they are placed in bottles. The border can then be renewed at once as you propose, placing the roots within 6 inches of the surface. If you cannot bottle the Grapes you must not renew the borders until the crop is cut in the ordinary manner. In addition to the bones add some wood ashes to the compost, but not much manure unless the loam is poor, as manure is best applied as surface dressings. Without such applications to inside borders, and watering them sufficiently yet judiciously, the roots will pass into the outside borders. You are quite right in endeavouring to encourage roots in the inside of the house, but make the outside border good also.

POTTING FRUIT TREES ([dem).—If you can preserve the foliage fresh by

make the outside border good also.

POTTING FRUIT TREES (Idem).—If you can preserve the foliage fresh by placing the trees in a shady position for a time, syringing occasionally if the weather is dry, you may pot them now, and root-action will commence at once; but if you cannot keep the foliage fresh you will gain nothing, but rather lose by digging up and potting the trees until most of the leaves have fallen. Your safest plan probably will be to let the trees remain where they are until the leaves change and commence falling rather freely when the trees are shaken. By removing trees prematurely the wood not unfrequently shrivels, and shrivelling is not maturation.

GARDENER'S SALARY (Horace).—You do not say that you provide a house in addition to the wages you give to the gardener, whom you state is a very good one and suits you so well. A really skilled, intelligent, and trustworthy gardener should have a house, or an equivalent, in addition to the wages you name, which do not exceed the earnings of many mechanics' labourers in London and other towns. There is no "usual rate" of gardeners' wages; some employers obtain the services of men at the lowest possible cost, others are disposed to make able and worthy men really comfortable, and the latter class—to which you belong—are usually the best served.

WINTERING BEDDING PELARGONIUMS (A Constant Subscriber, Liverpool)—You cannot winter the young plants recently struck from cuttings in a spare room unless they are placed close to a light window and the room is frost-proof during severe weather, but you may perhaps succeed in preserving a portion of the old plants. Remove all the leaves from them now, except those that do not much exceed an inch in diameter at the ends of the shoots. Keep the soil in the pots perceptibly moist, so as to preserve the roots fresh, yet be careful not to over-water. When you do apply water give sufficient to penetrate the entire mass of soil; nothing is more fatal to success than mere sprinklings, rendering the surface of the soil moist while it is as day as dust below. A warm cellar is very unsuitable for plants that have been cut down, as it promotes fresh growth too soon, and unless this fresh growth can have light it inevitably perishes. A dry frame placed in a very shelterd position would preserve the young plants until the approach of severe frost, keeping them dry, then remove them to your greenhouse if completed, or to the windows of your dwelling. Plants in leaf must have light; those having no leaves may be kept in a semi-dark place for a time until they commence growing. You may remove the leaves from old plants taken from the beds, but not from plants recently struck from cuttings.

RUSHES FOR SECURING ROSE BUDS (T. B., Barkly Hall).—"D., Deal," states that a letter addressed to M. J. Margottin fils., Bourg-la-Reine, Paris, would probably enable you to procure some of the rushes to which you refer, as M. Margottin offered to obtain some for a gentleman who was visiting the nurseries with "D., Deal."

nurseries with "D., Deal."

STEPHANOTIS LEAVES FALLING (Cranfordian).—It is not unusual for some of the leaves to turn yellow and drop off at this period of the year, but the defoliation of your plant is excessive. It has received a check of some kind, and as the temperature is right the evil must be sought at the roots. Probably the soil at the bottom of the box over the hot-water pipes has been allowed to become dry at some time or other. All you can do now is to give sufficient water to keep the roots healthy during the winter, and in the spring remove a portion of the old soil and apply some fresh compost—turfy loam and peat with charcoal freely intermixed—to induce fresh and healthy root-action; then by increased temperature and syringing the plant may push fresh growths. The more upright these are trained the more rapidly they grow; but a healthy plant usually grows freely enough when trained, across the rafters.

DESTROYING AMERICAN BLIGHT (C. H. P.)—Paraffin oil is efficacions.

DESTROYING AMERICAN BLIGHT (C. H. P.).—Parafin oil is efficacious, and if judiciously applied is not injurious to the trees. It should be applied with a brush to the parts affected, taking care that it does not run down the stem to the roots, and is not allowed to touch the foliage and young shoots. If employed over the foliage a wine-glassful to four gallons of water is sufficient.

SOWING CYCLAMEN SEED (Curate).—Provided you can command heat, say a temperature of 55° to 65° by artificial means, the seed may be sown now, placing the pots or pans near to the glass. If you have only the convenience of a greenhouse do not sow the seed until February or early March,

placing the pans in a hotbed, and grow the young plants in a frame during the summer.

RAISING SOLANUMS FROM SEED (*Idem*).—Sow the seed early in March, placing the pans in a hotbed, and when the plants are large enough to handle pot them off singly in 3-inch pots, returning them to the hotbed until established, when they may be gradually hardened-off and grown-on during the summer in a cold frame, shifting the plants into larger pots as they require it. In September they may be removed to the greenhouse, assigning them light airy positions near the glass. Plants from seed do not produce berries well the first season, but improve with age. We cannot advise on the other question.

advise on the other question.

DRESSING A LAWN WITH GAS LIME (B. T. J.).—Although you state the quantity of soil to be mixed with the gas lime, you give no data as to the quantity you propose to apply to a given area. Of a compost formed of "one part gas lime to three parts of soil," eighty bushels will be sufficient for one acre if it is thoroughly incorporated with the soil, and as evenly distributed over the surface as possible. It should be applied now, as the moss is most active; or if you value the appearance of the lawn during the winter, as the lime will in all probability render the grass brown more or less, the dressing may be deferred until February or early March. A stronger application of gas lime would be more certain of killing the moss, but would have a decidedly injurious effect on the grass and is not advisable. The light dressing above named—viz., thenty bushels of the lime per acre, may be applied to the kitchen garden now and dug in, but it must be kept from fruit trees. Gas lime is a good application to ground long under crops, as it destroys predatory vermin, and is one of the best preventives of "club root." It should be used in its fresh state, and dug-in in the autumn, as after long exposure to the action of air and water the hydrosulphuret of lime is converted into sulphate of lime or gypsum, which in itself is a valuable manure for grass; but the value of the gas lime as a destroyer of insect life is dependant on the sulphuret of lime, hence the necessity of its application in small quantity so as not to injuriously affect vegetation as an overdose would do for a lengthened period.

AMERICAN BLIGHT (Mr. Fenion).—The best treatment of Apple trees attacked by American blight is to apply paraffin to the parts affected, not touching the smooth clean portion of the bark with the solution. We cannot tell you about the incubators.

PEARS AND APPLES FOR SOUTH-EAST ASPECT (C. L.).—Pears: Jargonelle, Williams' Bon Chrêtien, Beurré d'Amanlis, Louise Bonne of Jersey, Marie Louise, Durondeau, Beurré Diel, and Glou Morçeau. Dessert Apples: Worcester Pearmain, King of the Pippins, Cox's Orange Pippin, Welford Park Nonesuch, Gravenstein, Reinette de Canada, Dutch Mignonne, and Sturmer Pippin.

PERENNIALS FOR EXPOSED SITUATIONS (A. R.).—Achillea aurea, Ajuga orientalis, Allium ciliatum, A. grandifiorum, A. Moly, Alyssum saxatile compactum, Anemone apennina, A. japonica alba, Aquilegia chrysantha, A. vulgaris alba, Arabis albida, Armeria maritima alba, Aronicum glaciale, Aster Amellus majus, A. longifolius formosus, Aubrietia grandiflora, Betonica grandiflora, Calochortus luteus oculatus, Caltha palustris flore-pleno, Campanula aggregata, C. Hendersoni, C. ranunculoides, Convallaria majalis, Coreopsis auriculata, Delphinium Belladonna, D. nudicaule, D. alopecuroides, Dianthus floribundus, D. neglectus, D. pungens, Dielytra spectabilis, Doronicum Clusi, Dodecatheon integrifolium, D. Meadia and var. album, Epiloblum pinnatum elegans, Erigeron macranthus, Fuchsia corallina, Gentiana scaulis, Geum coccineum flore-pleno, Helianthus multiforus plenus, Helleborus niger maximus, H. orientalis, H. atrorubens, Hemerocallis flava, Hepatica angulosa, H. triloba var., Hyacinthus amethystimus, H. candicans, Hypericum calycinum, Iberis corifolia, Iris germanica var., Jasonia glutinosa, Lilium candidum, L. chalcedonicum, L. tigrinum splemens, Lychnis chalcedonica plena, Meconopsis cambrica, Myosotis dissitifora, Narcissus Ajax, N. incomparabilis var., N. poeticus plenus, Nepeta Mussini, Enothera macrocarpa, Peonia ablifora var., P. officinalis var., Papaver nu dicaule, Phlox verna, Primula acaulis var., P. Auricula var., P. cortusoides, P. denticulata, Pulmonaria azurea, Ranunculus amplexicaulis, Saxifragaranulata fi.-pl., S. longifolia, Schizostylis coccinea, Scilla siberica, Sedum spectabile, Senecio pulcher, Sisyrinchium grandiflorum, Solidago Virgaurea, Scambrica, Spirzaa Aruncus, S. Filipendula plena, S. japonica, S. venusta, S. palmata, Statice latifolia, Trollius europeeus, T. napellifolius, Veronica prostrata, V. amethystinus, Viola cacullata, Tritoma uvaria glaucescens, Thaliturum anemonoides, Stenactis speciosa, Polygonum Brunonis, and Delphinium Keteleeri.

Keteleeri.

FRUIT TREES FOR WALL (Idem).—You do not say whether your wall running S.E. to N.W. will have both sides or only one available for the trees. The south-west aspect will be suitable for Plums and Pears, the former requiring to be lifted every three or four years so as to keep them fruitful. The Pears should be on the Quinco stock, and be planted 6 feet apart, and the Plums 20 feet. Plums.—July Green Gage, Green Gage, Kirke's, and Jefferson. Pears.—Jargonelle, Williams' Bon Chrétien, Louise Bonne of Jersey, Hacon's Incomparable, Marie Louise, Doyenné du Comice, and Beurré Diel. The north-east aspect would answer for Cherries—Early Jaboulay, Belle d'Orleans, May Duke, and Black Tartarian, with Morellos; also Apples—Devonshire Quarrenden, Ravelston Pippin, Kerry Pippin, Cockle's Pippin, Dutch Mignonne, and Sturmer Pippin. The Cherries should be on the Mahaleb, and the Apples on the Doucin stock, and planted 6 feet apart. We should have one each of the Cherries, one each of the two first-named Apples, and two each of the others.

Paraffein Stoye v. Hot-Water Pipes (Elleanach).—To exclude frost

PARAFFIN STOVE v. HOT-WATER PIPES (Elleanach).—To exclude frost from your conservatory with a parafin stove would be more costly than heating with hot water, and is not so desirable. You would find the cost for fuel less if you increased the quantity of piping, and the temperature would be more healthy and agreeable, as the pipes would not need to be heated so much as they are now.

BOX TREES DISEASED (Hr.F.).—The spray sent has the appearance of having been cut by hallstones, though it may be due to the unusual wet season. The remedy is, of course, more favourable weather. A dressing of leaf soil or thoroughly reduced vegetable refuse applied as a top-dressing over the roots would be advantageous in promoting more vigorous growth.

CONCENTRATED MANURE (J. Shepperd).—Not having seen the Manchester manure advertised we are unable to inform you where it can be obtained.

ROSES FOR EXPOSED POSITION (E. T. H.).—Gloire de Dijon, John Hopper, Jules Margottin, Souvenir de la Malmaison, Général Jacqueminot, Sénateur Vaisse, Madame Victor Verdier, Prince Camille de Rohan, Madame

Clemence Joigneaux, Marguerite de St. Amand, Comtesse d'Oxford, Marquise de Castellane, and Boule de Neige.

ROSES FOR HEDGE (Flora Bayley).—If the situation is very much exposed we fear the Roses will not succeed well. Your best plan will be to have a stout galvanised wire fence and cover it with climbers. Indeed, as you require evergreen Roses, you must have climbers such as Félicité Perpetué, Flors, Leopoldine d'Orleans, Bennet's Seedling, Dundee Rambler, and Spiendens. The ground should be dug deeply and be enriched with manure previously to planting the Roses. The Sweet Briar is hardy and makes an agreeable hedge.

agreeable hedge.

ROSES UNDER GLASS (A Lover of Rose Shows).— You may train the climbers down the roof if you wish to do so, but you cannot grow Roses in pots under a shaded roof. Until you have had more experience in growing Roses under glass we cannot advise you to attempt such early forcing as you appear to desire. First have your plants well established, only forcing slightly the first year. A good fine along the front of the house and across one end will afford sufficient heat for the Roses; but we doubt if you will have a supply of flowers such as you appear to anticipate during the month of March. Proper furnace doors and fittings can be had from ironmongers, their cost varies. Mr. William Paul of Waitham Cross has published a small work on Roses in pots, but we do not know the price of it. A pamphlet on Tea Roses has also been published by Mr. Ecroyde Claxton, Wavertree, Liverpool.

Liverpool.

IXIAS AND SPARAXIS (M. A.).—These are half-hardy builts from the Cape of Good Hope. The true Ixias are known from Sparaxis by not having, like it, a jagged sheath; from Babians, in having a dry seed-pod instead of a berry; and from Tritonia, by having the stamens inserted at the bottom of the petals instead of in the tube of the flower. They will grow in rough peat; the strong ones require very little sand, and the smaller ones want one-third sand in the compost. They succeed well in a warm border if sheltered from hard frosts and not allowed to get dry when they are if growth. When done flowering they may be kept in or out of the pots, after the leaves are withered, without any water, until fresh growth commences. They may be potted now, and should then be placed in a cold pit and protected from frost and cold heavy rains, and taken to the greenhouse or window after roots are plentfully formed. Many will do very well if planted in sandy soil and leaf mould, about 4 inches deep, in a dry raised border, and protected there from severe frost and heavy rains by litter, and any material that will throw off the water. Triteleias are quite hardy and will grow well in ordinary garden soil. Plant them at once. The Sparsea arisefolia will grow will in the position you name.

KAMES OF FRUITS (T. G.).—The Plum is Jefferson. (Connaught Subacriber).

NAMES OF FRUITS (T.G.).—The Plum is Jefferson. (Connaught Subacriber).

—The Pear is Flemish Beauty. (P.Q.).—No. I Pear is Beurre Chairgau; 2 we do not recognise. The Apple is, we think, Cox's Orange Pippin, but it is too hard and green for it to be named with certainty. (J.D.).—No one can name Pears so hard and imperfect; besides, you have greatly exceeded the number of specimens that we undertake to name. Our stipulation is that not mere than six fruits be sent at one time, and when many more are sent delay must occur in publishing their names, even if they are named at all. (J. Mackenste).—Belle Agathe. It is a peculiarity of this Cherry that birds never attack it. It ought to be about a third larger than those you have sent.

NAMES OF PLANTS (R.).—It is a pretty smi-double form of Chrysanthemum coronarium. (F. M.).—Coronilla Emerus. (S. C. O.).—Pernettya mucronata. (R. C. R.).—The large leaf is that of Aralia Sieboldi. We cannot name the other plant without flowers; we do not think it is Gundia simplex. (G. W. A.).—I resembles Adiantum concinnum latum; 2, Perrist ricolor; 3, P. cretica albo-lineata; 4, P. errulata cristata; 5, P. serrulata; 6, P. serrulata variegats. (R. P. W.).—The specimens sent did not show the characters sufficiently to be identified, owing to the flowers being gummed on to the paper. If you could send several flowers of each in a small box we will endeavour to ascertain what they are. They appear to be Helianthemums and not Cistuses. (South Devon).—The flowering spray is Leycesteria formosa, the variegated plant Abutilon Thompsoni. We cannot name the other spray without flowers. (Mr. Nevill).—It is the Snowdrop Tree, Halesia tetraptera, a native of North America. The spesific name signifies four-winged, and refers to the fruit. (M. J.).—I, A stunted form of Pinus Strobus; 2, Abies exceisa Clanbrasiliana.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

BREAKING-UP INFERIOR GRASS LANDS. (Continued from page 334.)

In continuing our subject we wish to say we omitted to state in our last illustration, that before all the turf could be burnt heavy rains set in and prevented the completion of the work upon one corner of the field for a month or six weeks, in consequence of which we could not plough the land. Where the land was cleared of turf the roots of the grass left in the land started again and made a thick mat of grass as before, and as we thought of a better and finer description than previously prevailed, and no doubt if we had given it a heavy dressing of ashes that the turf would have been much superior and more productive than it ever had been before. Our object in naming this circumstance is, that in those cases in pastures and park lands where some parts bear only rough coarse grass, that the method of paring the turf, burning and spreading the ashes, and if necessary some seeds sown for renovating the herbage, may with advantage be carried out without ploughing. Where the coarse turf only occurs in patches it would be very inconvenient if cultivated and cropped, inasmuch as it would

require to be fenced against cattle for the time. In the case, however, of paring and burning alone it would be for a short period only, and not interfere but slightly with feeding and other arrangements connected with the usage of the pasture. There are various causes which operate to produce these poor and brown patches on the pastures which are sure to be altered by paring and burning, especially when insects are the cause of it. For instance, the rook worm, as it is called, is a large grub which often breeds in certain patches, and the rooks rout up the turf to get at them, and thus leave the land bare and brown with decaying grass roots, &c. In some cases ants prevail to a great extent, which cast up their hills and prove a great impediment in cutting grass for hay. These or any other causes which make pastures uneven in appearance can best be altered and improved by paring and burning the turf, and with but slight and temperary desurbance to the ordinary menagement of the park or pasture lands.

ance to the ordinary management of the park or pasture lands. When the whole of a pasture, or a large portion of it which can be easily fenced off and brought under separate management, it may often be wonderfully improved by breaking up, as our next illustration will show. We had a very convenient and useful pasture near our residence with fine timber upon it, and certainly it was a very ornamental piece of grass land, except about 3 acres on the far side, which only produced an inferior class of herbage. We were quite aware of the cause of this, but for some years we hesitated to break it up, but after treating the pasture liberally with manure and compost we found it of little avail. We therefore determined to break it up, in order that we might drain it and chalk it, so that after cultivating and cropping for a few years we might lay it down to grass again, and thus have the whole pasture of the like quality and appearance. The soil was a strong clay at bottom but with a strong loam on the surface; therefore, instead of paring and burning as we had previously done with the breast plough propelled by men, we use the common plough with two horses, and cut the turf with the broad paring share attached. Instead of cutting the turf about an inch in depth as it is usually done by the men in "burn baking," we did not hesitate to cut the turf from 2 to 3 inches in depth, in order that we might be sure to destroy any insects in the land. At the same time this system furnished not only ashes enough to use on the land when broken up, but also gave us a good supply for use upon the farm in cultivating for root crops, which we thought would in some measure compensate us for the expenses of breaking up.

We undertook to plough up the turf and empleyed our usual gang of men to burn the turf at so much per acre, because such work is always best done by men who are accustomed to the system of stifie burning, and at the same time prevent any disturbance of the ordinary labour going on upon the farm. We fortunately had a fine dry time for burning the turf, and the quantity of the ashes produced was enormous; so much so that the third part only was used on the land the first year and fallowed in, another third part was stored and thatched in heaps at one end of the field for use the second year, the remainder was carted away and stored for use, and proved quite sufficient far drilling with our root seeds for several years. As we had to drain and chalk the land we kept it in fallow for the first year, in order also to thoroughly mix the soils by cultivation; in the antumn we sowed wheat and had a splendid crop, succeeded by stubble turnips which were fed off by sheep eating cake, dc. In the spring after spreading the sales we had in heaps, we sowed April bearded wheat, because harley would be sure to be overstrawed, and this crop of wheat proved about the largest crop we had ever seen. It was cut early and stubble turnips again sown and fed off as before, and then sown with black Tartarian cats; these were as stout a crop as could be grown. After this we prepared to lay the land into grass, and seeded it in the spring on a tallow surface, using a mixture of permanent meadow grasses and clovers such as we have recommended and intend to describe in an article upon the subject in this Journal at a future time, as adapted for various soils. The first summer after the grasses became strong enough to bear feeding with cattle the dairy cows were allowed to run upon it, but not the sheep, for unlike cattle they bite toe closely and injure the young grass, and until the grasses were firmly and permanently established sheep were not placed on the pasture. It is now twenty-five years ago that this pasture was relaid, and it has

fully realised.

We have given these illustrations for the purpose of teaching the home farmer how to avoid mistakes on the one hand, and how to take advantage of circumstances in his favour on the other. We, however, by no means advocate an indiscriminate breaking-up of inferior grass land, or indeed any grass land, because there are various matters to be considered before it should be resorted to, such as whether the land is intended to be converted into arable land in the future or relaid into permanent pasture. As a rule we can seldom justify the breaking-up of rich productive pastures, and where an occupier has been permitted to do so it is very seldom that it has ever returned to good pasture

as before, although when corn was dear it might have been a profitable transaction for a time. Almost all soils will pay for breaking up and burning the turf except sand and gravel. It is especially difficult to burn the turf of sandy land, for as soon as the vegetable matters become burnt the sand alone sinks down into a mass and puts the fire out by the exclusion of air, and a similar thing to some extent occurs in the case of gravelly soils. All inferior pastures will not pay for breaking up and converting into arable, especially on thin chalk soils; for such land, although furnishing only a scanty herbage, will by feeding with sheep keep them healthy, and by folding on the arable land at night time manure the outlying land at but little cost. We have, however, one more illustration to offer of the advantage of breaking up good loamy down land well situated and laying down the like quantity of poor outlying arable into pasture or sheep walk, as the downs are often called. We obtained permission for a tenant to be allowed to do this, and not only on account of the benefit to be derived from the conversion, but also of the situation of the fields, which were both favourably situated for the exchange. These fields of about 27 acres each, one being in down pasture and near the centre of the farm, were broken up and converted into arable; the other, being arable situated at the outlying part of the farm, was well prepared and laid into pasture or sheep walk, being sown with the finest permanent grasses. Large tracts of poor clay soil which were originally arable exist in various districts, particularly in the midland counties, and instead of being laid down with judgment had evidently, from the ridge and furrow being visible, been allowed to run to waste; and where dairy farms consist of this description of soil from 10 to 15 per cent. may be broken up and relaid, keeping up this proportion of land under culture until the whole has been relaid, which if properly done will greatly improve the letting value of the

WORK ON THE HOME FARM. Horse Labour.-Wheat must now be sown upon all heavy and cold soils. This work, however, may be deferred until the middle of November upon dry land, especially after clover lea, for we of November upon dry land, especially after clover lea, for we find the little white slugs very numerous; and by sowing the wheat a fortnight later than the usual time we may get frosts sufficient to prevent these enemies to vegetation from doing serious mischief. In ploughing the lea ground for wheat it should be pressed at the same time, when no doubt great numbers of the slugs will be buried and crushed to death. Where the work of ploughing and pressing is tablindhead the steep placet. work of ploughing and pressing is behindhand the steam ploughing and pressing is a capital substitute for horse power, and fortunately there are but few districts now without the steam tackle being available for this work. In those cases where the farm work is in arrear steam power will recover lost time, and it will be required oftener than usual this season, as, owing to the harvest having been so late, it has seriously impeded the work of the farm. We must still call attention to the advantage of doing some autumn tillage upon that portion set out as a root lain for next year. Particularly is it desirable to till the land intended for mangolds or early root crops of any kind, such as carrots, cabbage, and early Swedes; the remaining portion should be sown with seed of trifolium, vetches, rye, &c., which, however, should be sown upon the cleanest of the land, so that after these crops are removed there may be less horse labour required at the busy period of summer. In cleaning land for mangold and the other early root crops we may be enabled to clear the surface as late as early root crops we may be enabled to clear the surface as hate as the month of November, for if the weather proves open enough to work the scarifier, drags, &c., the accumulated weeds and rubbish may be carted away to heap, there to rot, for it is seldom that at so late a period the weather will enable the home farmer to burn the grass and weeds in the open field. This work may therefore the grass and weeds in the open field. This work may therefore be undertaken without reference to the burning of weeds. Of course the land would not be quite free from the roots of couch and water grass; yet after the surface has been cleared and the land laid up for winter by deep ploughing, the early root crops may be sown without ploughing in the spring, the land being prepared by the scarifier, &c., only. This plan has many advantages over spring-ploughed land, because it will always be moist enough in the driest seasons for the seed to vegetate, and the land will always be fine and kind, because we make use of the weather-beaten surface which has been ameliorated and prepared by the alternations of frost and winter storms. Storing or heaping of mangold will still be going on. It is, however, a good plan to save the horse labour at such a busy time as wheat sowing by pitting the roots in the field by casting them into heaps at regular distances, and cover them over with straw or seaweed and earth if they are to remain during the winter for feeding sheep in the field, otherwise they may have less covering and be drawn to

large store heaps at the farmstead after the busy period is past.

Hand Labour.—The work we have just been recommending is hand labour properly, but it was so connected with the subject of

horse labour that we could not well divide it. Swedish Turnips, too, may be pitted in the same way where they were early sown, and particularly where there is a head of game; these roots ought always to be covered in heaps in the field during the winter, and until they are required for feeding sheep, or be taken to the homestead for feeding cattle. Horses now should be fed upon roots, either carrots or early-sown and ripe Swedes, for nothing can justify the old plan of feeding farm horses upon all dry food during the busy periods of wheat and barley sowing. It is quite impossible for horses to do their work so well during the winter and spring months eating dry food only, besides which it is the cheapest way to use roots. Our attention was first called to this matter many years ago by a statement in the report from the county of Suffolk to the Board of Trade, in which it was stated as the common practice for the farmers to economise the feeding of horses by using only one bushel of oats per week per horse, the difference or substitute for a full allowance of oats being made up by carrots given with hay chaff; and it is not only economy in feeding the horses, but the advantage also of turning crops to the best account, for in feeding horses an acre of carrots being a full crop will go as far as five acres of oats, straw included. The sheep on the farm, particularly the fatting flock, ought now to be doing well by having a full allowance of cut turnips mixed with cake or maize meal. A fair proportion of hay chaff, much of the hay this year being damaged by rain, has little or no aroma, in which case it should be spiced when being cut into chaff and then cast up into heap for a day or two; this will give it an attractive aroma, and also improve the feeding value. We recommend the "Botanic Flavourer" and "farina," sold by T. Bowick & Co. of Bedford, as the best and cheapest article in the market. The same method of feeding may be applied to fatting bullocks as well as sheep, likewise for horses where the hay is cut

SPECULATION IN POULTRY SHOWS.

THE number of poultry shows held this autumn has considerably decreased from former years. Some of those which have been discontinued are regretable, as old-established and well-managed meetings; the greater part of them served no real purpose, and their want will not be felt. We have long foreseen such a sequel to the absurd multiplication of all exhibitions, and hall it with satisfaction.

We have so often given our opinion as to the circumstances under which shows should or should not be held, that we will not weary our readers by returning generally to that theme. We wish, however, to say a few words upon the, we fear, increasing tendency to speculation in shows. They ought certainly to pay, and we have often advocated their being held alone in centres of districts where some interest is taken in them, and where they have a chance of being financially successful. In many places, too, it is quite proper that those who give much time and trouble to their management should, if they are willing to accept it, receive some fixed remuneration for their labours. But there are other shows, generally small ones, and these we fear on the increase, which are simply started as gambling speculations. Subscriptions towards them are not infrequently got out of the neighbourhood under the pretence of encouraging poultry breeding, which practically all go into the pockets of the clique who manage them. We say practically, for we do not mean that the managers absolutely purloin the sums subscribed, but they so arrange things that they and their friends carry off the major part of the prizes. To begin with, all the best prizes are offered for such breeds as they possess; then they carefully watch the entries as they come in; if certain classes are thin they immediately buy cheap birds to win in them, and having the command of the entry book can of course make entries as late as they like. On the other hand they send postcards in all directions to the effect that the classes in which they do not care to exhibit are poorly filled, often when such is by no means the case. This may sound a fanciful description, but we have over and over again had proof positive of such tactics being pursued. Indeed we are sorry to say that if we have notice that some class is badly filled we generally conclude that it will be a peculiarly large one; but whatever chance there may be on either side, fanciers should on principle never li

The prize list having been thus arranged, no little gain from that source flows in to the promoters of the show. In some places the subscriptions are considerable and cover nearly all the prize money. The general management of a large winter show, including hire of hall, lighting, &c., is an expensive item, but the exhibitions to which we allude are generally summer ones, the cost of which is very small. Then the gate money, if the show be held at a time of some other attraction and the weather be fine, is often enormous. Perhaps there is a considerable per-centage on sales. The result is, that at times between prize money and general profits the managers pocket really large sums, which ought properly to be carried to the funds of a society to be

expended another year in better prizes, and so really encourage the breeding of poultry. On the other hand things sometimes turn out differently; a pouring wet day comes, or somehow the show does not "take," and entrance money is almost nil. What happens then? The prize money is often not paid; at others appeals ad misericordiam are made to exhibitors to forego their winnings. We do not for a moment mean to say that there are not cases in which after real failure every penny of prize money is honestly paid, and that by those who can ill afford it. We well know instances in which this has been done. Our meaning is that we object to speculation in shows. Formerly horticultural exhibitions were often got up this way; they have now, we believe, been entirely put down. There is much temptation to movers in them not to be honourable, or at least not to promote the interest

of poultry breeding.

Speculation in shows is intimately connected with speculation in buying birds for show alone. To what lengths the latter practice may lead has been unfortunately shown during the past week in the case of inhuman brutality to a bird with the sole object of winning a prize, most properly shown up and punished in a court of law. It is a sad pity that what should be an honourable amusement for honourable people, with all the while a really good and practical end in view, should be dragged by a few gamblers into ill repute. The poultry fancy is running considerable risk of making such a descent. Its fall may, however, be arrested if the bulk of fanciers who are upright and honourable ladies and gentlemen will only take the trouble to ascertain beforehand how shows which they patronise are managed. Those should alone be encouraged which are promoted by a society with real and definite aims, or which are undertaken by a committee containing known names, who not only guarantee the payment of all prize money, but that all surplus profits, after the deduction of reasonable remuneration for work, shall form a fund for the improvement of the prize lists of future shows. There are plenty of places with good exhibitions where these guarantees are to be obtained. If fanciers, in the true sense of the name, will not give themselves the trouble to discover and encourage them they will find their amusement of exhibiting gradually cease to be such, and will to a great extent have themselves only to thank for their loss.—C.

THE OXFORD POULTRY SHOW.

On Wednesday and Thursday in last week the eighth great Oxford Show took place. Of course after the miserable weather of the past season many of the chicken classes were not what we remember them in past years, still compared with other shows which we have lately seen it was a fine exhibition. The arrangements were much as usual: The poultry generally (they numbered altogether 850 pens) occupied the Corn Exchange, the fancy waterfowl being in the large gallery; a side gallery in which the baskets were formerly stowed was given up to the classes of dead poultry; the 1800 pens of Pigeons were in the Town Hall, and the connecting corridor was filled with large waterfowl, Turkeys, and selling classes. The attendance of visitors seemed hardly so good as in former years, still there are always to be seen at this Show a large number of evidently non-fanciers, which we always think a good sign for financial success. Apparently subscribers and donors of cups did not this year receive free passes and other tickets, which change ought to add considerably to the receipts. The management was, as it always has been, very good and orderly. The names of the owners of the birds referred to are placed in parenthesis.

Dorkings were by no means such classes as we have before

Dorkings were by no means such classes as we have before seen at Oxford. Neither the first (F. S. Lowndes) or second (Mrs. Troughton) Darks were fine. Though we liked the shape and short legs of both the cockerels, we liked the cockerel in third pen (B. Smith) for his white feet. On the whole we much preferred Messrs. Smythe's highly commended pen to any others, the cockerel of which was a grand bird. Silver-Grey cockerels were better than the pullets. The first cockerel (R. A. Boissier) is a magnificent bird all round save from a blemish, a wry tail; we have seen him before in a first-prize pen, and have remarked on this point. The two other pairs of winners (Plummer & Ruttlidge) are fair birds. The first White cockerel (Mrs. Logan) is very good, short-legged, and full-breasted; the other winning pairs (Mr. Hayne and Miss E. Williams) worthy of their positions. Cuckoos this year are absent. Spanish are much better than we have before seen this year. The first-prize pen (Jabez Walker) are very remarkable for their fine condition, for the quality of their faces; the cockerel, too, in the third-prize pen (J. F. Dixon) had a fine face but not so refined as the first. Cochins.—First in Buffs (G. H. Wood) a good pair of lemon-tinted birds which have won before; in the second-prize pen (H. Tomlinson) is a cockerel promising one day to be very fine. Among the pens of Partridges are many birds which promise in another month's time to make grand cockerels; at present they are backward. The pullets are forwarder—first (C. Brown), and third (J. Wood), were very good. Whites.—The best pen (W. Steven) of Cochins in the Show were a pair of Whites, short-legged, fluffy, and pure in colour. They changed

hands at a high figure, we heard £30. hands at a high figure, we heard £30. The second Whites (H. Tomlinson), too, were a good pen and large, but in shape not quite so much to our fancy. We should have been inclined to give a place to the pair of good Blacks which were very highly commended (W. Badger). Brahmas.—The cup for Darks (H. R. Wiggins) went to a pair the pullet of which we cannot notice, for we did not see her. The cookerel was a magnificent bird all round with what is seldom seen, the finest foot-feathering yet soft hocks. The second pair (Miss E. Shuter) were good, the pullet of a fine shade of colour but deficient in pencilling towards the throat. These two pens were decidedly ahead of the rest pullet of a fine shade of colour but deficient in pencilling townshe the throat. These two pens were decidedly ahead of the rest. In Lights the cup pen (G. H. Wood) contained the cockerel which won at the Dairy Show, a neat and shapely bird all round but with terrible hocks, the pullet very fine; the other winning pens (P. Haines), good in some points, were not very well matched pairs. Langshans.—Eleven pens were entered; we should fancy the first-prize pair (R. H. Bush) were well selected from their admirers' point of view. Game were, as usual at Oxford, an immense collection from the valuable prizes offered for the breed. Nearly 150 pens were entered. Mr. Pope again won in Black Red cockerels with a striking bird, which quite reminded us of the wondrous bird he brought out two years ago, which created so much attention from his frequent change of owners at enormons prices; second (S. Matthews) a fine but young bird; fourth (F. A. Nelson) was, we heard, the Dairy Show winner, which shows that Oxford has been more successful in briging out the best birds of the year. Black Red pullets were another good class. First (S. Matthew) good all round; second (T. P. Lyon) very lengthy but not so neat; third (J. H. Caton) a coarser bird. Brown Red cockerels were not so good as the Blacks. The 55 ctp for best unskinned Game cockerel went to the first in this class (E. Wells), a good bird all round, though some good judges found much fault with him; second (J. Chester), a good bird, hardly the modern fancy in shape. Brown Red pullets were a large and good class; first and second (A. Fludyer & S. Matthew) most remarkable birds. In the any other variety class of Game Duckwing cockerels were first and second (R. Garnett & J. F. Walton), both nice birds; a capital Pile third (J. Colgrove). Two Pile pullets won (J. Colgrove) in the next class. In the undubbed cockerel class a very fine Pile won (J. Colgrove).

Hamburghs made good classes for the south of England, between sixty and seventy pens being entered. Golden-pencils came the throat. These two pens were decidedly ahead of the rest. In Lights the cup pen (G. H. Wood) contained the cockerel which

sixty and seventy pens being entered. Golden-pencils came first, first pair (Mr. J. Rawnsley), both very good in colour. We specially liked the cockerel; the second (Messrs. T. & J. Kidson) pullet was beautifully barred, we thought her the best pullet in the class. Silvers were better than the classes of them we have seen of late. The cockerel in the first (H. Digby) pen was acapital bird with well-barred tail, the pullet a bird with small and neat pencilling. The cockerel in the second (W. Reddihough) pen was not in good condition, the pullet very well marked; the third (J. Rawnsley) cockerel took our fancy. Golden-spangles were a large class; in the first-prize (R. W. Bracewell) the cockerel was a handsome bird in carriage, and in fact in all points, the pullet fairly mooned; second (R. W. Bracewell) a sickly-looking cockerel with a very handsome pullet, the best we thought in the class. Silver-spangles decidedly a good class; the first (G. Mitchell) pair were very fine in mooning, the spike of the cockerel's comb not so good as it might be, but we prefer this to those extraordinary made peaks so often seen; in the second (J. Rawnsley) pen, too, was a very good cockerel, and in the third (H. Beldon) as forward a one as any in the class. The first (J. W. Kelleway), Blacks were very perfect in comb and figure, but their position as regards the light was not favourable to the sight of their colour. We admired the pullet in the second (J. Pickup, jun.) pen. Polands.—Golden had a class to themselves, we fancy aided by the liberality of some fancier, for the competition in Silvers is now generally greater and closer than in the Golden variety; the first and second (J. Rawnsley and E. Burrell) prize pens of the latter variety were both rich in colour and good in crests. In the next class Silvers were first and second (A. Smith & G. C. Adkins), the pullet in the first pen being magnificent. White-crested Black had to be content with a third (J. Rawnsley), though they were a good pair and well shown. Houdans are now g

giness. Leghorns continue to look up. The first (E. Gibbs) pair of Browns were not very large, but beautiful in condition and well matched. The ugly yellow lobes seem to be gradually got rid of. The first Whites (A. D. Esmarch) were a beautifully rid of. The first Whites (A. D. Esmarch) were a beautifully shown and pretty pair. Andalusians are another rising breed; we do not wonder at this, for they certainly are most beautiful, and non-fanciers always seem taken with their colours. First were a pair (Rev. S. Ashwell) which we think we have not seen before, good all round, well laced; second (Mrs. M. A. Wilson), a handsomely formed cockerel with a pullet hardly his equal. Sultans are creeping into notice, certainly a well-shown pair, are very attractive. The prize pens seemed to us very even, the first (Lieut. Jenkins) winning from being well through the moult and in good condition. Any other variety were interesting. First (Lieut. Jenkins) winning from being well through the moult and in good condition. Any other variety were interesting. First (Rose Hubbard) capital Scotch Greys; second (G. Furness) good La Flèche; third (J. C. Fraser) what are called Havanas, extremely like the produce of a Silky and some small black fowl; we would not encourage the breed. There were some good Black Minorcas in the class, some good Silkies, and some white birds called La Flèche. Bantans.—Game were for these days numerous, twenty-four pens of Black Reds put in an appearance. First (E. Walton) a beautiful pair, the cock an old bird in wonderful condition; we noticed a good pullet in the third (W. F. Addie) pen. The winners in the class for Brown Reds seemed all good. Piles came in first and second (W. Cannon & W. F. Addie) in the "any other Game" class. Black Rose-combed has sixteen entries. We think smallness of size in this breed has of late been much We think smallness of size in this breed has of late been much We think smallness of size in this breed has of late been much sacrificed to earlobes; the first prize (H. Stanworth) pair might with advantage be smaller, otherwise they are a pretty pair. Sebrights are perhaps better than ever in lacing but much oversize. First and second (M. Leno) were Silvers, third (M. Leno) Golden. Beautiful little Pekins (H. B. Smith) carried all before them in the "variety" Bantam class.

Golden. Beautiful little Pekins (H. B. Smith) carried all before them in the "variety" Bantam class.

Ducks were well provided for with six classes. Aylesburies were as good a class as we have ever seen. The first-prize (Messrs. Fowler & Co.) pair, we believe birds of the year, were enormous. Rouens were very numerous, no less than two dozen pens being entered. The first (T. Wakefield) pair again were easily ahead for their enormous size. Pekins and Cayugas were combined. The prizes all went to the former variety. Black East Indian have gone down. It seems difficult to get good lustre and small size combined. We were pleased to see that one of the oldest, we believe the oldest fancier, in England of the breed (Mrs. M. A. Hayne) took first honours. Carolinas were first (H. W. Boutcher) in the next class. Turkeys and Geese were not large classes, but the winners in both classes were of good average size; the first Turkeys (W. Wykes) being bronze, the first Geese (E. Snell) Toulouse. Mr. Sainsbury judged the waterfowl alone. We believe his awards gave great satisfaction, and it is certainly a far better plan to have one judge specially skilled in these classes, and not put them at the end of a long book of classes to be adjudicated on by a tired judge, as is so often the case. often the case.

Dead poultry were a new feature in the Show. Fourteen pairs of fowls were entered. The Langehan breeders will probably feel elated on seeing in the prize list that their favourites won. We

feel elated on seeing in the prize list that their favourites won. We cannot say that they looked so tempting as two nice small-boned Dorking pullets, which were second (T. C. Burnell). Some very fat Ducks and Geese appeared, and but one Turkey.

The show of Pigeons was so vast that after a careful examination of the eight hundred pens of poultry we found it impossible to scan them with sufficiently critical eyes for our notes on them to be of value. As usual at Oxford nearly every variety was well represented, and some classes were extraordinarily good and well filled, especially those for English Owls, Dragoons, and Antwerps. The latter variety filled no less than 260 pens.

The Judges were for poultry Messrs. E. Hewitt, R. Teebay, and J. Martin; for Waterfowl Mr. G. S. Sainsbury; for dead poultry Mr. J. Turrill and Mr. P. Hicks; and for Pigeons Messrs. H. Allsopp, F. C. Esquilant, P. H. Jones, and Capt. Norman Hill.

HOW TO TREAT CONDEMNED BEES.

DISCOVERY OF A NEW METHOD OF GIVING ARTIFICIAL POLLEN,

COTTAGERS adhering still to the miserable and wasteful plan of burning take up, as a rule, those stocks that are too light to stand the winter. If such were allowed to remain they would consume all their little horde of sweets and then starve. The cottager therefore is right, from his point of view, in destroying the bees, and thus securing the honey for his use. The poor insects marked out for destruction are commonly known as condemned bees. If in autumn 4 lbs., or thereabouts, of these turn-outs—i.e., the united bees of three or four skeps—be put together into a hive and fed liberally they will quickly build comb, raise brood, and establish themselves so as usually to winter well and make some of the best colonies of the apiary in the spring. The wax secreted for the building of the comb is produced from the sugar given as food, while the bees gather, if the operation of building-up be not deferred till too late in the season, sufficient

pollen to enable them to raise a fair, if not even a large, amount

Some experiments with these condemned bees, which I take to be in their results exceedingly instructive, I will now recount. On September 19th I placed 42 bs. of bees in a large and well-protected hive, in the frames of which narrow guides only were provided. The first two days they took 4 bs. of syrup, but afterwards for seven days they were provided each evening with a filled bottle containing 3 ibs. 11 ozs. of syrup. They built comb of great evenness and whiteness, which now more than half filled of great evenness and whiteness, which now more than half filled the bive, yet the queen laid but few eggs. The reason, upon theoretical grounds I was convinced, was lack of pollen. Very little at this date could be found in our neighbourhood, as the land is mostly under cultivation. If the pinch for pollen was already felt, how was the greater difficulty of providing sufficient for early spring breeding to be met? I placed trays of pea flour (pea flour I first pointed out as a fine substitute for pollen, since it stands in the front rank as a flesh-former) near to the hives, prinkling cheff over the pea flour, as is now generally well undersprinkling chaff over the pea flour, as is now generally well understood, to give the bees a standing place while gathering it on to the hairs of the thorax. A stock of Ligurians that had fed from these same trays in the spring started at once, and carried it heavily, but my newly arrived blacks seemed unable to learn the nature of the boon offered them, only an occasional bee loading itself. I now reflected that the pollen of anemophilous trees—i.e., trees fertilised by the wind—is not sticky, so that the wind soon separates it from its anthers and blows it on to the adhesive separates it from its anthers and blows it on to the adhesive pistils of its flowers; while the pollen of entomophilous trees—i.e., trees fertilised by insects—is sticky, and so can the more readily be made into pellets by the different species of bees, and added, as an experiment, to my pea flour a small quantity of pounded sugar to increase its adhesiveness. It was now perhaps loaded more easily and quickly by the Italians, but the blacks, as before, listened not to my wooing. The problem to be solved took this form: We can give sugar without asking our bees to leave their warm cluster to take it, but artificial pollen, even if accepted, needs the bees to quit the hige and expose themselves often to needs the bees to quit the hive and expose themselves often to a needs the bees to quit the five and expose themselves often to a temperature so low that many must perish; while the weather, when nitrogenous food is essential, may be such as to altogether prevent any outside gathering of it. How, then, can pollen or its substitute be given within the hive?

In the natural way bees collect the pollen on the breast, and transfer it by the metatarsal brushes to the pollen pockets on the tibiæ; but to accomplish this, as may be seen by watching a bee over a flower, two of the three pairs of legs are required, and since the bee cannot stand on the remaining rair this packing is

a bee over a nower, two of the three pairs of legs are required, and since the bee cannot stand on the remaining pair this packing is of necessity effected on the wing. I, in order to meet this requirement, placed a small tray of pea flour on the top of the hive, and added a small covered flight chamber, so that the bees coming from the top opening might have room for the hovering flight while packing. This was partially successful, but had this drawback—that the warm air of the brood nest was leaking freely away into the chamber above. It now occurred to me that bees, when natural pollen is stored place over it a layer of honey and when natural pollen is stored, place over it a layer of honey, and when natural pollen is stored, place over it a layer of honey, and then wax seal it. After extracting the top of the stored pollen, saturated with honey, is constantly seen. Can it be wrong, therefore, to place the pea flour mixed with honey or its equivalent at once in the cell, and so save the bees all the exposure, labour of gathering, and storing it? I now mixed some pea flour with syrup, containing the small quantity of salicylic acid I have previously recommended into a paste and removing a comb syrup. containing the small quantity of salicylic acid I have previously recommended, into a paste, and, removing a comb, applied it with a flat knife, as boys at school sometimes apply butter to bread to fill up the holes. About 3 ozs. of pea flour were soon put into the cells and the comb returned. Two hours after upon removing the comb, to my intense delight, the bees had sucked out the excess of syrup, and had packed my pea flour down in the most beautifully regular manner, as though it had been pollen gathered in the natural way. The problem was now solved. What with much labour, and probably much loss, could only have been accomplished by the efforts of hundreds of bees had been done through my help by a few bees with comparatively only have been accomplished by the efforts of hundreds of bees had been done through my help by a few bees with comparatively no exhaustion, and actually no exposure. The next day the greater part of this pollen had been consumed, while the dry starved appearance of the brood, well known to those who have overswarmed artificially, had passed away. Giving doses of pollen as needed the breeding quickly became rapid, and that hive has now not only a very large quantity of brood, but comb-building has again commenced.

On the 8th inst. I put 42 ibs. of bees taken from five skeps into an empty hive and fed freely, and on Saturday the 11th I examined it. Comb had progressed well, and eggs were laid. As I removed a comb and pasted my pea flour mixture into it I felt removed a come and pasted my pea nour mixture into it I felt some compunction in marring its spotless purity. On Monday the 13th another examination was made, when I expected to find the pollen packed, as in the other hive under experiment; but, to my astonishment, in the forty-eight hours almost the whole of it (about 3 ozs.) had been consumed. There were yet no hatched eggs that I could find. The bees then, under the labour of combbuilding needed the nitrograms food to make good the work. building, needed the nitrogenous food to make good the wear of tissue involved. The microscope showed pollen granules in the

stomachs of wax-workers, which gather naturally. These bees had made comb on sugar only, but no doubt were growing in stomachs of wax-workers, which gather naturally. These bees had made comb on sugar only, but no doubt were growing in some sort emacisted under the process, and the pea flour supplied the place of the pollen they would have consumed whilst gathering their sweets had this been done in the normal manner. What an absolute refutation this gives to the notions of those who assert that bees never consume pollen, a statement which has no better base than a guess, and which is utterly at variance with all scientific theories of diets. This later hive, worse off as the season is more advanced than the one first named, is going ahead splendidly, and is raising great breadths of brood, and is receiving its pollen as occasion requires. To-day, the 25th, it divided 6 ozs. of pea flour, exclusive of syrup, with the other stock mentioned, and this amount no doubt by Monday will be much reduced. I am quite willing to show these bees to any really interested at such times as they can be examined without risk of much chill. We see here a way of building up bees almost without regard to the season, for not only now can we give syrup, which is but half a diet, but pollen likewise, without one wing being moved in the chilly outside air. If any reader can assist me in obtaining another 4 or 5 lbs. of bees for an experiment yet to commence I am prepared to give fair payment and my best thanks for the assistance. The judicious use of this plan in promoting breeding in the spring will no doubt lead to great results, upon which, all going well, I may in due time make some comments.—FRANK R. CHESHIRE, Avenue House, Acton, W.

THINGS KNOWN AND THINGS UNKNOWN.

THINGS KNOWN AND THINGS UNKNOWN.

GOVERNMENT and organisations in the kingdom of a bee hive are things beyond the reach of human knowledge. While united effort and perfect order are remarkable features in the conduct of a community of bees, who knows aught of individual authority and rule? All seems to go well and harmoniously on the lines or laws of equality and fraternity. The queen herself—the great bee of the hive, which receives the greatest possible homage and attention—is subject, at least in appearance, to the community which she so faithfully and laboriously serves. Queen and servant she is, but not governor. It is known that the monarchy of a bee hive is neither absolute nor hereditary.

The industry of the honey bee is a fact known in all lands, and is the theme of poetry and song amongst civilised and enlightened communities. It is hardly possible to form an adequate conception of the industry of bees. The amount of work done by a swarm in the height of the season cannot be measured or compassed. A swarm has been known to gain in weight 10 fbs. a day—20 lbs. in

swarm has been known to gain in weight 10 bs. a day—20 bs. in two days; but who can tell the amount consumed to meet the waste and wear sustained in the manifold activities and labours both at home and abroad of such active creatures as bees? The amount of food consumed by bees during a day of hard work is great, and should not be forgotten when their industry is under great, and should not be forgotten when their industry is under consideration. Even at night in summer there is a considerable loss of weight by the escape of moisture of a strong full stock through the hive and by the door. At one time many able beekeepers believed that the queen alone distributed her eggs; but many now know that the bees assist in this work by removing the supernumerary eggs from the cells in which they are found and placing them in empty cells. But the question of how much heat is necessary in hatching brood remains unsettled. Brood evidently is brought to perfection at the swarming season in a high temperature, and often in February at comparatively a very low one. This is an interesting question for experiment: also the question of how much pollen is used in rearing brood, and how much or how little is eaten by adult bees. A few tangible facts about the consumption of pollen would tend to remove doubt and difficulty, and clear off the darkness that surrounds the subject. Can anyone supply the Journal with them?

Though I have never been fortunate enough to possess a fertile

Though I have never been fortunate enough to possess a fertile worker, or found proof of the existence of one in my apiary during half a century of observation, I have no doubt of the fact that fertile workers have been occasionally found by other apiarians; but the proximate or procuring cause of fertile workers is one of the many mysteries of bees. A few days ago the following letter was sent to me by a bee-keeper in Mythturroyd:—"Dear Sir,—Can you give any information on the following subject? I have a hive without a queen containing eggs and brood. I took a swarm from it in July, when it had two cells with ripe queens; where they have gone I cannot tell. It has what some call a fertile worker. I have put the bees in a glass hive, and have seen the bee that lays the eggs; to all appearance it is nothing but aworker. If I lose sight of it I cannot pick it out again till it enters a cell. It first looks into a cell, then backs in just the same as a queen. None of the other worker bees do that. I am confident it is a common worker, but how it is that it can lay eggs I cannot tell." fertile workers have been occasionally found by other apiarians I cannot tell."

One of the greatest marvels of bees is their wax-making powers. It is well known that wax is a secretion and excretion of bees; that the work of secreting wax goes on both by day and night— in the fields as well as in the hive; that during the comb-building season hundreds and thousands of bees may be seen and caught in

returning from the fields with four, often six, plates or scales of wax each half excreted or thrown off from the rings of the under sides of their abdomens. The quantity secreted, the way and apparent ease of excreting wax, are alike wonderful. The mysterious marvel of all is the fact that this wax-producing power is voluntary—put into action by the will of the bees. This may be voluntary—put into action by the will of the bees. Ins may be proved in many ways, but simply by putting a swarm into an empty hive. The bees at once commence to make wax, and in less than twelve hours some comb is built. In honey weather the hive may be filled in less than twelve days. If another swarm be put into a hive full of combs the bees commence to fill them with honey, but the bees make no wax save, perhaps, a little for cell-lids to cover the honey and brood. In comb-building a great many of the wax plates fall on the boards and remain there un-used. Their presence and accumulation are signs of health and prosperity. In full hives few wax scales are formed and fewer lost. If wax were not a voluntary secretion much honey would be consumed and wasted in the production of wax when it is not needed. In covering cells of brood the bees use materials of the same colour as the cells. If the brood combs are dark in colour the covers are dark too. Why this is done is left to conjecture.— A. PETTIGREW.

FOUL BROOD.—It is supposed that there is not one hive in fifty that will survive the winter without food, and it is feared that foul brood is more than commonly prevalent. I have one hive affected. I have never before seen it or had it in any of my hives. In ordinary I have never before seen it or had it in any of my hives. In ordinary thriving hives there are three different substances to be seen in the cells—namely, honey, pollen, and young bees. In the case I refer to now there is a fourth substance, and when the lid is taken off the cell there can be taken out a sticky brown stuff. It appears here and there in a hive, and is the worst disease that affects bees, and was until lately reckoned incurable. Mr. Frank Cheshire, an able and pleasing writer on bees in London, sent me the only known cure—salicylic acid—to mix among the food.—James Shearer, Cairnie.

OUR LETTER BOX.

FREDING HIVE (Busy).—It is difficult to say how long you should go on feeding, because we have no clue to the mode adopted. From your letter it would appear that you administer food at the entrance by means of troughs. This is at best a poor way of feeding bees, because of the very small quantity which can be administered at a time. In this case you must not cease feeding after such a season as we have had till the frost comes, and you must resume it again when the weather is open in the very early spring. But we should advise you to make a hole at top of your hive and to feed them by bottle, carefully covering them with an empty hive and stopping up every crevice, so as to prevent the ingrees of robber bees. We would not advise you to smoke your bees in the way you have attempted, but a little smoke will be necessary if you make a hole in the top of the live. Mr. Cheshir's article on page 337 will afford you much information. See, also, the rep'y to "Subscriber" on page 538.

REMARKS.

REMARKS.

22nd.—Foggy morning, turning to drixnling rain by 10 A.M. till 2 P.M.; little finer in afternoon; very damp evening.

23rd.—Damp dull day; drixnling rain at intervals in morning; dull but tair afternoon and evening.

24th.—Very clear and fine in early morning; damp and drixnling rain after 1 P.M.; 4.50 P.M. to 5 P.M. sky bright and clear; 5.15 P.M. shower; damp cloudy evening.

25th.—Very bright fine day; foggy evening, clear at 11 P.M., and mesonlight 26th.—White frost in early morning; fine bright morning; rather cloudy in afternoon, few drope of rain 5.30 P.M.; slight misty rain in evening, but no measurable quantity.

27th.—Dull in early morning; very fine bright day; moonlight evening.

28th.—Fine but dull cloudy day.

Very ordinary autumnal weather; rather warmer than the previous week.

—G. J. SYMONS.

COVENT GARDEN MARKET .- OCTOBER 29.

LARGE importations of Apples are now reaching us from America, considerably affecting home supplies, and in the case of common sorts rendering them quite unsaleable. Trade keeps quiet, prices being generally below

From observations taken near London during forty-three years, the average day temperature of the week is 51.1°; and its right temperature 34.8°.

CLOSE VERSUS WIDE TRAINING OF WALL FRUIT TREES.

WING to the extremely unfavourable season for ripening the growths of fruit trees the above subject appears to me to merit great consideration; and now that the pruning period is approaching, the time seems opportune for directing attention to the importance of thin training as the first essential requisite for securing ripened wood. Few persons, I presume, have cause to complain that their trees,

when healthy, have not grown freely this year, for in most cases they have grown luxuriantly, but how to get the growth matured is another matter. I do not presume to solve this problem as regards the present much too green and succulent growth, but I think I may venture a suggestion that may be of use for the next and future

In the first place, then, it is my opinion that the generality of wall trees are allowed to carry twice the quantity of wood required. This perhaps may not be very apparent during winter when the leaves are off the trees, but in summer is it not a very common occurrence to see the branches of wall trees so closely trained that the leaves overlap each other and hardly an inch of the wall can be seen? Many indeed seem to pride themselves in being able to hide every inch of the wall. Now, in a season like the present I consider this a great disadvantage to the trees, and a sure way of securing unripe wood. Under this system of close training the wood is never exposed to the sun until the leaves commence falling in autumn, then it becomes necessary to sweep off some of the leaves to enable the wood to be ripened. It is quite impossible that the wood can have ripened when the leaves were covering it; but were the branches trained so thinly that everyone was quite clear of the others all through the season we should hear less of badly ripened wood, and any unnatural process of trying to ripen the wood late in autumn would not have to be resorted to. If every shoot were fully exposed to light and sun during the whole period of growth the wood would be matured by the time the fruit was ripe, as is often the case with thinly trained Vine shoots.

For some time we have been observing and taking note of some of our thinnest trained wall trees, and comparing them with those having their branches growing more closely together, and so far as fruitfulness is concerned it is decidedly in favour of the thin-trained trees. I am referring to Peaches, Apricots, Plums, Cherries, and all other fruits against walls. Some of our most scraggy Peach trees with branches a foot apart, or in some cases more, have produced more fruit this season than the most luxuriant-looking trees, and we can attribute the difference to nothing so much as the close training of the latter.

The system of thin training applies, no doubt, with greater force to trees grown in cold districts than to those grown in what is termed the "sunny south." During ordinarily fine seasons good Peaches have been ripened in favourable localities when the trees have not been trained thinly; but

even in those cases it is fair to assume that the fruit would have been still finer, and the wood better matured, if the wall had been less thickly covered and the bearing wood had been less densely shaded with foliage. Even in the most favourable summers and sheltered positions and warm localities trees on walls, I apprahend, would not be injured if a thinner system of training were adopted; while in less favourable districts—indeed I may say in the great majority of gardens, the change suggested would be unquestionably advantageous both to the trees and their owners.

Another disadvantage of close training is the favourable harbour it affords for insects, which include woodlice, snails, red spider, green fly, &c. Under a thick covering of leaves all these often do much harm before they are observed, and then it is not easy to eradicate them. When the branches are widely trained the insects have little means of hiding, but are readily seen and can be destroyed before they do harm.

As soon as pruning time comes this winter we intend cutting quite half of the wood out of many of our wall trees, and no branch will be left se close to snother that the leaves of either will touch; and next summer, when the young wood is being made, more of it will be removed than we have been in the habit of taking out. By adopting that practice we are confident, from what we can see now, that the trees will be cleaner and better ripened than they are now, and that better crops and finer fruit will follow.

Peaches and other fruits under glass will be treated in a similar manner; for although the growths of trees under glass necessarily become more fully matured than those of trees in the open air—that is, if the fermer are not shaded and are generally well managed, yet I do not hesitate to assert that in at least two-thirds of the Peach houses in this country the trees are more crowded than is needful. In proof of this I may point to the extraordinary number of fruit that has often to be removed to enable those remaining to become fully developed. Would it not be in every way better to remove a portion of the growths that are manifestly not wanted than to permit them to grow to such an useless purpose as producing fruit to be removed in a small green state, leaving, be it observed, as too often is the case, the then fruitless growths to shade the parts that are fruitful?

It is not unusual for the inexperienced seeking information on training fruit trees to ask how far the branches should be placed asunder. The question cannot be answered in the form of an arithmetical reply of so many inches; but everyone may decide the question for themselves by consulting the foliage of each tree, which is an unerring guide. It has been stated in the Journal before, and the formula cannot be too emphatically repeated, that the distance between shoot and shoot should be slightly grester than the length of the leaves, including the footstalks, of any tree in question. If this mode of training were generally adopted the cultivator would have done all in his power to prevent overcrowding, and if the wood of the trees under his charge did not then become matured he would have less to reproach himself with. Bad seasons often teach wholesome lessons, and one of the most useful lessons suggested by the present

NO. 1623.-VOL. LXII., OLD SERIES

NO. 971.-VOL. XXXVIL, NEW SERIES.

year is the one under notice—namely, the importance of training wall fruit trees more thinly than is commonly practised in the majority of gardens.—J. MUIR.

DOUBLE PRIMULAS.

To the amateur who has a small amount of glass and heat at his disposal double Primulas are invaluable, as they do not require a high temperature during the winter months. there is sufficient heat in the house to exclude frost and to prevent the foliage decaying they will succeed well provided other details of cultivation have been well attended to previously. In wintering the plants it is necessary that they should not stand too close together, and if the stage they are placed on is closely constructed it is best to stand them on inverted pots, so as to permit a free circulation of air between them and prevent damping. It is well to ventilate freely on all favourable occasions, and place the plants as near as possible to the glass. A house facing northwards is most suitable for them, but that is not a necessity.

The best time to propagate them is as early in the spring as possible, say about March, so as to obtain good specimens before autumn. Take off the cuttings with as much heel as you can, and remove any decaying scales there may be upon them at the base, and place them singly and firmly in thimble pots, well drained, and filled with a compost of gritty loam, sand, and a little soil finely sifted; then place them in a gentle bottom heat, not more than 65°. If the temperature of the bed is much higher than that they are liable to decay; if about that

temperature you may expect 90 per cent. to root.

When the small pots are filled with roots at once shift the young plants into 4-inch pots, clean and well drained, using gritty fibrous loam and leaf soil, about one part of the latter to two parts of loam, with a good admixture of road sand if obtainable, or sharp silver sand. This will be about the beginning of May. Keep the plants well supplied with water, as they will grow rapidly until they require another repotting, which will be about the middle of June, when they may be potted into 6 or 8-inch pots, employing a compost of loam, with well-decayed cow manure instead of the leaf soil, and a copious supply of sharp sand. Pot them firmly and low down in the pots, otherwise they get so loosened that they are apt to be broken off; and there are other advantages by potting them deep, as they more readily produce roots, and may be easily divided. After this potting they may be placed in a cold pit or frame in a shady position as near the glass as possible, shaded from the sun by means of tiffany or similar material. Keep them well supplied with water, giving occasionally liquid manure. They may remain in these pits till the end of September in ordinary seasons, and during August and September they grow very rapidly. They much enjoy the dewy nights and warm days. We frequently remove the lights from the frame when there is no likelihood of much wet, and the benefit resulting from such treatment is remarkable. You may secure plants in one season quite 18 inches across. The varieties enumerated below are the best in cultivation.

P. sinensis alba plena.—This is the oldest form, and is still much appreciated and well worth growing, but it is far super-

seded by the next.

Fimbriata.—This is a splendid white-flowered variety, producing very fine and double flowers, pure white when first expanded, with the edges beautifully fimbriated. The flowers are larger than the old White, and the plant has altogether a better constitution. For all purposes this variety is much to be preferred.

Rubra plena.—As a companion for the last this is indis-ensable. It is free-flowering, producing large very double

flowers of a pinkish red colour, and very fragrant.

Miss Eca Fish.—This is a new variety. The trusses and flowers are large and borne well above the foliage, of a rosylike colour passing to blush, with a well-defined white margin. This is a very elegant variety, and we can heartily recommend it as worthy of the most careful attention for cool houses. It is a free and strong grower.

Atro-rosea.—A free-growing variety, producing large trusses of well-formed and very double flowers of a deep rose colour; one of the handsomest of that series.

Magnifica.—Truly a very fine variety; a great improvement on the old Red. The flowers are very large and very double, with the edges of the floral leaves prettily fimbriated.

Blushing Beauty.—Very similar in growth, flower, form, and size to the white Fimbriata; but the flowers are all

suffused with a decided blush colour, which renders it very

charming. It is very floriferous, and not at all delicate.

King of Purples.—In this variety we have a grand addition, for while it bears large well-formed flowers they are also very deep in colour, and assume quite a purple tinge. One of the most distinct and handsome.

Rubra grandiflora.—A superior variety; in fact, we have heard it termed the best. The flowers are of a reddish pink colour, well formed, and as large as small Chrysanthemums.

It should be grown abundantly.

Princess of Wales.—A distinct variety producing good double

flowers, which are occasionally striped with rose.

Mrs. Eyre Crabbe.-This surpasses the last, and both as to its distinctness and beauty too much cannot be said. The flowers are well formed, very double, white, spotted and flaked with rosy carmine.

Emperor.—In this variety we have something very superior and different from the others, inasmuch as it belongs to the Fern-leaved varieties. The flowers are rosy red, large, and very double; finely fimbriated. This is one of the grandest of all.

*Empress.**—As a lovely companion to the last this should be

secured. It is also a Fern-leaved variety; trusses large, bearing fine flowers, double, white, and exquisitely fringed.-T.

KEEPING GRAPES.

THOSE who acted in accordance with the advice I gave in the Journal for the 10th of July, and made up for the deficiency in the natural temperature by the help of fire heat, will now have the wood of their Vines fully ripened. The foliage of Hamburghs will have put on its golden colour, rivalling even our beautiful Tulip Trees; the Muscats will have a mixture of russet and gold; Barbarossa, streaks and blotches of intense fiery scarlet. Lady Downe's and Mrs. Pince have the same colours, but are not quite so beautiful; while Alicante is assuming a softer red in various shades, and is more beautiful than any of them. To those who have this happy state of things I can now offer further advice, and tell them how if their fruit is well coloured, which can scarcely be doubtful, they may reasonably expect to keep their Hamburghs iu good condition till the middle of January, Muscats a month later, Alicantes and other thick-skinned Grapes till the Straw-

berries ripen.

The month of November is undoubtedly the most critical time, and I am afraid that this season it will be more than ever so, owing to the immature state of the Vines in many places. Fruit may be coloured, and even tolerably sweet, but if the Vines are not matured to a certain extent it is hopeless to expect the fruit to keep for any length of time, because, however perfect it may be to look at, it is not really so. The gross young growth of the fresh leaves and shoots suit admir-ably while the flowers are expanding and the young fruit swelling; but when the fruit is nearly fully grown a gradual change comes over the whole system. The supply the fruit requires is not so large, and it also differs somewhat from that required in the earlier stages; the hardened stem and the partially ripened leaves appear in the natural course of things, and we could not doubt for a moment that they are essential to the proper ripening of the fruit. In practice we have it conclusively proved that they are so. Who is there can say that Grapes ripened in spring by highly artificial means, when the foliage refuses with all our skill to put on anything like autumnal colouring, are equal in flavour to autumn-ripened fruit in an ordinary season? It is not so with all fruits. I could name Strawberries which are improved by forcing, are better in April than in June or July; and, indeed, it may be said of Strawberries generally that the fresher the foliage the better will be the flavour of the fruit, provided it has a sufficiency of air and light. Melons, too, notwithstanding the too prevalent practice of keeping them dry when they are ripening, produce and ripen fruit of the best quality while they are growing rather vigorously and have abundance of water. Hardened stems and ripening leaves, then, are not essential for these and some other fruits, but to produce Grapes which shall be perfect in every respect I maintain that they are absolutely so. There would be no difficulty at the present moment in finding Hamburgh Grapes produced by Vines which came a few years back from the same stock, but which, owing to some difference in their treatment, might be taken by good judges to be distinct varieties. Many people have no idea what a difference in quality the different systems of cultivation produce even amongst acknowledged good growers.

I have said that the month of November is the most critical [and although useful and cheap it does not work so freely nor time for keeping Grapes, and I will endeavour to show that the difficulties are often made greater by some widespread erroneous notions about the action of moisture on the fruit. It may be said generally that moisture will not harm the fruit if it is not allowed to condense on it, or the atmosphere allowed to become stagnant. In practice in the southern counties we cannot keep ripe Grapes safely under a temperature of 50° at this time of the year whether they are cut or are on the Vines, because we are liable at any time, even if the night is frosty, to have a change before daylight to a natural temperature even considerably higher than that, and then if the truit had been allowed to become cold the external warm air would find its way in, and the moisture it contains would immediately condense on the berries, and we know what follows. I do not consider a dry atmosphere essential to the keeping of ripe Grapes. Growing plants need not injure them, and, above all, the Vines should on no account be stinted with water at such a time or any other; only guard against condensation by common-sense firing and airing and all will be well.

When the foliage is partly ripened the Grapes generally may be more economically kept by cutting them with as much stem as possible and placing the stems in bottles of water in the way so often described in this Journal. They must be placed in the water as quickly as possible, and be suspended in a room where they can have ventilation and the temperature with a northern aspect is the best, as it will be more likely to be the least variable in temperature. Where a bunch has not sufficient stem behind it to allow of its being stuck in the water the reverse end may be used for the same purpose, and I think from present experience with like results. It is not necessary to retain any of the foliage on the stems which are cut with the bunches, nor to place anything besides pure water in the vessels for holding them.—WM. TAYLOR.

SHOWY INDIAN CRESS.

On several occasions in our Journal the merits of Tropseolum speciosum have been described, and why so charming a plant is not more generally cultivated it is not easy to understand. The following method of cultivation I have adopted with success. Choose an east or west aspect, then remove the old soil 1 foot deep and 1 foot wide. If the situation is not naturally well drained place 2 inches of rough drainage on the bottom, then fill up with peat or any rich light soil. Plant the roots about If oot apart, 3 inches deep, and 3 inches away from the wall; placing a small quantity of silver sand round each set, and be careful that the soil is kept moist by frequent sprinklings from the rose of a waterpot or syringe. When the shoots appear above ground they are very liable to be destroyed by slugs. The first year I was rewarded by a vigorous growth and a few flowers. I feared the plants would suffer last when they stood estaly without the least protection. but they stood safely without the least protection. They have made sturdy progress through the past unfavourable summer, having rewarded me with a grand display of their charming flowers; but the frosts early in October injured them.—NORTH YORK.

MATERIALS FOR BUDDING.—The material alluded to by "D., Deal," in his "French Notes," at page 312 of the Journal as "rushes," and which is inquired after by one of your correspondents, is probably the split triangular leaves of Spar-ganium ramosum, which I have seen used both in France and Jersey, and where the material finds some favour, frequently on the score of economy. The leaves cut from the ditches are gradually dried and afterwards split longitudinally, drawn tightly through the fingers, and tied in bundles ready for use. I have tried the material and find it works freely and is sufficiently strong, but was unaware of its not requiring to be removed after the buds had taken. So long, however, as good stout soft cotton can be purchased at about 1s. ld. per pound I shall continue to use it, as it is strong, does not give, and possesses important time and labour-saving advantages during the budding season, which is frequently too contracted, the cotton from its substance and width requiring but few twists or wraps in tying; about four turns, two above and two below the eye, usually being sufficient to cover and secure an ordinary bud. Do any of your correspondents know of a better material and which can be obtained largely and cheaply? A soft jute packing string has been tried here (the Experimental Garden),

lie so close as the cotton; it also gives slightly. The late budding season has certainly not been a contracted one, for although the work in many places from want of ripe buds could not be commenced before the first week in August, it has been continued up to the commencement of October, and here buds have been successfully inserted up to the 9th of that month, and rarely has the bark continued to run so well.— T. LAXTON, Bedford.

THE ROSE ELECTION.

MRS. PARTINGTON says, "Comparisons are odorous," and doubtless in the matter of Roses they are much more odorous than the old lady herself meant when she uttered the sentiment. Anyway they are certainly of interest, and sometimes very useful. Early, then, in this election I wrote to Mr. Ellwanger of Rochester, New York, for his opinion of the Roses of recent introduction as regards exhibition qualities, and also for the best garden varieties. Whether or not the idea of the election suggested to Mr. Ellwanger the propriety of enlarging on his views I know not, but on both these topics he has embodied his ideas in the form of interesting papers—of which he was kind enough to send me copies—from which I shall make a few extracts. First, however, let us compare the result of our election of the newer varieties side by side with Mr. Ellwanger's list.

English Election.

1. Capitaine Christy
(Duchesse Vallombrosa
(Star of Waltham
4. Mons. E. Y. Teas

4. Mons. R. Y. Teas
5. A. K. Williams
6. Abel Carrière

32. Rev. J. B. M. Camm 33. Oxonian 4. Firebrand 35. Madame Lacharme 36. Triomphe de France

Now in comparing the two lists the point that strikes one is that in the English list only two Tea Roses are named, whilst the American list contains eight. This always appears to me to argue that the climate of the Tea list is more favourable to the cultivation of that class. Teas are beautiful-extra beautiful in favourable situations, and extra valuable in an exhibition point of view from their lasting qualities; but how few can grow them! and when I state that in the 148 Roses named only twenty-one Teas are mentioned by the twenty-four electors it will, I think, be felt that our English climate is not the most beneficial to the more delicate and tender specimens of that

Mr. Ellwanger adds a note that Marguerite Brassac, Mons. E. Y. Teas, and La Rosière are very similar to Charles Lefebyre, Sénateur Vaisse, and Prince Camille de Rohan. Of the first and third there is little doubt; I am not aware that Mons. E. Y. Teas had been charged with copying before. In his summing-up Mr. Ellwanger also notes the great advance of our English growers, and says, leaving out the Teas and Noisettes, honours are divided between the English and French, each claiming thirteen Roses; but he also adds that "the English Roses come from a few sources, while in France there are very many engaged in the production of seedling Roses."

It is only necessary for me to add that the New York list is placed in order of merit, but that in the attached notes marked

praise is awarded to Cheshunt Hybrid as "not only beautiful but a new type; and a new type among Rosss, if good, is what

we are always ready and anxious to see."

In concluding the election of the newer exhibition varieties it is only necessary to add that the electors were twelve amateurs and twelve nurserymen, and the names of the electors are as and twelve nurserymen, and the names of the electors are as follows:—*Rev. C. H. Bulmer, Credenhill, Hereford; *Mr. John Scott, Warminster; *Mr. J. Tranter, Upper Assenden, Henley-on-Thames; *Rev. E. N. Pochin, Barkby Vicarage, Leicester; *Mr. E. Claxton, Ash Villa, Green Lane, Wavertree, Liverpool; *Miss Penrice, Wilton House, Norwich; *Mr. W. Farren, How House, Cambridge; Mr. A. G. Soames, Irnham Rark, Bourne, Lincolnshire; *Mr. T. Gravely, Cowfield, Sussex; *Mr. J. Brayer, enclosed A. J. Wetseley, E. G. Grett Boods. *Mr. J. Brown, gardener to A. J. Waterlow, Esq., Great Doods, Reigate: Mr. W. L. Palfrey, Millington, Altrincham; *Mr. G. Baker, Holmfels, Reigate. *Messrs. Mitchell & Sons, Piltdown, Gokfield; *Mr. Henry May, Bedale, Yorkshire; *Mr. William Rumsey, Joyning's Nursery, Waltham Cross; *Messrs. Bunyard & Sons, Maidstone; *Mr. G. Prince, Oxford; *Messrs. Kinment & Kidd, Canterbury; *Messrs. Paul & Son, Cheshunt; Messrs. Ewing & Co., Norwich; *Mr. G. Davison, Hereford; *Mr. G. W. Piper, Uckfield; *Messrs. R. Mack & Son, Catterick Bridge; Mr. Cranston, Hereford.

Those with asterisks prefixed to their names were also voters in the garden election, together with the following cultivators of Roses:—Mr. W. Hand, 10, Marsh Street, Newcastle, Staffordshire; Mr. A. Evans, Marston, near Oxford; Rev. H. H. Dombrain, Westwell Vicarage, Ashford, Kent; Mr. R. W. Beachey, Fluders, Kingskerswell, Devon; Rev. H. Biron, Harbledon, Canterbury; Mr. S. McMaster, gardener, Bankfields, Easthorn, near Birkenhead; Mr. Joseph Hinton, Warminster; Mr. T. B. Haywood, Woodhatch, Reigate; Rev. J. M. Fuller, The Vicarage, Bexley, Kent; J. H. Pemberton, Esq., Havering-atte-Bower, near Romford; Rev. W. F. Radclyffe, Okeford Fitzpaine; Mr. W. H. Wakely, Rainham, Kent; Mr. J. Brown, Longfield,

Heaton Mersey, near Manchester.

Mr. Cranston, Hereford, and Messrs. Ewing & Co., Norwich, also contributed to the garden election, and as their lists contain many Roses that are not exhibition varieties they may be usefully published.

Mr. Cranston's selection.

To all who have assisted my grateful thanks are due.—JOSEPH HINTON, Warminster.

P.S.—I propose next week to compare the American garden varieties list with our own.-J. H.

NOTES FROM THE NORTH—FORGLEN HOUSE.

A VERY fine specimen of Cycas revoluta has flowered this season in the temperate house at Forglen House, Banffshire, the residence of Sir R. T. Abercromby, Bart. Twelve years ago the writer recollects shifting this fine plant into a 6-inch pot; it was then about 15 inches wide, and had a crown about the size of a Boman Hyacinth. To-day it measures from the top of the tub 4 feet 9 inches high, 8 feet 6 inches spread of crown; the trunk is 2 feet 7 inches in height and 3 feet

6 inches in girth, with nine courses of leaves. The plant has a very handsome appearance, and bears testimony to the who has been entrusted with the superintendence of this fire. place and its valuable collection of plants (probably the most complete in the north of Scotland) for well nigh twenty years. The backward season has told beavily against outdoor gross here as elsewhere. Wall fruit, with the exception of Cherries, will not ripen. Small fruits have been very abundant, but are a month or five weeks later than usual.

In the vineries heavy crops are the rule, yet a monster bunch here and there is to be seen one of which (I forget the variety), measured 18 inches across the shoulder and the same in length, with good colour, and likely to finish well. The Peach trees are also heavily cropped, and the fruit is of first quality. In the orchard house heavy crops are ripening off. Melons and Cucumbers are grown in neat low span-rough houses, such as some gardeners I know would envy. The crops are excellent, Melons being specially fine. The flower garden is extensive, and requires many thousands of plants to be mised yearly for its adornment. Violas do well here, and are grown in large numbers. There is a fine collection of Roses which do very well. Altogether this is one of the very finest places in the county, and gives evidence in every nook and corner of much care and forethought in its management.—TRAVELLER

STRAWBERRY CULTURE IN POTS FROM NOVEMBER TO MAY.

IT may be remarked that some of the earliest-forced plants of last spring are fruiting well now, and that the autumn fruiting of Strawberries in pots is a much simpler matter than some believe. Most Strawberry plants for winter and spring forcing will yet be standing in the open air. The season has been very unfavourable to their growth, and now the weather is much against the plants becoming thoroughly matured. Altogether no great results should be expected from Strawberries in the spring of 1880. Still Strawberry plants may be considerably improved during the next three weeks.

The best way to assist plants at the present time is to stand them out in a fully exposed position; keep the soil in the pots free from weeds and decayed leaves, and pinch off all runners as soon as they appear. Liquid manure, which may not present time in the present time in the present time in the present time is to stand them. viously have been liberally applied, should now be given at every other watering, and at the same time never allow them to suffer through deficient supplies of water. Drying off Strawberry plants in pots may be a successful practice with some, but keeping them constantly wet is at least an equally successful way of treating them, and in our opinion the most advantageous. Dryness at the root always causes many of the young fibres to wither and die. Our main points of culture so tur may again be repeated: Expose the plants as much as possible to the sun to mature the crowns. Avoid placing them under glass or any other protection until they are removed to their forcing quarters; and during the whole time they are in pots, while resting or growing, always keep the soil moist.

Respecting forcing, few begin this operation until December, but their requirements then are just the same as in the following months, only the earlier in the season forcing is commenced the more difficult it is to accomplish. However, whether in December, January, or any other month, the plants must not be placed in too great a heat at first; 60° or 65° by day and 50° by night is sufficient to start them robustly. Some cultivators plungs the pots in a slight bottom heat to start the plants into growth. We never do so, but rather try to avoid it, as this, like placing them under glass in autumn, must be followed up if it is wished to avoid giving them a check. When the plants are placed in the above temperatures in December, January, or February little signs of starting into growth will be visible for a considerable time, but they must be well watered during this time. As soon as the flowers are visible the temperature may be raised 5°.

Any kind of house where heat can be had to the extent named will do for their culture. Special Strawberry houses are the exception, not the rule. We force some of our plants in a Pine house, others in plant pits or early vineries always, however, preferring the house, where red spider will do lesst harm, as Strawberries are rather subject to these pests. Clear water should only be used until the flower buds appear, then give liquid manure at every other watering. A moist atmesphere will assist the plants considerably in growth, but during the time they are in bloom a rather dry air suits the setting or

with a feather to insure the fruits setting well.

When each plant is bearing three or more dozen fruits about the size of small peas the smallest and worst formed may be clipped out, leaving from twelve to twenty of the best to form the crop. The time required from when the plants were placed in heat until the fruit is ripe depends entirely on the state the plants were in before forcing was commenced, the heat that ras applied to them, and the weather. Well-matered plants and plenty of sunshine produce fruit rapidly. A number of plants placed in heat every three weeks will keep up a good succession of fruit according to demand .- A KITCHER GARDENER.

VINES IN POTS-STOCKS-GOLDEN QUEEN.

It is very gratifying to me to find that, with one notable exception, my practice given under this heading on page 283 is approved of by such an able and experienced grower as Mr. Gilbert undoubtedly is. He, however, does not agree with me in following what I am inclined to think a very important detail-vis., planting out the Vines in prepared pits in preference to fruiting them in pots. One trial only seemed to convince him of this practice being unsatisfactory; but I think that should he again give the plan a trial, looking as closely after the watering as he undoubtedly does those he fruits in pots, the result will be much more satisfactory.

Assistants as a rule are apt to be negligent in the matter of watering borders; in fact this should not be left to their judgment, however enthrusiastic and paintaking they may be. I

do not say deficiency of water was the positive cause of failure, but very probably it was.

If Mr. Gilbert has not already grown Pearson's Golden Queen in his succession pot where, I strongly advise him to try it in good numbers. I have found it to answer remarkably well grown to succeed the earlier varieties. Both the colour and flavour is improved under this treatment. Black Alicante and flavour is improved under this treatment. Diack Alicante forms a capital companion for it, and this, too, is improved in flavour by the treatment. The one weak point in Black Alicante is its want of quality, and for this reason it is but little grown in many good gardens. To have it in perfection it should either be grown with the Muscats or receive similar treatment. Both the Alicante and other late varieties may ripen, or rather colour well, in a house without fire heat prowiding they are started early. But the question is, Will they be fit for the table? I think not, especially this season, as neither Black Hamburgh nor Foster's Seedling are good, although to all appearances quite ripe, being in reality very poor and watery. This is not the only drawback, as from the fact of saccharine matter being almost absent they will keep badly.

"A KITCHEN GANDENER" on page 304, after stating that Black Alicante is altogether a failure under cool treatment, mentions that he has lately inarched Golden Queen on all of them, and "expects better results." I hope he will not be disappointed, but I very much question if he will not. I saw the Golden Queen at Mr. Pearson's, Chilwell Nurseries, before it was distributed. It was fruiting with a number of other seedlings, all of which were the result, if I remember rightly, of a cross between the Black Alicante and Ferdinand de Lesseps. It resembles the former in the shape of bunch and berry, and the latter in colour and vigour, its flavour being a compound between the two; consequently it is a stronger grower than the Black Alicante, and is also somewhat, though not much, earlier. If I grafted or inarched on either of its parents it would be the Ferdinand de Lesseps. To have it, however, good in a cool house it should have for a stock a good early variety, none being more suitable than Foster's Seedling. The best bunches I have yet seen of it were grown on this stock by Mr. Atkins of Lockinge, who, it will be remembered, secured the valuable first prize offered in 1878 by the raisers. Golden Queen when well grown is a very handsome and desirable variety, but badly grown it is a poor colourless Grape, giving pleasure to no one.-W. IGGULDEN.

NATIONAL ROSE SOCIETY-SPECIAL PRIZES.-I am happy to announce that those generous lovers of the Rose, Mr. J. and Mr. T. Hollingworth of Turkey Court, Maidstone, offer the following prizes to be competed for at the National Rose Society's Exhibition at the Crystal Palace:—John Hollingworth, Esq., a cup, value ten guineas, for the best stand in seventy-twos,

forming of the fruit. In our weather when but little air can | for numerymen; and T. Hollingworth, Esq., a cup, value six be admitted it is a good plan to rub the flowers gently over guineas, for the best eighteen Teas and Noisettes, also for nurserymen.-D., Deal.

SHEFFIELD GARDENS AND GARDENERS .-- No. 4.

FROM another central point—the Botanic Gardens—nearer the town and less breezy than the district previously referred, some very good examples of gardening are easily reached. One or two of these may be briefly noticed; but it may be appropriate first to glance at the

BOTANIO GARDINIS.

These are about eighteen acres in extent, and contain some fine ranges of glass. The conservatories, which are spacious structures, have a central and two end domes, and as viewed from the terrace walk the effect is rather imposing, the length of the range being 340 feet. The partition is 120 feet long, and there is a range of houses still longer for preparing plants for the comservatory and flower garden, and a few other structures devoted to plant culture. The grounds contain a vary good assortment of trees and shrubs and an old-fashioned rosery; but the chief feature of interest is the principal glass range. Under the first deme is a fine tree of Acacia affinis, the spreading limbs of which occupy much space—it is quite a timber tree; then a long compartment is devoted to Palms, Tree Ferns, &c., amongst which are fine masses of Woodwardia radicans. Over the pathway traversing the front of the range there are at intervals arches of such old Fuebeles as serratifelia, corallina, gracilis, Riccartoni, &c., very old plants, or trees, ladem with elegant flowers, which are seen to great advantage. The space beneath the central deme is occupied with grand Palms, Phomiz dectylifers and P. farintiers being of great size and in superb condition. A remarkable Indiarabber Tree, Ficus indica, attracts attention by the roots that have issued from the stem some 20 feet above the ground, which they have long since reached and entered, and now resemble large props supporting the specimen. These Palms, &c., were planted out by the present Curator—Mr. Ewing—some years ago, and it is evident they have received the best attention throughout their career. A long division of flowering plants leads to the other domed division, the centre of which is occupied by a tank devoted to the culture of the Victoria regia. The plant flourishes well liers, producing noble leaves and flowers, and the structure is rendered additionally ornamental by specimen Palms and other fine-foliaged plants elevated at intervals above the surface of the water. In the several structures lighted the chief range is a diversified collection of plants—Filmy Ferns, well grown, Ameschochili, the newer Crotwns, Colemans, Dracenas, &c., with many other plants that are old, and rase rather than new, for all are cherished by Mr. Ewing, who appears to combine the ancient with the modern, and thus renders the gardens interesting and instructive as well as attractive. In the grounds carpet bedding is well carried out for the gratification of the visitors, and the entire establishment is conducted with the skill and sound judgment that the Carator is so well able to exercise. That his services are appreciated, and justly so, is evident by the fact that after a term of twentyone years additional means are being provided to and him in his work, and something more substantial than official and public approbation is being granted him for the duties he has so long, well, and faithfully performed. The pleasure of a visit to the gardens is considerably enhanced by the gardanty and courtesy of Mr. Ewing, who is highly esteemed by all who

OAKHOLMB.

Almost close to the Botanic Gardens is this, the residence of T. Wilson, Esq., and nowhere about Sheffield are plants more skilfully grown than they are here by Mr. Hannah. of the specimens are worthy of a place at the best exhibitions in the hingdom, and all are in the highest possible condition. There is a very fine range of glass, the houses being light and spacious, with ridge-and-furrow roofs. The five-foliage plants are in superb condition. Croton irregulare as it is continuently seen is not particularly attractive, but to see it as 10 is an Osk-holme, 5 feet high and 4 through, and without a failing point, it cannot fail to command approbation. C. pictum is much larger, yet equally well furnished and finely coloured—one of the finest plants of a really good Croton to be seen in the country. Some of the other older forms, such as C. variegatum, are in splendid condition; while many of the newer sorts, though necessarily smaller, are in the same excellent health and colour.

In admirable contrast are stately examples of Sphærogyne speciosa and Cyanophyllum magnificum, plants that are not so often seen in their best condition as they ought to be. Dracænas are also well grown; and especially noticeable on the side stages are some admirably grown Sonerilas. The beautiful Begonia imperialis, with its plush velvet-like foliage, is rarely seen so fresh and good as here, and few dwarf-growing ornamental-foliaged plants are better worth growing. A collection of Orchids is being established, Vines having been removed from one of the divisions to make room for the plants, which were looking extremely well, the Calanthes being very attractive. One of the houses is devoted to Ferns and Selaginellas, and as grown in a natural manner on rocky mounds and interspersed with Begonias and other suitable plants a charming effect was produced. The health and cleanliness of all the plants and the neatness of the houses were remarkable. The grounds outside—the spacious lawns—appeared equally well cared for, and afforded abundant testimony of the industry and ability of the gardener. Mr. Hannah was a pupil of Mr. Ewing, and is a credit to him and a worthy example of Sheffield gardeners.

ASHGROVE. Only a few minutes' walk from Oakholme is this the residence of C. H. Stone, Esq., a gentleman who is evidently a great admirer of plants and a liberal purchaser of what is good amongst them. This garden is small, but is almost filled with well-constructed and light houses, and these houses are filled with well-selected plants. These are not large, as they are mostly in a young state, but are in capital condition, Mr. Fellows being apparently no novice in plant culture. In beautiful condition was Rhododendron Princess Royal, one of Messrs. Veitch's hybrids of the R. jasminiflorum type—Per-petual-flowering Rhododendrons I have heard them called, and the name is appropriate, for they appear to flower at all periods of the year, and in the different varieties are extremely attractive, and will be certain to become highly popular for various decorative purposes. Several of the newer Crotons and Dracemas of Messrs. Veitch, Williams, and Wills are being established, and Messrs. Veitch's striking Alocasias Veitchii and Warroqueanum are in a most promising state. Orchids are represented by several healthy specimens, and the newest varieties of Dr. Denny's and Mr. Pearson's Zonal Pelargoniums are included in the collection. Camellias and Azaless, with Rhododendron ciliatum, are in as good health as can be desired, and red and white Lapagerias are making excellent growth and producing their beautiful flowers freely. The object of Mr. Stone appears to be to have plants that are really good, and his gardener's pleasure, as well as duty, appears to be to grow them well : hence the satisfactory condition of the collection in this small but enjoyable garden.-J. W.

GLAZING WITHOUT TOP PUTTY.

This system of glasing is not adopted so generally as I believe it deserves. One trial, I am confident, will convince anyone of its superiority provided certain conditions are carefully attended to. Repairs will be less, the appearance is very little affected, and the house will prove more durable than when top putty is used.

My employer has recently erected a range of houses nearly 200 feet in length, and, except for the upright portions, top putty has been entirely dispensed with. The past season has given ample opportunity of testing the resistance of the system whole has proved to be thoroughly watertight. The wood having been well painted twice, special care was taken to place the bottom putty in regular layers, using it liberally and of the best quality, pressing the glass down very firmly upon it, and secured with four small sprigs driven into the sashbars, two at the lower end of each square, and two midway between top and bottom. The paint over this was allowed to cover fully an equal breadth of glass on the top as that resting on the rebates below. There being so little putty exposed water cannot find a lodgment in the numerous small crevices which are too often to be found when top putty is used; and however minute they may be water is certain to get in, but does not quickly evaporate, and so for a long time the wood will be almost continually wet, causing it to decay and the putty to peel off.

In support of the above I may mention a house in this locality (built with several others some nine or ten years since), that was glazed without top putty. This house at the

present time is in a better state of preservation, has cost less for repairs, and throughout continued more efficient than those glazed in the ordinary way.—C. MAXTED.

THE ROSE SEASON OF 1879—A RETROSPECT.

NEVER, perhaps, since the Rose became so generally grown and so continuously exhibited has such a season as the past been experienced. Growers, exhibitors, managers of Rose shows, and judges have all been puzzled and at their wit's end. Growers, for they have seen wet and wind, frost and cold, injuring their plants, and well nigh taking all the pleasure out of their garden; exhibitors, for they have not known when to calculate on their flowers being ready, or to preserve them in any degree of freshness when they were so; managers, forthey have had to shift and change the days of exhibition, some even twice, and ultimately no better off for doing so; judges, for Roses have been so utterly out of character, and in the great majority of cases so indifferent, that it has not been an easy matter for them, it being far more difficult to judge bad and

indifferent stands than good ones.

In such a season, therefore, one's retrospect must be of a very different character to what it has usually been; and although I have, either in my capacity as Hon. Sec. of the National Rose Society or as Judge, attended a goodly number of Rose shows, and have only been hindered from attending more from the fact that I could not be in two places at once; yet whether it has been north or south, east or west, there has been something to disappoint one in most of them. As, however, I have recorded my impressions of the various exhibitions at which I have been present in former numbers of the Journal I shall not enter into any of these details again, but endeavour to draw a few conclusions from a general survey of the field. Now that the smoke has cleared away and the combatants have returned to winter quarters one is better able to judge of results

than when we were in the thick of the fray.

I think one most gratifying result has been the increased and increasing influence of the National Rose Society. During the past season I have been called on to assist by advice and counsel in the formation of these Rose societies avowedly on its lines, and in each case a great deal of enthusiasm was shown and a substantial success achieved notwithstanding the adverse circumstances of the season. The rules for judging issued by the Society have been taken as the standard authority on the subject, while the "Hints on Rose-Growing," which have been widely distributed, have been much appreciated. The Society itself has now become established on what we may hope is a firm basis. The unfavourable season relieved somewhat of the pressure on its funds and it is now entirely free of debt, while the zeal displayed on its behalf is evidently increasing. The special prizes already announced and those referred to in another column strongly evidence this; and I may, without egotism I hope, refer to another proof—the honourable reception given to me as one of its Hon. Secretaries at Brie-Comte-Robert and my election as President of the Jury, both of which were due to this and not to any personal feeling, as I was unknown to most of the members. It was simply a tribute to the high position attained by the National Society in the estimation of foreign Rose-growers.

The increasing interest in the Rose itself, the extension of its growth and exhibition, have also come clearly out in the past season. No adverse circumstances seem to be able to damp this. Growers for sale multiply, old-established firms increase their Rose grounds, and to the satisfaction of the amateur prices come down. Many new hands are to be found in our lists of exhibitors, while the older ones still put forth their energies to maintain the position they have already won; and although there must have been very bitter disappointment to a great many exhibitors through the backwardness of the season, yet it is pleasant to find that those who have suffered most are amongst the most eager to show their determination not to give in. We may certainly say that no flower has been able to attract to itself alone so large and enthusiastic a number of admirers as that which is deservedly called the

queen of flowers.

There can be no good gained by disguising the fact that Rose exhibitions this year have been disappointing. In other seasons we have been able to look back on some special stands on which we can allege the seasons are special stands on the seasons which we can allege the seasons are seasons as the seasons are seasons are seasons as the seasons are seasons are seasons as the seasons are seasons as the seasons are seasons are seasons as the seasons are seaso which we can dwell with pleasure as something super-excellent -a box of Teas, a stand of twenty-four or twelve of some especial Rose; but in this season my memory at least dwells upon nothing of this character. I did not see at Norwich Mr.

Baker's stand of forty-eight which so excited the wonder and admiration of Mr. D. T. Fish; but the only stand which dwells in my memory as of superexcellent character was one shown, not at a Rose show, but at Taunton on August 14th by Mr. George Prince of Oxford. It was a box of forty-eight, and a better one it has never been my lot to see. All who saw it will remember, however, with admiration the wonderful bloom of Niphetos shown by Mr. Jowitt of Hereford at the National exhibition at the Crystal Palace; it was a veritable roc's egg in size, and as pure in its white as it was possible for a Rose to be.

The season, so indifferent in every respect, of course was unfavourable for the production of new Roses, and never have I seen so few brought forward. Of the much-spoken-of Stapleford Roses I do not remember to have seen any exhibited except one small bloom of Duke of Connaught. It is satisfactory to find that English-raised Roses—not Roses bought in France and christened and sent out in England, but really English-raised Roses—have been so successful. Some of the best blooms of new Roses that I can call to mind are of this Mrs. Laxton, Duchess of Bedford, and Harrison Weir will fully maintain the character of their raisers. There are other good ones, but I am only recording those which I have seen in exhibition stands. Not one of the Roses sent out in France last autumn has made anything like a sensation, indeed I hardly recollect seeing one at which one would come to look twice; but there is one of the forthcoming English Roses, which will be, I doubt not, a great favourite—Messra. Paul & Son's Duke of Teck, a brilliant scarlet flower in the style of Duke of Edinburgh. I saw it exhibited at Reigate, when it struck me as the most dazzling flower I had ever seen, and this in a season when so many of our brightest flowers were shaded. It is a Rose of very great promise. Madame Lambard and Madame Nabonnand of the previous year have been shown well, and the former especially promises to be a valuable addition to this beautiful class.

Questions have arisen which will call for a solution in some form or other—the "too much alike Roses," the placing of Cheshunt Hybrid and other similar Roses amongst Teas. They have been largely discussed at our exhibitions, the National Society has been urged to take action on them and settle the points, and perhaps ere long it may do so. We are drawing to the close of this most unpropitious year. Rosarians are busy arranging their beds and planting for another season. They may do so hopefully, I should think, for certainly they cannot expect to see such another season as this. Well, the fine autumn weather now experienced in many places must be favourable. May they all draw prizes and no blanks, and next season have a different tale to tell from this.—D., Deal.

PEARS AND PEACHES.

SUMMER Beurré d'Aremberg proves to be a valuable addition to our autumn Pears, and well sustains the high character given it in the last edition of the "Fruit Manual." vigorous young tree of it, an oblique cordon, which bore some fruit this year for the first time. It was not ripe till the second week in October, but that was owing to the dull cold summer, all fruit being from three weeks to a month later in ripening than usual. "Flesh yellowish, very buttery, tender, melting, and very juicy, sweet, richly flavoured, and with a musky aroma," says the "Fruit Manual." True every word of it, say I; and gladly add that even in this year of undersized fruit it proves to be of medium rather than a small size.

"The best feature in the garden," said my friend Mr. Wright as we were looking at the Pear wall a few weeks ago. The wall runs north and south, has palmette verriers on the west side all of them just coming into full bearing; and oblique cordons, comprising a selection of sixty to seventy varieties, on the east side. Several of the cordons have reached the top of the wall, all are forming fruiting spurs, and so many are in bearing that they will afford some three hundred fruits for the desert this season. The palmette verriers bear bushels of fruits—the cordons a few dozens, which are really more useful than the bushels, serving as they do to maintain a constant and varied supply of really choice fruit for table. Who would be without some cordons? Who need be without some? They are planted 18 inches apart, have a single stem, are trained to an angle of 45°, and answer equally well on a low wall or a lofty building.

everal inquiries we have had lately about suitable varieties of Peaches and Nectarines for culture under glass tend to show the prevalence of an erroneous impression that all of them

will not answer under glass. Experience shows that every kind of known excellence in the open air proves equally good in a Peach house; the only most point in the matter being this—Are those varieties which fail to ripen fruit in the open air worthy of space under glass?—EDWARD LUCKHURST.

ECLIPSE CAULIFLOWER.

MR. BARDNEY, in describing the above as "a very useful wariety," has hardly given sufficient praise to it. I can speak in the highest terms of it. I have submitted for your opinion four heads, and as to the variety producing but "few leaves," I cannot quite agree with Mr. Bardney. My experience of it both last year and this is, that it is sufficiently self-protecting till the heads are too large for the parlour table; but leaving all differences of opinion out of the question, so far as I have seen of it, it is the best Cauliflower for late summer and autumn use in cultivation. I grow it extensively, but it is now nearly over with me, and is succeeded by late-sown Early London Cauliflower, followed by Veitch's Autumn Protecting Broccoli, which is equally good in its season as the Eclipse Cauliflower.—JOHN GADD, Thorndon Hall.

[The Cauliflowers sent were extremely fine, the large heads being white, close, and solid; and the smaller, about 3 inches in diameter, being quite hidden among the mass of surrounding leaves.—EDS.]

FRUIT SHOW AT HEREFORD.

OCTOBER 29TH AND 80TH.

UNDER the auspices of the Pomona Committee of the Woolhope Club by far the greatest Exhibition of Apples and Pears of the year was held on the above dates in the Museum and Woolhope rooms, which were crowded to their utmost capacity by the contributions of cultivators in Herefordshire, Gloucestershire, Berktributions of cultivators in Herefordshire, Choucestershire, Berkshire, Worcestershire, and Kent, together with an extensive and interesting display from France. As was inevitable after such a cold, wet, and sunless season the fruit was generally small, yet notwithstanding there were many splendid dishes exhibited, notably by Mr. Hayoock and Mr. Lewis Killick from Kent, and Sir Henry Scudamore Stanhope, the leading exhibitor of Herefordshire, while the French fruit was remarkable for its fine size and colour.

The superiority of the Kentish fruit both in size and colour over that of the local examples was very manifest. The climate of Kent is more genial than that of Herefordshire, and to this fact Mr. Haycock's fruit was attributed; but the result is due to something more than climate—namely to young trees and superior culture. If the same skilled attention were bestowed on young trees in Herefordshire as is apparent at Barham Court, the splential of the form of the court of the same skilled attention were bestowed on young trees in Herefordshire as is apparent at Barham Court, the splential of the form of the court of the did soil of the famous cider county would in a great degree comdid soil of the famous cider county would in a great degree com-pensate for slight climatic disadvantages. So far as we have seen not nearly the amount of cultural care is given to the producing of superior specimens in Herefordshire that is exercised in Kent; and the products of the first-named county are chiefly the results of not special but ordinary cultivation. The achievements of Herefordshire growers are great, but they would be greater from an exhibition point of view if young trees were planted more freely in selected positions, and special attention given to the several cultural details that contribute so powerfully to the suc-cess of those who adopt them. Yet after all climate told its tale at the Show under notice, for while the Kentish was superior to at the Show under notice, for while the Kentish was superior to the locally grown fruit, the former was in turn excelled by the examples from "sunny France," but in that case we doubt not that special care and superior culture had been largely exercised

in producing the specimens.

The competition was arranged in five divisions, the first being The competition was arranged in five divisions, the first being devoted to professional men (nurserymen or market gardeners), in which prizes were given for dessert or culinary Apples and Pears; the second to amateurs, which was subdivided into five classes; the third was a free division, being, as the schedule comprehensively put it, "open to all and from anywhere;" the fourth was devoted to vintage or cider and perry fruit, there being nine classes; and the fifth division was devoted to cottagers, the condition being that their rental should not exceed £7 per annum, and they were to be recommended by a subscriber a member of the tion being that their rental should not exceed 2. per annum, and they were to be recommended by a subscriber, a member of the Woolhope Club, the clergyman of the parish, or their employers. Altogether (excluding the cottagers' division, which did not fill), there were thirty-eight classes, which comprised the staging of nearly two thousand plates of fruit.

nearly two thousand plates of fruit.

The professional class did not evoke a very extensive competition, the competitors being Mr. Lewis Killick, Maidstone; Mr. Griffiths, Tillington Nurseries, Hereford; Mr. Barnes, Gloucester; and Mr. Grove, Tupsley, Hereford.

The Kent producer only showed in one class—viz., that for collections of culinary Apples of not less than ten varieties, the

other exhibitor in the class being Mr. Barnes of Gloucester. The superiority of the Kent over the Gloucester fruit was very marked, superiority of the Kent over the Gloucester fruit was very marked, the Kent Apples being at least half as large again, and much clearer in the skin and purer in colour. Mr. Killick's variety included Lord Suffield (particularly fine), Lorddington Seeding or Stone's Apple, Warner's King, Bedfordshire Founding, Cox's Pomona, Lord Derby, Peaegood's Nonesuch, Tower of Glamis, and Ecklinville Seedling; while Mr. Barnes's collection included Loddington's Monstrous, Flanders Pippin, Caraway Russet, Kentish Pippin, Devoushire Quean, Broadend, &c. Mr. Griffiths of Tillington was successful in the class for dessert Apples, Mr. Barnes of Gloucester being, as in the culinary fruit, second. In the professional class for dessert Pears Mr. Barnes was first, and Mr. Grove of Tuplely second; Mr. Barnes's collection including Phelpe's Bergamot. Bishow's Thursh Nazier Viving Collection including

the professional class for dessert Pears Mr. Barnes was first, and Mr. Grove of Tupeley second; Mr. Barnes's collection including Phelps's Bergamot, Bishop's Thumb, Napoleon III., Vicar of Winkfield, Beurre Quetelet (Comte de Lamy), Duchesse d'Angeulème, Marie Louise, &c.; Mr. Grove's soflection comprising anong others Brown Beurre, Beurre de Capiaumont, Marie Louise, &c. In Classe 4, fer coninary Pears, no professional competed. Mr. Taylor, Sheretington, was placed first with Uvedale's St. Gertnast, weight 2 fbz. 12 cms.; Dr. Chapman following with Catillac, 2 bs. 6 cm, and Rev. W. H. Tweed being third with the same variety, 2 bs. 44 cms. The professional division was chiefly remarkable for Mr. Lewis Killick's splendid collection of large, finely formed, and well-coloured culinary fruit.

well-coloured culinary fruit.

well-coloured culinary fruit.

The amsteur division (for gentlemen's gardeness or gardeness who do not keep gardeness) brought out a splendid competition, the principal exhibitors being Mr. Haycouk, gardener to Mr. L. Leigh of Barham Court near Maidstone, Kent, and Sir Henry Scudamore-Stanhope, Bart., of Holme Lacy, Herefordshire. Prominent among the other exhibitors and prizewinners were Mr. Shingles, gardener to Earl Ducke; Mr. H. Higgins, Thinghill; Mr. Taylor, Sherdington Court, Cheltenham; Mr. C. Williams, gardener to Mr. Joseph Pulley, Lower Eaton, Herefordshire; and Mr. Froggatt, gardener to Major Wegg-Prosser, Belmont, Herefordshire. The feature of this part of the Show was Mr. Haycock's fruit, which secured for the exhibitor four first prizes out of five; and the collections sent by Sir Henry Scudamore-Stanhope, wite secured one first, two seconds, and a third. Mr. Haycock's fruit was, a local papersays, "really magnificent," but we have seen him stage much finer. Sir Henry Scudamore-Stanhope, one of the most competent amateur pomologists in the kingdom, was a close second, and with the other competitors admirably sustained the much finer. Bir Henry Saudamore-Stanhope, one of the most competent amateur pomologists in the kingdom, was a closs second, and with the other competitors admirably sustained the honour of the native pomona. Mr. Haycock's first-prize collection of dessert fruit comprised the Old Nonparell, White Nonparell, Duchess of Oldenburgh, Reinette Grise, Syks House Russet, Golden Pippin, Cox's Orange Pippin, Reddleatone Pippin, King of the Pippins, Hibston Pippin, Reinette de Canada, Nonparell, and Lady Derby. Sir Henry Stanhope's Apples included Court Pendu Plat, King of the Pippins, Mother, Winter Pomeroy, Golden Reinette, Margil, Kibston Pippin, Duke of Devonshire, Reinette de Canada, Pomeroy, Cornish Gilliflower, and Claygate Pearmain. In the class for not less than six varieties of culinary Apples Mr. Haycock was first again, the varieties being Reinette de Canada, Bedfordshire Foundling, Lord Suffield, Small's Admirable, Calville Blanche, Dumelow's Seedling, Washington, Belle Joséphine, Hawthornden, Belle Dubois (Gloria Mundt), Northern Greening, and Emperor Alexander. Mr. Higgins was second with a very meritorious collection, comprising Blenheim Pippin, Wasner's King, Dumelow's Seedling, Alfriston, Emperor' Alexander, and Lord Snffield. Sir H. Stanhope (third) had in his collection Cox's Pomona, Dumelow's Seedling, Emperor Alexander, Lord Snffield, Ecklinville Seedling, Gloris Mundi, Mère de Ménage, Warner's King, Bedfordshire Foundling, Tower of Glamis, Blenheim Orange, and Striped Beefing.

Of Pears in the amateur division Mr. Haycock secured first honours for dessert fruit with Doyenné Bouscoch, Marie Benroist, Beurré Hardy, Pitmaston Duchesse, Duchesse d'Angoulème, Gansel's Bergamot, Althorp Orasanne, Beurré Clairgeau, Doyenné Boussoch, General Todtleben, Beurré de Capiaumont, and other good varieties. Sir Henry Stanhope was second with some fine fruit, induding Beutre Hardy, Peurre de Menige, Capital, Sir Cox, Bardener to Earl Beauchamp, was third in this class. Mr. Taylor, gardener to Barl Beauchamp, was thi second, and with the other competitors admirably sustained the

General Todtleben, and Bellissime d'Hiver; Mr. Tayler, Sherding-ten, Cheltenham, being second with Vicar of Winkfield, Catillac, Uvedale's St. Germain, and other varieties. The third prize was awarded to Mr. Froggatt, gardener to Major Wegg-Proses, who showed Beurré Diel, Uvedale's St. Germain, and Catillac.

showed Beurré Diel, Uvedale's St. Germain, and Catiliac.

In the division "open to all, and from anywhere," prices were given for stipulated varieties of dessert Apples for flavous, and said kitchen Apples for size, weight, and quadity. Mr. Hayenck was the premier prizewinter in these classes, taking eight first out of nineteen, and three seconds. The only other prizetaker securing more than one first prize in these classes were Sir Henry Stanhope and Mr. F. Bodenham, who took two each, Sir Henry's being a Pariet Mandel de Con Potent Stanhope and Mr. F. Bodenham, who took two each, Sir Henry's being for Beurré Hardy and Maréchal de Cour Pears, very fine; the other winners of first prizes were Mr. Lewis Killick, Mr. W. Stallard, Aylestone Hill, Mr. John Watkins, Mr. Cox, Madresfield Court, Rev. H. M. Ridley, Bishopstone, Mr. C. Roce, Weiford Pert, Newbury, and Mr. Taylor, Sherdington. In the class for oullness Apples Mr. Haycock's first-prize six specimens of Belle Dubois or Gloria Mandi weighted 5 lbs. 104 css.; Mr. H. Riggins was second with Warner's King, weight 4 lbs. 11 css.; and Mr. Taylor, Sherdington, third with the same variety, weight 4 lbs. 2cst. The first prize for dessert Pears for present flavour was won by. Mr. C. Ross with the Seckle; the second by Mr. Raycock with The first prize for dessert Pears for present flavour was wen by.

Mr. C. Ross with the Seckle; the second by Mr. Haycock wish
Pitmaston Duchess; and the third by Dr. Chapman with Louise
Bonne of Jersey (orchard grown). In the class for new Apples
Mr. C. Ross was among the competitors with a good serviceable
Apple of middle size, and shout which the raiser says—"It was
raised from a pip taken from a very fine specimen of Searlet Nospereil, and sown in the spring of 1869. It was planted out in
1870, and transplanted in 1874. It bere a fruit in 1878, which
was cooked in January, 1879. This year it has borne forty fruit,
seems of which were cooked in September. On both occasions it
was highly appreciated at my employer's table. It is a strong
grower and likely to be a good bearer, it being now full of fruit
buds for next year." Some were sent for trial by cooking, as well
as those for exhibition. Mr. R. H. Ballard, Homend, Ledbury,
also sent a new variety of Pippin of the same kind that he sent to
the Show last year—wix., Baylis's Kernel, which he considers a
valuable addition to dessert Apples, as the tree is free from
canker, and the fruit is in use from Christmas till March.

The French Pears and Apples were not exhibited for compe-

canker, and the fruit is in use from Christmas till March.

The French Peaus and Apples were not exhibited for compatition. They were placed by themselves on the table at the end of the Museum room. They were sent by Monsieur O. Benoit of Havre for the most part; but others had also been procured from M. Paillet, nurseryman of Seeaux, near Paris. Belle Angevine Pears (Uvedale's St. Germain), weighed over a pound each, and there were some grand specimens of Bergamotte Esperen, Duchesse d'Angoulème, Beurré Bachelter, &c. M. Benoit sent 105 varieties of Pears, and thirty different sorts of Apples, which contributed materially to the interest of the Exhibition. House. outributed materially to the interest of the Exhibition. Messa.

J. C. Wheeler & Sons of Gloucester sent a large and meritorious cullections of dessert and culinary Applies and Pears, which received the high codamendation of the Judges, and some old works on pomology imparted interest to the Exhibition.

In contributing a few notes on this Shew, the finest of its kind seen in England this year, I must congratulate the Pomona Cemmittee of the Woolhope Club on the successful result of their efforts, and there is no doubt while the Committee contains such energetic members as Dr. Bull, the Rev. C. H. Bulmer, and many others the Exhibition will increase in popularity yearly. On my first entry into the rooms containing the exhibite I was greatly struck by their appearance as a whole, giving promise, which was afterwards borne out, of a very interesting study of the different varieties. The Apple of the Show was certainly Warner's King, are titiving fact to reveal as I have consistently advected in a gratifying fact to myself, as I have consistently advocated in being planted for the last two or three years. As it is now the planting season I recommend any of your readers who have a spare corner in their gardens to plant a tree or two of this variety. If later sorts are also required, Tower of Glamis and Yorkshire corner in their gardens to plant a tree or two of this variety. It later sorts are also required, Tower of Glamis and Yorkshire Greening I have found to crop well. Although Warner's King was surpassed in weight by Mr. Phycock's splendid dish of Belle Dabois (Gloria Mundi) it is a better all-round Appla Warner's King will grow everywhere, a remark which will see apply to Belle Dabois. The neat three plates in the competitions were all Warner's King, and many other dishes of this Apple were also shown in this class, proving that it is largely cultivated in Herefordshire. Mr. Hayoock's dish of six fruits of Belle Dabois weighed 5 lbs. 10½ czs., which is good considering that Apples are one-fifth less in size this year than usual. The whole of Mr. Hayoock's collection was remarkably fine both for size, colour, and shape. At the same time for the last two qualities the Apples are of Mr. Higgins and the Pears of Sir Henry Scudamore-Stanhope were equally good.

It seemed to be a prevalent opinion at the Meeting that the climate of Kent is more switchele for the development of fruit than that of Herefordshire. Of one thing I am certain, our soil is not nearly so good as that around Hereford. The deep rich red lean that seems the staple soil of the district is precisely swited for fruit trees, especially Pears. This land, with the subsoil of red sand-

stone which can be seen protruding in huge boulders in the park at Holme Lacy, would produce Apples equal in size and superior in colour to any that I know of in Kent.

It was greatly astonished to find so few good fruit-plantations in Herefordshire, and these are confined to a few enthusiastic amateurs. The cider orchards are chiefly, too, in the flat ground. I noticed many sloping hills suitable in every way for planting, and I should certainly recommend these in preference to the low grounds at present in use. At the same time I think many of the hedges might be removed with advantage.

The deep rich colour of most of the cider Apples exhibited at the Show move that such Apples ex Blenheim Pippin and King of the

Show prove that such Apples as Blenheim Pippin and King of the Show prove that such Apples as Blenheim Pippin and King of the Pippins might be grown more extensively than they are. There is no market channel at present for the district, but if the fruit were grown there is no doubt one would soon open. I hope my Hereford friends will not think me too free in my remarks, but being greatly struck by the suitability of the soil for fruit-growing I considered the suitability of the soil for fruit-growing I consider

Lord Suffield Apple was exhibited well at the Show, but at the same time rather spotted. In many parts of Kent the trees of this variety have gradually deteriorated, and many growers have discontinued planting it. The Ecklinville Seedling again was good and ought to be in every garden; at the same time, if grown for and ought to be in every garden; at the same time, if grown for market it must be gathered before it is ripe, as it is very tender and easily bruised. Dumelow's Seedling (Wellington) were also good, and the same remark applies to Cox's Pomona, an Apple that has finished well everywhere this year. The new Hawthornden and Alfriston were also seen to advantage in many collections. Of the descert Apples some good coloured Blenheim Orange, Ribston Pippins, and King of the Pippins (Golden Winter Pearmain) were to be seen.

Of the Pears very good specimens of most of the better varieties

Of the Pears very good specimens of most of the better varieties were staged in the collections of Mr. Haycock and Sir Henry Stanhope, the Doyenné Boussoch in the latter collection being especially fine in colour. I cannot conclude these few notes without bearing tribute to the kindness and hospitality shown to a comparative stranger by many gentlemen of the city and the dis-

trict surrounding it.

The healthy appearance of the stock at the King's Acre Nurseries proves the suitability of the soil for trees, and I must congratulate Mr. Cranston on the cleanliness of the ground, which is quite the exception this year.—LEWIS KILLIOK, Langley, Maidetone.

NOTES AND GLEANINGS.

RELATIVE to the APPROACHING WINTER, a correspondent informs us that a snowstorm visited Newcastle-on-Tyne on Saturday night and Sunday morning last, the ground being covered an inch and a half deep. The storm extended all over the north of England, including various parts of Durham, Yorkshire, Lincolnshire, and Staffordshire. Snow has also fallen heavily all over Scotland. A lower temperature has prevailed for some days in the metropolitan district, and rather sharp frosts have been experienced, but no snow has fallen and very little rain, and the weather has been generally favourable for the prosecution of autumn work in gardens and nurseries.

- REFERENCE has been previously made to the GRAPES at CHISWICK, and to the excellent crop in the large vinery there. The crop is now being cut, and the fruit is commanding the highest prices in the market owing to the size and high quality of the berries. Several of them which we measured were 31 inches in circumference. When it is stated that the crop is by no means a light one, and the Vines have been planted more than twenty years, it will be conceded that they are in good condition, and that there has been no lack of skill in their management during their career. The young Vines in the long corridor—Black Alicante and Gros Colman, with one or two canes of Alnwick Seedling, have made most satisfactory growth, which is maturing admirably. This house may be expected to present a grand appearance in a few years, and will be very profitable provided more piping is afforded, for these Grapes cannot develope the high quality of which they are capable under ordinary Hamburgh treatment.
- WITH their customary liberality the Benchers of the Inner Temple have thrown open to the public the annual exhibition of Chrysanthemums in the Temple Gardens. It is somewhat early to judge the merits of the flowers, as not half of them have expanded, but their appearance is highly creditable to Mr. Newton's cultural ability, considering the unfavourable season and local disadvantages with which he has had to contend. About five hundred plants are arranged in the peculiar structure with which visitors to the gardens have now grown familiar, and for general vigour and health they leave nothing to be desired. Many of the flowers, too,

are extremely good, and this is especially noticeable in the Japanese varieties, of which James Salter, The Cossack, Fair Maid of Guernsey, Gloire de Toulouse, Mons. Charles Hubert, and Fulgore were excellent. That handsome white variety Mrs. G. Rundle is in good condition, also Beethoven, Golden Beverley, and Gloria Mundi, with the old but useful Aures Multiflora. They will continue in view during the present month, and may be expected to be in their prime in the course of a week.

- AMONG the numerous beautiful and rare plants in Mr. Joad's collection at Wimbledon Park one of most attractive at the present time is the fine Orohid VANDA CCEBULEA. a specimen of which has produced a spike bearing fourteen extremely large pale blue flowers. This handsome species is a native of northern India, and has a very distinct appearance, owing to the vigorous erect spikes, and large, delicate, pale blue flowers, that continue in good condition for a considerable time. The plant also succeeds with cooler treatment than the other species and varieties in cultivation.
- ANOTHER very remarkable feature at the above garden is the display of CHRYSANTHEMUMS in the conservatory. The collection comprises some of the best varieties, and the flowers are extremely fine for the season. The plants are tastefully and effectively arranged in a sloping bank, at the back of which is a row of Salvia splendans, the bright scarlet bracts of the latter producing a charming contrast with the lighter colour of the Chrysanthemums. Mr. Smith, the gardener, deserves great credit for the skill and taste he has evinced in obtaining such a fine display thus early.
- WE have received two of the recent works of the popular and talented authoress, Mrs. Lankester-viz., "TALKS ABOUT PLANTS" and "WILD FLOWERS WORTH NOTICE the latter being a revised edition of the work originally issued under that title. Each book is written in the pleasing and instructive style which distinguishes all this lady's productions. The volumes are well bound, well illustrated, and well printed, and are admirably adapted for presentation to children. It is, however, regretable that sundry orthographical errors should have been passed, and in the "Wild Flowers" these are especially noticeable. We find Sarraceina for Sarracenia, Galium assarine for G. Aparine, Glauceum for Glaucium, maritmum for maritimum, Chrysoplenium for Chrysosplenium, and E. Nilobium Hirsutum (page 55) for Epilobium hirsutum; also tannie is printed instead of tannin. With these exceptions the books are excellent.
- Mr. F. H. Froud, late gardener to J. Balguy, Req., Hawley Place, Dartford, has been appointed gardener to G. C. L. Lockhart, Esq., The Elms, St. Albans.
- CLEMATIS FLAMMULA is an old and general favourite. At the beginning of October we saw a couple of plants of it in full bloom trained over the porch of a quaint old country church in an exceptionally quiet corner among the South Down hills, and on the last day of that month we saw a cloud of its blossom springing out of a mass of Ivy Rægnerians on a wall close by the windows of a dwelling house. The clustering masses of its simple flowers struck us as very appropriate for the church porch, and its delicious perfuse randers it equally suitable for both places. Sweet-scented climbers should slways be planted near the windows of a house. The Honeysuckles for spring and summer, with Wistaria and Jesminum, then Clematis Flammula for autumn, and Chimenanthes fragrans for winter.
- WE have received from Mr. H. Cannell of Swanley a box of PRIMULA FLOWERS, which are extremely varied in colour, including shades of pink, crimson, lake, and white. Several of the flowers are well-formed and large.
- THE long-proposed planting of TRAFALGAR SQUARE with trees is at last about to be carried into execution. That smoke-enduring tree, the Plane, is the one selected for the purpose, and a number of young trees will be planted—certainly a preferable course to that proposed a short time since—viz., the removal of some of those established on the Thames Embankment, as large transplanted trees would not thrive freely in the heart of London. We heartily welcome this advance in beautifying the open spaces of the great metropolis.
- WE have received from Mr. Ellam of Bodorgan specimens of his new EARLY CABBAGE. The heads are heartshaped, compact, surrounded by comparatively few outside

leaves, and when cooked are of the highest quality. The examples sent are remarkable for their dwarf slender stems, and appear to possess all the properties of a superior early Cabbage. This variety is placed first on the list of the Non-pareil section in the report of the Chiswick trials, and the stock has, we believe, been placed in the hands of Messrs. Veitch & Sons for distribution.

- ONE of the best Pears now ripe in the collection at Chiswick is Belle Julie, a variety that is not so generally known nor widely cultivated as its merits deserve. The fruit is above medium size, very regular in outline, dull brown in colour, with a rather thick and russety skin. The flesh is melting, very juicy, and of refreshing flavour. The tree is a good grower, forming a handsome pyramid, and is a constant and free bearer. Mr. Barron has a high opinion of this Pear; indeed, on account of its uniform productiveness and good quality he esteems it one of the most serviceable Pears in cultivation.
- In the same garden CRATÆGUS PYRACANTHA CRENATA merits notice. It is fruiting in great profusion, the scarlet berries producing a fine effect. These are of a deeper scarlet than those of the normal species—more of a red currant colour—and are very rich. But the beauty of the plant would not be of long duration were it not netted, for the birds appear to be great admirers of the fruit, and are by no means satisfied with looking at it. C. Pyracantha is not infrequently spoiled by pruning the young growths too closely during the summer. The medium-sized short-jointed shoots should be left to mature; they then flower and fruit throughout their entire length, and in that state few evergreen wall plants are more ornamental.
- THAT remarkably handsome stove climber ALLAMANDA HENDERSONII is now bearing a profusion of its bright orange yellow flowers in the aquatic stove at Sir H. Peek's residence, Wimbledon House. The plant is a very large one, and is trained to the roof of the house, but a large number of the vigorous shoots are allowed to hang down in a natural manner. Mr. Ollerhead, the excellent gardener, states that it continues flowering during the greater portion of the year, and yields a supply of flowers of inestimable value.
- WE have received from Messrs. Carter & Co. specimens of CRESTED ORNAMENTAL KALE as grown for them by Mr. Frisby of Blankney Gardens, Sleaford. Not only are the leaves attractively coloured with pink, cream, and green, and pleasingly fringed, but from the midribs crested growths issue, imparting to the foliage a singularly curled appearance. The leaves are suitable for garnishing purposes during the winter, and the heads are fairly good and retain much of their colour when cooked, but are not quite equal in flavour to the green Kales.
- In the fine collection of Orchids at A. Sillem, Esq.'s, residence, Southall, Sydenham, are several of considerable merit. Mr. Salter the gardener is a thoroughly practical man, and evidently has a good knowledge of the requirements of Orchids, for they all appear in excellent condition. Lelia præstans and Cattleya marginata were bearing numerous handsome flowers, and the plants being suspended along one side of the house presented a very fine display. Lælia Perrinii is a handsome Brazilian species; the sepals and petals are light purple, and the labellum is tipped with rich purplish crimson. Several fine forms of Oncidium varicosum were bearing great numbers of their bright yellow flowers. The graceful Oncidium ornithorhynchum was also bright with its rose-coloured sweetly perfumed flowers. But perhaps the most striking plant in flower on the occasion of our visit was that peculiar but pretty Orchid Restrepia antennifera with its long antennæ-like petals and lower crimson sepals which are so strangely dotted with dark purple. This species is an excellent one to cultivate, as it continues in bloom such a length of time.
- In the same establishment is an extremely fine CISSUS DISCOLOE, which covers the back wall and sides of a lean-to house. It grows remarkably freely, and the foliage is large and has the fine tints which distinguish this species excellently developed. The plant is cut hard back every year, and the growth it makes in a few months is surprising. Mr. Salter finds the leaves of great service for various decorative purposes
- THE following BOTANICAL APPOINTMENTS have been recently made by the Colonial Office on the recommendation of the Director of the Royal Gardens, Kew:—H. Trimen, M.B., Lond., F.L.S., Senior Assistant in the Department of Botany

British Museum, to be Director of the Royal Botanic Gardens, Ceylon, in the place of Dr. Thwaites, C.M.G., F.R.S., who retires on a pension with the title of Honorary Government Botanist. Dr. Morris, B.A., Trin. Coll., Dubl., F.G.S., late Assistant Director of the Royal Botanic Garden, Ceylon, to be Director of the Botanical Department, Jamaica. H. Marshall Ward, Scholar of Christ's College, Cambridge, to be employed for two years as Cryptogamist in the investigation of the Coffee-leaf disease in Ceylon. He will be subordinated to the Director of the Botanic Gardens, and will have the use of the Assistant Director's house. Mr. Morris and Mr. Ward were formerly students of the Science and Art Department.—(Nature.)

BOUVARDIAS AT CHISWICK.

These exceedingly useful and beautiful plants are now very largely cultivated both by market growers and in gentlemen's gardens, as their value for decorative and cutting purposes is generally appreciated. Great quantities of the plants and flowers, particularly the latter, are sent into the chief London markets, where there is always a brisk demand for them owing to the flowers being so well adapted for button holes and bouquets. The cultivation of Bouvardias is attended by no difficulties of any consequence, and with judicious management they prove of great value during autumn and winter. The system adopted in many places of planting them out in a good-sheltered border during summer is an excellent one, for the plants acquire more vigour and continue in flower longer than those retained in pots. When taken up in September and potted they must be placed in a house, shaded and kept close until established, and if they are retained in a temperature of 60° to 65° the flowers are much more freely produced than in a cool house. Cuttings of the young shoots taken off in spring strike readily in botton heat, and the plants thus obtained after they are well rooted may be grown on in a cool situation during summer or planted out as already mentioned. Bouvardias require a rich light provus soil and abundance of water when growing in pots.

A good selection of varieties and species are now flowering

A good selection of varieties and species are now flowering at Chiswick, and from them we select the following as the most worthy of general cultivation:—Hogarth, one of the best, has downy ovate leaves and large heads of flowers, the limb of which is bright scarlet; and the tube tinged with crimson. Vreelandii, leaves lance-shaped; flowers of medium size in dense heads, white tinged with pink. Maiden's Blush, similar in habit to the last; limb of corolla light pink, tube a darker shade. Jasminoides, very pretty, of free growth and good habit; leaves smooth, lance-shaped, flowers pure white. Humboldtii corymbifiora, leaves smooth lance-shaped; corollas 3 to 4 inches long, lobes of the limb large and pure white. Longiflora flammes, fine heads of glowing scarlet flowers; effective. Leiantha, leaves ovate, downy; flowers small, bright scarlet, in dense heads. Elegans, leaves large, slightly downy; flowers of a glowing crimson hue, in large heads. Lastly, angustifolia splendens, a pretty dwarf variety with narrow rough leaves and small heads of bright scarlet flowers.—L. C.

CROXTETH.

THIS fine establishment is situated five and a half miles from Liverpool, and is the seat of the Right Hon. the Earl of Sefton. It is approached from West Derby by a long and well-kept drive about a mile and a half in length, the entrance being in a direct line with the main road from Liverpool. At about half way from its commencement the road branches to the right; the back drive, and short distance further on the drive leading to the front of the mansion, passes under one of the main roads. The mansion is a noble and imposing structure, and large additions and improvements have recently been made to it by its noble owner. Croxteth is a fine, extensive, and well-kept establishment, and was honoured with a visit from H.R.H. the Prince of Wales in March, 1878. The flower garden is situated to the left of the mansion, and the beds are cut out in the turf. No attempt is made to carry out the formal system of carpet bedding. The usual assortment of flowering plants are employed, and present in the height of the season a mass of colour, especially when viewed from a distance. The pleasure grounds beyond the flower garden are elaborate and on a large scale, containing some fine forest trees, Rhododendrons, and other choice shrubs. In front of the mansion are some narrow scroll beds, which at the time of our visit were attractively filled with Lobelias. The American

garden overlooks an extensive lawn, very even and level. From this point can be seen the large and well-wooded park, and beyond that the noble seat of the Earl of Derby. The garden presents a magnificent appearance during the time the Asalesa and Bhododendrons are in bloom. Thousands of these plants are employed, not only in the garden alluded to, but they abound in all the shrubbaries. The forest trees in this portion of the pleasure grounds are of an immense size; the trees stand separate, or at the most two together, and are thereby allowed to properly develope their beauty. They are planted on raised hillocks, a system which in bygone days appears to have been largely practised in these grounds. The fruit garden and houses are situated some distance

beyond the mansion, and yet in direct communication with the other grounds. Running parallel with the garden wall is a fine row of Limes all on raised mounds, and the wall is covered with a very choice collection of Ivies. Considerable improvements have been made by Mr. Barham; in fact,

this portion of the ground has been entirely remodelled. The first range of houses comprise three Peach houses, two of which were newly built, and the trees were planted last autumn. The third is an established house, and the trees were bearing some magnificent fruit; the other house is a late vinery, principally containing Alicantes, which were carrying a good crop of Grapes.

Fasing out of the range just mentioned we entered the fruit and flower garden. By the side of the walks are borders planted with annuals, herbaceous and hulbous plants—of which Liliums largely predominate—and the old common which Lilliums largely predominate—and the out contains white Lillium were in large numbers and appeared magnificent at the time of our visit. Many small beds in this garden were planted with Ten-week Stocks, Asters, Pyrethrums, Iberis, Pinks, and many varieties of Carnations. The Rose house is a span-roofed structure with a bed in the centre, the Roses being trained to an arched trellis. The varieties are Teas. The side stages are devoted to plants. An adjoining house of

Fig. 30.--Споктити.

the same size is devoted to Azaless and other hardwooded; pots in the Plum as well as the Cherry house. Pyramid trees plants; trained under the roof was the lovely and useful are planted at the front of both houses, and trained trees on Clematis indivisa lobats. Fuchsias are trained up each rafter the back wall. plants; trained under the roof was the lovely and useful Clematis indivisa lobata. Fuchsias are trained up each rafter and spurred-in like Vines. Another range contains two plant houses, span-roofed, high at the sides and with circular ends; and four vineries, which overlook the fruit garden. One bouse and four vineries, which overlook the truit garden. One nouse is filled with healthy Camellias and choice greenhouse Rhododendrons; the other is devoted to flowering plants. The first vinery in this range is planted with Black Hamburghs, which were bearing crops of ripe and good Grapes. The second house is partially planted with young Vines, which were doing well; they had made good wood. The next house had also nexticilly planted and the Vines were doing equally well. been partially planted, and the Vines were doing equally well. There is a range close behind the one last mentioned. The first house is planted with Cherry trees, which under Mr. Bar-ham's superior management never fail to produce an abundant supply of fine fruit. A portion of the range is devoted to Muscat Vines—old Vines which had been cut down two or three times, and were carrying a heavy crop of fruit. The last department was devoted to Flums, and we may here remark that the spur system is principally practised, and the trees were carrying a very fine crop of fruit. We very seldom see Plums grown under glass more successfully than at Croxteth. Numbers of Peach and Nectarine trees are grown in

Pines are grown in two houses, and the plants were stocky and producing good fruit, but the succession house is badly adapted for the purpose. There is one house devoted to stove plants, which also contains a very select collection of Orchids. The stove plants were of a suitable size for table decoration, &c., and for that purpose they were as fine as any we have seen. The house also contains a very fine Stephanotis, which produces its fragrant flowers in abundance. There are also houses devoted to Cucumber and Melon culture.

The kitchen garden is situated some distance from the mansion, and is a large walled enclosure. Many standard fruit trees are grown in one portion of it, and the ground was well cropped and clean. The bothy for the young men is a model. It has been wonderfully improved, although it was good before. The young men have great reason to appreciate these comfortable apartments. Our notes of Croxteth would be incomplete without reference to one of the leading features vis., the remarkable cleanliness which is everywhere apparent, and the grand lawns and fine trees. Portions of the park are being renovated, and with Mesars. Suttons' grass seeds and Mr. Barham's good management a marvellous improvement in the turf has been effected. We congratulate Mr. Barham upon the able manner in which he superintends the gardens, and thank him for the courtesy on the occasion of our visit.

BOTANICAL ORTHOGRAPHY.

On page 345 Dr. Wallace expresses a desire that opinions should be stated concerning the generalness and desirability of spelling the names of species and varieties with initial capital letters. Respecting the first part of the subject—viz., the general adoption of the method advocated by Dr. Wallace, there can be no doubt whatever that it is entirely opposed to the established and customary mode of spelling plant names which prevails in the most important botanical and horticultural works. In the "Laws of Botanical Nomenclature" adopted by the International Botanical Congress held at Paris in 1867, when 150 European and American botanists were assembled, we find that the 34th article states that "A specific name may be an old generic name or a substantive proper name. It then takes a capital, and does not agree with the generic name." This is the rule that is generally adopted, and it is only in such cases that we find initial capitals employed for specific names in the following among many other authoritative works:—Linnæus's "Species Plantarum," Steudel's "Nomenclator Botanicus," Lindley's "Vegetable Kingdom," Loudon's "Encyclopædia of Plants," the "Journal of the Linnæan Society," the "Botanical Magazine," the "Botanical Register," and Hooker's "British Flora."

In regard to the desirability of the reform suggested by Dr. Wallace I again cannot agree with him. He remarks that "Either all the specific names and those of varieties should be spelt with a small initial letter or with capitals. The present mode, in my opinion, fosters confusion between generic and specific names where spelt with capitals." Presuming such confusion to exist, I fail to see how matters would be improved by employing capital letters in every case. If the compara-tively few instances in which capitals occur in specific names are confusing, it appears to me that by increasing their number we should only increase the confusion. If reform is needed it should rather take the course of abolishing all capital initial letters in spelling the names of species and varieties, and that certainly would prove advantageous in a degree, for generic and specific names could not by any means be then con-

founded .- A BOTANIST.

HORTICULTURAL NOTES .- No. 3. NEWBURY AND DISTRICT-ENGLEFIELD PARK.

ENGLEFFELD PARK, the seat of R. Benyon, Esq., is nearer Reading than Newbury, and is about one mile from Sheale station between those towns. The house, beautifully situated on an eminence, is well backed up on the north side with trees, and near the front there is a very fine terrace garden well planted with the ordinary bedding plants. The conservatory overlooking the terrace is a very elaborate well-built structure. It contains what are probably some of the finest Orange trees in the country, a very large plant of Brugmansia arborea, and a great variety of the ordinary conservatory plants. The ranges of forcing houses, &c., near the pleasure grounds are very extensive and well stocked. Pine Apples are extensively grown, and the soil used is turfy loam only. Many of the fruiting Pines were planted out and were swelling fine fruit, especially the Black Jamaica, Prince Alfred, with Smooth and Prickly Cayennes. The quality of the latter variety is much liked, but the fruit does not kaep well. Grapes generally were looking well, crops heavy and bunches good. The Lady Downe's is considered the best late variety. The lights of the Peach houses, which are large and well furnished, can be taken off, and the trees being trained up the roof are by this arrangement kept clean, and well watered too this season by the rains. Royal George and Early Grosse Mignonne are the favourite Peaches for forcing, and these are followed by the Noblesse, Bellegarde, Walburton Admirable, and Salwey—a good selection. Violette Hative, Hunt's Tawny, and Elruge Nectarines are grown. Apricots are largely and aucoessfully grown under glass in conjunction with the late Peaches and Nectarines. Why are they not more generally grown? Moor Park is found to be the best for this work; the Boyal Apricot is also grown, but sets badly. The house for Figs is unusually large; Brown Turkey is principally grown, the Brunswick does not do well.

There is a great variety of useful and choice stove and greenhouse plants grown here. In the stove a plant of Allamanda

Schottii planted out and trained up the roof was flowering grandly, and would continue to do so for a long time. Jaminum sambac is treated in a similar manner, and proves very nesful. Of Orchids the best specimens were Peristeria elab, Dendrobium densifiorum, D. Palmerii, Coelogyne cristata, &c. A good and well-grown selection of Crotons consisted of amabilis, Weismanni, majesticus, undulatus, and Veitchii. Camellias for cutting purposes are planted in a large pit, and must prove very useful. Bouvardias are largely grown, as also are Poinsettias, Euphorbias, Deutzias, &c. There are many fine specimens in the fernery, very noteworthy being the plants of Latania borbonica, Areca Baueri, Alsophila excelsa, Adiantum concinnum latum, Asplenium paniculatum, &c. Immediately opposite the principal entrance to this house there is a fine bank of Adiantum cuneatum, out of which springs a good specimen of Cycas revoluta, which is a very effective arrangement.

The fruit walls are particularly good and well furnished, Englefield being famous for its Pears. The late Dr. Lindley was a great admirer of these fine Pear trees, which are said to was a great admirer of these line real teles, which are said to be one hundred years of age. They are still vigorous and prolific, as are also the younger trees throughout the garden. The most fruitful were the Jargonelle, Marie Louise, Brown Beurré, Joséphine de Malines, Duchesse d'Angoulème, Passe Colmar, Zephirin Gregoire, Brockworth Park, and Seckle. Peaches again on the walls were for the year remarkably healthy and fruitful, which in a great measure is owing to the use of Parham's wall protectors. These consist of a light iron framework or coping permanently fixed to the wall, and in which are slid squares of glass. These are only temporarily fastened, and are taken out and stored away when no longer required. Light blinds which can be pulled up or down as required are suspended from the coping. They not only protect from frost but easterly winds, which are particularly injurious to the young growth of Peach trees, but can be warded off by a judicious use of the blinds. The crops in the kitchen garden looked well, and the whole place reflected much credit on Mr. Coombe, the gardener in charge.—W. LGGULDEN.
In my remarks on Welford Park I inadvertently stated that

the Grove End Scarlet Strawberry was the favourite for forcing purposes. It should have been for preserving purposes. Mr. burposes. It saturates the had for many years grown this variety for preserving, no other Strawberry jam equalling that made from the Grove End Scarlet.—W. I.

GRAPES RIPENED WITHOUT FIRE HEAT.

On the 10th of October some specimens of Grapes grown and ripened in a cool vinery without the aid of fire heat in any shape whatever were submitted to the Editors of this Journal who were kind enough to send in writing to the author of this article the following opinion upon some of the specimens-"The examples are very interesting as specimens of what may be achieved with a cool vinery without the aid of fire heat. The colour of the black varieties was perfect, and the flavour of Black Hamburgh and Foster's Seedling were all but perfect. while Dr. Hogg was ripened with a flavour which is quite marvellous for a variety belonging to the Frontignan class.

How these Grapes have been grown in a summer cold, wet, and dull to a degree almost without precedent, so as to merit a commendation like that given above, may be a matter of interest to many amateurs besides the writer of this notice. There are, for instance, many professional men, fond of their gardens as a source of pleasure and as a means of wholesome relaxation from graver pursuits, who would gladly grow Grapes were it not for the belief that without the help of flues or hot water and the services of a regular gardener they could not expect to succeed in their attempt. A proof that this success is within the reach of one amateur may serve to encourage

others to try and follow in the same path.

As a first step to this end a knowledge of some simple rules of Grape-growing must be acquired, for the saying of Lord Bacon that "a cripple in the right way will beat a racer in the wrong" is as applicable to this as to other though one of the say of t knowledge may be speedily acquired by the perusal of one or more of the little manuals on the subject and of the articles, written by masters of the art, which often appear in the Journal of Horticulture. Observation will soon give force and meaning to these teachings. Any little difficulties that may occur in the progress to knowledge may be made the subject of an appeal to the Editors of the Journal, and information and advice will at once he given with the progress. For advice will at once be given with ever-ready courtesy. For

the rest, to be in earnest and to take a loving and constant interest in the matter are conditions of success not peculiar to

Our vinery faces due south, and is 30 feet long by 12 broad made measurement. The whole of this space is enclosed by a brick wall, which rises above the level of the outside soil, on the north to a height of 8\frac{1}{2} feet, and at the front and sides of four or five courses of brick only. Between the top of the bricks in front and the plate on which the rafters rest is a continuous line of ventilators, ten in number. Each one is a simple well-fitting board 3 feet long and 11 inches wide, having two hinges below and opening outwards and downwards. When closed it is fastened by a single metal button. These short ventilators can be speedily opened and shut from the outside; and it is possible by their means to ventilate individual Vines that happen to be most forward without lowering the temperature around those that may not yet require front ventilation. The roof is a combination of span and lean-to: the front rafters, of which, including the two outside ones, there are eighteen, being 12½ feet in length, and those at the back 5½ feet. The ridge plate between them is 11½ feet above the path. The angle formed by the front slope of the roof and the line of this latter measurement will be seen, therefore, to be very acute. At sither extremity is a door 2 feet 6 inches wide, and between them runs a path, leaving a border of 3 feet on the north and a broader one to the south. Each of these berders slopes somewhat to the path, so that the soil on which the front row of Vines is planted is nearly on a level with the top of the brick wall on the south. I ought to mention that this path is a series of short planks lying across two longitudinal iron sleepers (2-inch gas piping would answer well), which are supported upon occasional brick piers. The object of this is, of course, to prevent treading on the soil, but the presention is perhaps hardly necessary. The top ventilators are boards similar to the lower ones, lying just below the nidge plate on the north side, having the hinges above and in length, each one covering two spaces between three contiguous rafters. They open by cords from the inside in the usual way. To guard against the effects of exceptional sun heat there are also three ventilators in the back wall, and a narrow one from top to bottom between is and the doors.

In 1877 ten good Vines were planted at equal distances along the front border 20 inches from the south wall. They run in the following order from east to west:—Foster's Seedling, Black Hamburgh, Golden Champion, Muscat Hamburgh, Black Hamburgh, Dr. Hogg, Madresfield Court, Mrs. Pince, Muscat of Alexandria, and Lady Downe's. It will thus be seen that the Grapes requiring most heat are towards one end of the

building.

At a distance of 9 inches from the back wall is another row of Vines. The plants are 4 feet apart, and are trained to stout upright wires; they are not intended to climb more than 6 feet high. Two Vines of Trentham Black and one of Foster's Seedling in this row bors excellent Grapes this summer.

There is nothing unusual in the soil in which these Vines

grow most luxuriantly. Turves from old pastures 4 or 5 feet thick, the grass downwards, cover the bottom. Upon this is a mixture of turfy soil, strong rather than otherwise, old mortar rubbish, and well-decayed horse and pig manure. A good supply of bones, such as every family furnishes, coarsely broken, was added. I took care that large hollow bones were not much broken, for they help to keep the soil open, and the roots of the Vines speedily entering their cavities seem to revel on what they find within. To receive this soil the ground within the vinery was removed to the depth of $2\frac{1}{2}$ feet. At the bottom ware placed some inches of broken stone and lime concrete, and upon this ran several rows of 2-inch drain tiles, all converging towards the lowest point. So that the Vines may be said to be planted in a box with walls at the sides and concrete at the bottom, and having no other outlet than that by which the drainage water escapes. The rain water falling on the roof is conveyed into a spacious tank in a greenhouse adjoining the west end of the vinery.

Whatever success has been attained in this house in growing Grapes without the help of fire heat is owing mainly, I think, to—first, the form, &c., of the house, facing due south, with as much glass and as little wood as possible; the former fitting well, and the stope of the roof being at an angle favourable to the direct transmission of the sun's rays. Then the western end and the northern slope of the roof admit the afternoon and evening sun, the ground on which the building stands sloping gently from east to west.

Secondly, watchfulness in regard to the use of the ventilators. The giving of air from the top, whilst the Vines are growing during any odd hour in the day when the temperature within could not be lowered by so doing, and on cold days not opening the ventilators at all, or opening one here and there perhaps only to the extent of an inch or two. When the Grapes commenced colouring one or more of the front ventilators were opened, choosing those that were near the most forward Grapes. Above all, during the cold dull summer, remembering that the sun heat was a thing to be treasured, if the sun shone for an hour or two only and that feebly we never opened at all, but used the sun as a means of warming the house for hours after it was gone. I am sure, also, that our operations have been much helped by the wall at the back of the vinery. Generally speaking such walls are whitened by limewash: in this way the starfage of the brick is rendered smooth and almost incapable of absorbing much heat; whereas the wall of rough dark bricks absorbe a large amount of heat, and from its broad surface long after the sun has set is radiating far into the night a gentle warmth, playing the part in fact of hot-water pipes. During a hotter summer more air would of course be necessary; but the extent to which the ventilators are to be opened on all occasions will be taught by observation. It is a question of watching day by day, and feeling the way to what is right by the effects produced. I can only say that our Vines have been most healthy, the leaves large and dark, the wood hard, short-jointed, comparatively pithless, and speedily ripened. So far also we have had no insect pests.

Thirdly, the roots of the Vines are confined strictly within the house. It is possible that some of the failure that has been experienced this season in giving colour and quality to Grapes in heated houses may have been owing to the roots being outside, in soil cold and perpetually drenched with rain. It has always seemed to me difficult to reconcile the practice of a high temperature for the ascending portion of a Vine, and a low one for the descending portion, with what is observed in Nature. Certainly in the warm parts of Spain and France the Vines grow usually in a rocky dry soil, where the roots as well as the green parts must often be well nigh baked. There exhausted in the course of many years, as I know from some experience of Grape-growing elsewhere than where we now live. But even were it otherwise, nothing is easier than gradually to remove the old and substitute new soil.

Other advantages attending the intramural situation of the roots are the facilities for watering and mulching. As soon as the buds begin to swell the ground is gradually covered with a layer 2 inches thick of chopped fresh horse droppings, the effect of which, besides affording food to the Vines, keeps their roots near the surface and saves much labour in watering. Every morning whilst the Vines are growing and until the period of colouring is at hand, the gardener's assistant during the breakfast time of the family pours over, first one and then another section of the soil, the slope from the dwelling house. I may add, that excepting for the purposes of watering, making tidy, &c., the gardeners seldom enter the vinery, and for this simple reason: It is the delight of myself to do the pruning, training, &c., whilst a gentler hand, guided by dexterity and judgment, has for years past found pleasure in thinning the bunches. Others of our family attend to the ventilation, and it is remarkable how short a time each day suffices for everything that has to be done.

I will conclude this account by referring again to the pleasure and recreation attending the management of a small vinery. The watching from day to day the progress of the Vines from the moment of pruning, the swelling of the buds, the opening of the flowers with their sweet delicate fragrance, to the time when the purple and golden tints steal over the swelling berries, deepening more and more until the heavy bunches, whilst yielding enough to the owner, are ready for the bedside of the sick or the table of friends.— A SURREY

Of the Grapes above referred to we may add that the Black Hamburghs were quite ripe, of good size, and well coloured, very julcy and refreshing, but flesh lacking urmness.

Champion, large, quite ripe, but not of high quality.

Muscat
refrectly ripe.

Foster's of Alexandria, large, good, but not perfectly ripe. Foster's Seedling, quite ripe, good berries, and of good quality. Dr. Hogg, very good berries, quite ripe, and of excellent flavour. Muscat Hamburgh, berries not large but well coloured and of good quality, but flavour not fully developed. They were the best examples we have seen this year of Grapes ripened without fire heat.—EDS.]

SLUGS.

FOR once I cannot agree with Mr. Radclyffe when he says "brewers' grains are a farce." Here slugs have been devouring almost every plant. On Mr. Richard Smith's recommendation we tried young ducks. They were soon gorged, and then improved their digestive organs by eating a good bed of Myosotis dissitifiora, all our young Cauliflowers, Wallflowers, Lothian Stock, &c.; they sat upon our named Polyanthuses and spoilt them, so we ate the ducks. The Cornwall plan with fresh brewers' grains and lime has answered admirably. In one month we have destroyed over three bushels of slugs. My man places little heaps of fresh grains at sunset twice a week; in an hour hundreds of the slugs would be wending their way to the grains. In about three hours the gardener goes round with a light, and the boy sprinkles quicklime on the heaps.—R. H.

GRAPE VINES FROM EYES.

MR. GILBERT in his letter on growing Vines in pots holds it next to impossible to grow well-ripened fruiting canes from eyes the same year. I have, however, had no difficulty in so prowing them, and have obtained prizes for the fruit. This was, I believe, first accomplished by Mr. Pillins forty or fifty years ago, who at that time was living at Tortworth Court as gardener to the Earl of Ducie. This mode of propagation was then unknown, I believe, to the leading nurserymen, who increased their stock by layers.—JOHN MACKEY.

LATE GLOBE ARTICHORES.—We are still (November 1st) cutting some good dishes of these, and we find them most useful at this season of the year. Old plants are generally past bearing by this time, but there is no difficulty in getting the suckers which were planted in April to fruit so late as this. Another plan is to cut the heads and stems off old plants as early in the season as possible, and this generally induces more young growths to start from the bottom, which produce fruit during October and November.—A KITCHEN GARDENER.

WORK FOR THE WEEK.

FRUIT HOUSES.

Orchard House.—Although it is desirable whilst the foliage is on the trees to repot some, and to attend to lifting or root-pruning others that are planted out, yet there is danger in a season like the present of performing these operations too early, shrivelled wood and immature buds being the result. In most cases it is advisable to defer top-dressing where trees in pots have rooted into the borders until the leaves show indications of falling, as it is injurious to deprive them of roots whilst the wood is compais injurious to deprive them of roots whilst the wood is comparatively soft and the buds undeveloped. All trees in pots should be shifted into larger pots, or the soil top-dressed if necessary, whilst those rooting beyond the pots should have the roots cut off close to the pots when the leaves show indications of falling, and the soil from the surface removed to as great a depth as practicthe soil from the surface removed to as great a depth as practicable, the portion taken off being at once replaced by fresh compost—turfy loam, with a fourth of well-decayed manure and a sprinkling of half-inch bones in a rather dry state—so as to admit of being rammed down as firmly as possible. A good watering will then be necessary, it being essential that the soil be kept moist until all the leaves are off, after which but little water will be required. Young trees should be shifted into pots 15 inches or oe required. Young trees should be shifted into pots to inches or 18 inches in diameter according to their requirements, providing efficient drainage and ramming the soil as firmly as possible. Trees planted out should be examined, and if growing too luxuriantly or not fruiting satisfactorily they must be carefully lifted. chortening back the strongest roots, and laying them in fresh compost, afterwards mulching with short manure. The effect of lifting is to keep the trees in a fruitful condition, counteracting the tendency to produce gross unripened wood. When the leaves of trees in pots have fallen, the trees may be placed outdoors in a sheltered situation and on a bed of sahes, the surface of the soil being protected by cocoa-nut fibre refuse. By placing the trees outdoors for a time the house will be available for Chrysanthemums. Ac. If there he any insects avoid the compounds of anthemums, &c. If there be any insects avoid the compounds of clay and others that leave a thick deposit upon the shoots and buds, and syringe with quassia water, I b. of chips to four gallons of water, boiled for fifteen minutes, adding when cooling I b. of soft soap. *Peaches* suitable for orchard-house culture are Early Beatrice, Hale's Early, Early Grosse Mignonne, Early York, Grosse Mignonne, Royal George, Bellegarde, Barrington, Princess

of Wales, and Walburton Admirable. Nectorines: Lord Napier, Stanwick Elruge, Elruge, Pine Apple, Pitmaston Orange, Violette Hâtive, Victoria, and Albert Victor. Plums: July Green Gage, Angelina Burdett, Jefferson, Kirke's, Woolston Black Gage, Transparent Gage, and Coe's Golden Drop. Pears: Souvenir du Congrès, Beurré d'Amanlis, Williams' Bon Chrétien, Louise Bonne of Jersey, Beurré Hardy, Maréchal de Cour, Durondeau, and Doyenné du Comice. In cold localities where Apples do not attain perfection for dessert purposee, Early Harvest, Early Strawberry, Kerry Pippin, Beauty of Waltham, American Mother, Cox's Orange Pippin, Golden Pippin, Ribston Pippin, Margil, De Neige, Api (Lady Apple), Mannington's Pearmain, Mela Carlo, Melon Apple, Adam's Pearmain, and Scarlet Nonpareil.

Vines.—Since the certainty of keeping late Grapes in good coadition up to May has been clearly established very early forcing has in many instances been given up. Where, however, it is still necessary to have fresh ripe Grapes in April there must not be any further delay in starting the Vines. If in pots a good supply of fermenting material for affording bottom heat to the roots should be in readiness. A good bed of Oak or Beech leaves with a little stable dung added will greatly facilitate the starting into growth, and will be more beneficial to the Vines than fire heat alone, the pots not being subjected to a higher temperature than 66° to commence with, and in the case of having the Vines planted out in inside borders a bed of the material above named will be advantageous. A temperature is required to excite the buds than is the case with those not started until December or January. Syringe three times a day, and keep every part of the house moist by sprinklings in bright mild weather. Remove all matured leaves from Vines going to rest, keeping the house cool, airy, and dry. Push on the pruning of Vines in succession houses, thoroughly cleansing the glass with clear water, and the woodwork with soap and water. The roes should only have the

mended and tied to the trellises, a start may be made about the middle of the month. The house may be kept close, but admitting air freely above 50°, employing fire heat to prevent the tempera-ture from falling below 35°. The slower the trees are excited the stronger will be the blossoms. The outside border must be well protected with litter or dry fern, and if wooden shutters or tarpaulin are at command they will be advantageous in throwing off excessive wet. The inside border must be brought into a thoroughly moist condition. The trees in the succession houses thoroughly moist condition. The trees in the succession houses may be pruned as they become devoid of leaves. If former instructions have been carried out but little pruning will be required, and, except in shortening back any shoots that may be necessary for the origination of new parts, the less the knife is used when the trees are leafless the better. The houses should be thoroughly repaired and painted, and the trees dressed with an insecticide before being tied to the trellises. Keep the house as cool as possible, not allowing the inside borders to become very dry.

FLOWER GARNER. FLOWER GARDEN.

Vacant beds should be manured and deeply dug or trenched, and planted with bulbs and spring-flowering plants or dwarf bright shrubs. There is no more necessity for empty window boxes than for bare mounds of earth in the flower garden in winter and spring. A change of occupants is now absolutely winter and spring. A change of occupants is now absolutely necessary. Small evergreen bushes have a cheerful and pleasing appearance, especially when a good selection is made of plants varying in character or growth, form of leaf, and tint of foliage. Brica herbacea carnea, Skimmia japonica, and Euonymus radicans variegatus are good for margins. Aucube japonica mascula, A. limbata, A. longifolia, Laurustinus, Osmanthus ilicifolius aureus, and O. variegatus nanus, with green, golden, and silver tree Ivies have bold foliage; Cupressus erecta viridis, C. nana glauca, Cryptomeria elegans, Thuja aurea, and Thujopsis borealis have small foliage. Dwarf shrubs 12 to 18 inches high can be arranged in single line in ordinary window boxes, with a line of smaller plants in front, and between the taller plants may be introduced dwarf single line in ordinary window boxes, with a line of smaller plants in front, and between the taller plants may be introduced dwarf plants of Chrysanthemums. They will last until near Christmas, and may be succeeded by Hyacinths, Narcissi, and Tulips. Along the front of the boxes, in the spaces between the shrubs forming the margin, should be introduced a few Scillas, Crocuses, and Snowdrops, and just behind them or over the bulbs double Daisies, Primroses, Alpine Auriculas, &c. The bulbs and spring flowers may be dispensed with, and the small-leaved green and variegated Ivies planted to fill in the intervening spaces and hang down in front of the box. Sedums, Saxifragas, and Sempervivums may be introduced with good effect; indeed, it is not difficult to design elaborate arrangement, the difficulty is in using plants that will endure the winter in towns.

Greenhouse.—China and Tea Roses that were cut back and potted in spring, and have been placed out of doors in a sheltered situation and well attended to during summer, will now have abundance tion and well attended to during summer, will now have abundance of flower buds, and if placed in a light house will at once open their blooms, the temperature being from 45° to 50° by artificial means. If a considerable number of plants are treated in this way for autumn flowering a succession of flowers may be had by placing some of the plants in a house from which frost is only excluded, introducing them to gentle heat as required. The Tea-scented and China Roses from their continuous flowering are the best for using in this way, and having wall extended to in summer with water and in this way; and being well attended to in summer with water and liquid manure, and keeping them free from insects, they will be found very useful for furnishing cut flowers until the end of the year. Carnations for producing successional flowers must be well exposed to light and be well attended to with water, as anything like a check to steady progressive growth inimically affects the flowering. A temperature slightly warmer than an ordinary greenhouse is essential to have blooms freely produced in winter, and the plants must be well grown previously or the flowers will be few and poor. Mignonette to succeed in the winter season must have a light position, otherwise it is weak and the spikes are puny. The earliest flowering plants will require to have the principal shoots tied up to neat stakes. Free ventilation is essential, and a temperature of about 45° in the night to 50° in the day is desirable for plants required to bloom, but successional plants should be kept cool and airy. Cyolamens now producing their flowers should be kept near the light in a temperature of 50°; more heat will bring up the flowers quickly, but they are not by any means nearly so enduring in a cut state or for decorative purposes as those forwarded in moderate heat. Fuchsia cuttings struck in August form by far the best and most satisfactory plants for next season's bloom, and should now, if not already done, be potted into pots 6 or 7 inches in diameter, placing them in a house with a temperature of 50°. Keep the plants tied up and the leading shoots stopped as may be necessary according to the natural habit of the variety. If red spider are present syringe on the under side of the leaves with a soapy solution. Old Fuchsias that have done flowering and which can be brought into bloom to precede the others should now be carefully dried off, but if required early they must not be kept be carefully dried off, but if required early they must not be kept too dry. They may be stored in any place free from frost, but not under stages where they get the drip from other plants. Primulas should be kept near to the glass, and they succeed admirably in a temperature of 45° to 50°. Liquid manure should be occasionally given, as with good ventilation and a little heat they are not so liable to damp off as in a cool house. Zonal Pelargoniums that have been prepared during the summer for winter flowering will be producing their trusses in a temperature of 50° to 55° with moderate ventilation. The conservators will now be gray with be producing their trusses in a temperature or our moderate ventilation. The conservatory will now be gay with moderate ventilation. These moderate ventuation. The conservatory will now be gay with Chrysanthemums, which in most places are a month late. These with the most forward Primulas, Salvia Heeri, and S. splendens will do good service. Early-flowering Epacrises and Ericas, Camellias, Vallotas, Epiphyllums, and Solanums are very useful. Tacsonia Van-Volken and Lapageria roses and alba are very useful. ornamental. Other climbers of a coarse character should be freely pruned, so as to give as much light as possible to the plants underneath. Hardwooded plants should be frequently examined, and if mildew appears promptly apply flowers of sulphur, allowing it to remain on for about a week, then syringe it off, the plants being laid on their sides so that the sulphur does not by any means reach the soil. Apongeton distachyon grown in shallow tanks or deep pans filled with water, will, if afforded plenty of light, continue producing its white hawthorn-scented flowers through the winter in a temperature of 45° to 50°. The ordinary stock of greenhouse plants will only require fire heat in case of frost, 40° being a safe minimum, and occasional fires in case of continued dull damp weather, ventilating rather freely in mild weather. Funigate upon the first appearance of aphides, and for thrips two or three nights consecutively. Water in the early part of the day, but lessened supplies will now be necessary. ornamental. Other climbers of a coarse character should be freely

TO CORRESPONDENTS.

* All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at All articles intended for insertion should be written on de of the paper only. We cannot reply to questions one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return communications.

BOOKS (J. H., a Subscriber).—We do not know of any other publication of the kind, nor can we render you further aid in obtaining the manual we

ADDRESS (T. U.).—We have the manual to which you refer, but the author appears to have changed his residence, and we do not know his

TRAINING FRUIT TREES (A. R.).—The system of training to which you refer is termed the palmette verrier, and is very good. You can train as many branches as you like from each tree. If you purchase trained trees such as the one shown in your sketch, with five branches, they should be planted about 5 feet apart, the branches being trained on the wall about a foot asunder. Five branches only occupying a space of 3 feet 9 inches are too much crowded. See remarks on thin training in another column.

GALVANISHD WIRE (J. Otter).—It has no injurious effect on plants, Where injury is done to the shoots and branches of trees it is generally the result of the wind chafing the branches against the rough surface that exists on some galvanised wire, and which may be felt by passing the wire through the fingers.

AERIAL ROOTS ON VINES (D. W.).—These are promoted by a moist atmosphere, and are generally the most prevalent when the root-action in the borders is defective. This appears to be the case with your Vines. We should renew the outside border and raise the roots, leaving the inside border to support the Vines until fresh roots are produced outside. You will find reference to compost and lifting Vines on page 240 of our last issue.

SEEDLING PRINTLAS (H. E. F.).—The flowers are distinct and novel, the prevailing colour being yellow with a faint green tint margined with white, the segments being deeply fringed. The value of the variety depends in a very great measure on the free-growing character and free flowering properties of the plants. Submit plants to a nurseryman.

perties of the plants. Submit plants to a nurseryman.

REMOVATING OLD APPLE TREES (C. B.)—Remove all dead wood and much that is seriously cankered or otherwise obviously useless, but do not prune nor thin out the branches excessively. When the trees are thoroughly wet, as after a very heavy dew, dust them well with freshly slaked lime. A ladder will be necessary for the dusting to be effectual, and the lime must not be used sparingly; it will adhere to the branches and spurs, and will kill the moss. This alone will beneft the trees, and the removal of the surface soil from a good distance round the stems, and applying a heavy dressing of rich manure, will further benefit them. If the trees are very old it would be well to plant young ones, retaining the old until the young trees become fruitful. It is a mistake to allow old trees to become completely worthless before young trees are planted, yet that mode of procedure is very common in orchards and gardens. For destroying scale and American blight see reply to "N. J. M."

Exhibiting Graphes (Young Gardener). — If the stipulation in the

reply to "N. J. M."

EXHIBITING GRAFES (Young Gardener).— If the stipulation in the schedule is "the best collection of Grapes in not less than four varieties" you cannot be disqualified for only exhibiting one bunch of each variety. Sloping stands should be made for the Grapes, an inch or two high in front and thrice that height at the back, the top or slanting portion being a few inches longer than the bunches, and wide enough for one or as many bunches as you choose. The back of the stand should be an inch above the level where the Grapes are placed, and in the angle so formed the lateral bearing the bunch can be secured. The stands should be covered with smooth white paper, and the Grapes as they are cut be firmly fastened in their places. The stands should then be placed in boxes and conveyed to the exhibition; and the Grapes should arrive there without a berry crushed or a particle of bloom removed. Many prizes are lost by rough and imperfect packing and a lack of care in transit to the shows.

STARTING CYCLAMENS (Mrs. M.).—Your house having a temperature of

STABITING CYCLAMENS (Mrs. M.).—Your house having a temperature of 55° to 60° will be suitable for the Cyclamens, and it will not be necessary to place bellglasses over the corms. You must not water them every day, as there is little or no growth to appropriate the moisture, and the soil would therefore soon become soddened and sour. If the soil in the pots is very dry apply water copiously, two or three times if necessary, until the whole is moistened, then do not give any more water until the soil crumbles when rubbed with the finger. It may only be in that state once or twice a week if the weather is dull. The only safe rule for watering is to wait until the soil is rather dry, not by any means dust dry, and then to give sufficient tepid water to penetrate the entire mass. When growth has fairly commenced turn the plants out of the pots and remove as much of the old soil as you can without seriously disturbing the roots, and repot in fresh compost—light turly loam two parts, decayed leaf soil one part, adding crushed charocal and sand to keep the compost porous. Bellglasses placed over cuttings should be wiped dry once a day, and as soon as the cuttings present signs of growth the glasses must be tilted, slightly at first, then admitting more air until they can be dispensed with entirely.

LEVELLING AND RELAYING LAWN (Irisk Subscriber).—Dig the ground STARTING CYCLAMENS (Mrs. M.) .- Your house having a temperature of

LEVELLING AND RELAYING LAWN (Irisk Subscriber).—Dig the ground early in spring, turning in the turf, and in doing so throw the hills into the hollows, making the surface as even as possible. Allow it to settle until the early part of April, and again level the surface, and if the ground be poor a good dressing of well-decomposed manure may be given and pointed in. At the first prospect of rain afterwards sow a mixture of lawn grass seeds, raking the seeds lightly in and roll well down. Mow the first time with the scythe, and afterwards with the machine. A lawn, we treated in that, way last spring had a good appearance by June, and is now quite equal to another we laid with turf at the same time. had a good appearance by with turf at the same time.

IMPROVING TURP AMONG SHRUBS (Idem).—Provided the shrubs do not include any of the Coniferse or others that produce roots near the surface dig the ground between the shrubs, removing any deep-rooted weeds; and in April sow lawn grass seeds, preparing the ground as advised for the

PRAR TREES BLIGHTED (N. J. M.).—No. 1 is infested with the Pear tree oyster scale (Aspidiotus cetreeformis). Parafin applied with a hard brush will destroy it, but it must be applied when the trees are at rest, and not be allowed to run down the stem to the roots; or a solution of nicotine scap, 8 cm, to a gallon of water, will destroy it, applying the mixture thoroughly with the brush; or 1 h. soft scap to a gallon of water, adding a wineglessful

each of spirits of turpentine and methylated spirits. No. 2 is attacked by mildew. Take equal proportions of fresh unslaked lime and flowers of sulphur, mix with water, and apply it with a brush.

HEATING PIT WITH PARAPFIN STOVE (New Subscriber).—The "Reonomic" paraffin stove would answer your purpose, and cause no injury to the plants, providing, of course, they are not so near as to be affected by the heat. State the size of your pit, and write for particulars to A. E. Syers, Bowdon, Cheshire.

Bowdon, Cheshire.

CONSTRUCTING A PEACH HOUSE (J. B.).—The top ventilation must be double that you are providing, or a light 2 feet wide opening the entire length of the house. A board will not answer, and to leave an opening at the top of a lean-to in summer would spoil the fruit should rain prevail when it is ripening. Glass should be used, especially as you propose planting trees against the back wall, as they will need all the light possible, the front trees not being allowed to extend too high up the front trellis, or the back trees will be so deprived of light as not to fruit satisfactorily. No manure must be mixed with the losm, and a twentieth part each of crushed bones and charcoal is sufficient. By all means put in a 4-inch flow and return pipe, the joints of which after they have been stopped with tarred rope may be made with Portland coment, which will answer quite as well as iron filings. The best varieties of Peaches are Hale's Early, Dr. Hogg, Grosse Mignonne, Royal George, Noblesse, and Earrington. Nectarines: Lord Napier and Eiruge.

FERMS FOR PANS (J. H. C.).—Place at the bottom of the pan a layer of large potaberds, concave side downwards, and over them a layer of smaller pieces, the depth of the drainage being regulated according to the capacity of the pan. Upon the potaberds should be placed some moss or the rough fibrous part of the peat to prevent the soil from being washed-in amongst the drainage. The soil must consist principally of peat with a small proportion of loam and abundance of silver sand theroughly incorporated. Any of the following species would probably suit you:—Asplenium Adiantum nigrum, A. fontanum, A. lanceolatum, A. marinum, A. Trichomanes, Cystopteris fragilis, and Trichomanes radicans. The number of roots required would entirely depend upon their size.

POTATORS (Constant Reader).—We do not know of any varieties of Potatoes that will produce good crops in "ground almost coal ashes." Mystt's Ashleaf is a productive early variety. A good mideeason round Potato is Schoolmaster, and a strong-growing late Kidney that has resisted the disease this year in a remarkable manner is Magnum Bonum.

AQUA DULOB BRAH.—"J. R." wishes to know where he can obtain seed of this Bean.

ROSE ELECTION (R.J.Clarke).—If you send $3 \frac{1}{4}d$. in postage stamps to the publisher, informing him that you require No. 369 of the Journal, it will be sent to you. That number contains the election of exhibition varieties.

Pansies (Amaleur).—They may be planted now in good yet well-drained soil, and if a little light gritty compost is placed round their roots it will be beneficial to the plants. They should be planted rather deeply, and means must be resorted to to prevent them being injured by the wind. The soil should also be firmed round them at suitable intervals after frost, which sometimes raises them partly out of the ground. Very choice varieties we should place in pots, plunging in ashes in a cold frame, and there winter them, ventilating very freely during all favourable weather.

them, ventilating very freely during all favourable weather.

SOIL FOR ROSES (L. T., Putney).—Finely chopped clay or strong loam of any kind would be a good addition to your light soil. But if by removing the gravelly subsoil you can make the soil good to the depth of 2 feet by adding manure liberally, planting firmly, and giving heavy top-dressings of manure, we think the Roses will fourish. When the site has been thus prepared, we have seen Roses thrive very well in light soil. They should be on Manetti stocks. Liquid manure would be very valuable during the growing season, and the follage must at all times be kept free from insects.

HEATING A GREENHOUSE (Captein).—Either a small hot-water apparatus or a fine would be much better than attempting to heat such a house as yours with petroleum stoves.

STOVES FOR HEATING (C. Pearse).—Such a stove as you refer to with an evaporating dish on the top to be used when required, and a pipe to carry the elements of combustion into the open air, would, we think, answer your purpose.

BULB FARMS (J. G. G.).—You might possibly obtain the information you require by writing to Messrs. H. E. Krelage & Son, Haarlem; or to Ant. Roosen, Overveen, Haarlem, Holland.

Ant. REMOVING VINES (H. F. Pop).—Vines five years old may be safely removed provided due care is exercised in taking them up and replanting. First, have the new border in readiness for their reception. The site being well drained, form the border 2 feet deep of turfy loam, a bushel of inch bones being added to each one-horse cartload of soil, and as much wood ashes and burnt soil as you can obtain. In taking up the Vines dig a wide and deep trench along the front of the border at the same distance from the base of the Vines as the rods are in length. Work from this trench with steel forks, undermining the roots and removing the soil carefully. As the roots are liberated turn them adde and over them with mats to prevent them drying. Any roots that are punctured or injured should be cut off above the bruised part with a sharp knife. In planting place the roots straight and cover them an inch or two deep with prepared compost—half fresh loam and half wood ashes—with half a peck of bone dust to each barrowful of the compost. On this place 4 inches of the ordinary border soil, and surface it with 3 inches of good manure. In the spring let the Vines grow naturally—that is, do not "assist" them with fire heat, and they will soon be established in their new position. If you have to remove the Vines at once to the new garden before the leaves have failen you had better cut them off, as they will have now assumed their antunnal tints, and their removal will not materially injure the Vines. If allowed to remain the evaporation from their surfaces might cause the wood to shrivel. Frume term in December.

ANTIQUITY OF THE AUTUMN BERGAMOT PEAR (Lex).—The following note by Dr. Hogg, in the last edition of "The Fruit Manual," refers to the supposed antiquity of this Pear:—"It has been stated by Switzer, and by some subsequent writers, evidently on his authority, that the Autumn Bergamot 'has been an inhabitant of our island ever since the time that Julius Cessar conquered it. Possibly it was the Assyrian Pear of Virgil (Quod a Syria translata fusion), may some commentators, and was, as may be deduced from thence, part of the farniture of the once celebrated and famous gardens of Alcinous.' As this can be only conjecture on the part of Switzer,

and unsupported by any well-founded evidence, I think it extremely improbable. It is rather singular, notwithstending this statement, that he is the first English author who mentions it. It is not noticed in the lists of Rac, Worledge, or Evelyn, nor in the very comprehensive list of Leonard Meager, of the fruits which were cultivated in the London nurseries in 1688, Neither is it even mentioned by Res, Ralph Asastin, Parkinson, nor William Lawson, and, indeed, by no sushor is it recorded prior to Switzer himself, Parkinson speaks of the Wister Bergamot as 'of two or three sorta being all of them small fruit, somewhat greener on the outside than the summer kindes; all of them very delicate and good in their due time; so some will not be fit to bee eaten when others are well-nigh spent, every of them outlesting another by a moseth or more.' But of the Autumn Bergamot we have no early record."

NAMES OF FRUITS (J. B.).—1, Beurré de Capisamont; 2, Louise Bome of Jersey; 3, Beurré Diel. (H. Handley).—1, King of the Pippins; 2, Domelow's Seedling; 3, Beauty of Kent; 4, Cellini; 5, Ribston Puppin; 6, Warner's King. We cannot name the others. (J. T.).—The Apple is Gloria Mandi, the Pear Beurré Clairgeau. In consequence of Dr. Hogg's absence, fruit eath by some other correspondents cannot be named this week. (F. M. L.).—The Pear is, we think, Beurré Clairgeau. The Apple we cannot name, it appears to be an imperfect specimen.

NAMES OF PLANTS (J. B.).—The specimen was insufficient for identification. We cannot undertake to name a plant from a single leaf, males it possesses some marked characters. (H. G. M.).—It is Queross coccines (the American Oak), and may be brighter another year. (Dar).—1, Salvia splendens; 2, Pteris serrulata; 3, Saxifraga sarmentoss.

THE HOME PARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

NITRATE OF SODA AND ITS USAGE AS A MANURE.

Thus is a substance which is every year becoming more extended in its application as manure. It is, however, a powerful stimulant to vegetation, and requires great care in its application, and may be said to be a good servant but a bad master. It is necessary, therefore, to use great caution and intelligent inquiry before its application can be ventured on with safety. At the same time it is fortunate that a great many experiments have been carried out which will enable the home farmer of the present day to commence using this manure with some confidence. It is our intention to illustrate its effects upon the various farm preducts, not only from our own practice, but also from the practice and theory of the most intelligent men of our time. The most eminent of the experimenters was first the late Mr. Pusey, who in 1852 was President of the Royal Agricultural Society of England, and who for some years acted as the editor of the Society's "Journal." Mr. J. B. Lawes, and also Dr. Voeleker have both contributed, together with many other men, by experiments and by expounding the chemical value of this menure, to bring it before the farmer in a manner which will enable him to use it under varying circumstances with safety and advantage as a fertiliser for the various productions of the farm. Artificial manures had been used so extensively, especially guano of different sorts, that it was feared at one time that the supply of this article would not be available for many more years; and at present, although it can be obtained, it is not se good or plentiful as it formerly was. It is fortunate, therefore, that nitrate of sods is now available to almost an unlimited extent.

It was in the year 1881, however, that nitrate of soda began to attract most attention, for a cargo imported realised £35 per ton. From that time the importations have greatly increased every year, so that the quantity for use at present is enormous. The production of nitrate of soda is almost exclusively confined to the province of Tarapaca in Peru, and chiefly in the pampas of Tamarugal, running north and south about eighty miles, and about twelve miles from the western shore. This vast plain, situated 3000 feet above the level of the sea, is at the foot of the gigantic Andes Mountains. The district is a rainless one, which is accounted for from the fact that the trade winds blowing unceasingly from east to west, and thus having to pass over the Andes, the air is thereby deprived of all its moisture. The salt exudes from the ground, and is in some places from 7 to 8 feet in depth. It is sometimes found quite pure, but when not so its impurities are extracted by dissolving in water and evaporating to dryness, either by the heat of the sum or by fuel. The chief port from which the nitrate has to be embarked is Iquique, a distance of ten miles as the crow flies from the nitre beds. Formerly

the nitrate was conveyed upon the backs of camels or mules to the port, which, together with the expense of purification, made the total cost of production excessive. Since then a railway has been constructed, and we are now enabled to obtain the nitrate at

a more reasonable price.

Nitrate of sods, however, requires judicious application both as to quantity and the time of usage, for instead of its proving a valuable manure it may prove under certain circumstances a serious injury to the various crops which it may have been the intention to improve. In order to show this matter in a practical manner we shall lay before the home farmer a number of experiments both of success and failure to illustrate our subject, at the same time giving reasons in detail for each. We will take Mr. Pusey's experiment first, who says, "My land being in good order, but the barley having been sown very early—viz., in February, it had suffered from the effects of unusually sharp frosts. A dressing of nitrate of soda was given of 42 ms. per acre, with twice the quantity of common salt. A strip of the land was left undressed. The barley crop soon recovered itself, and upon threshing the crop the undressed portion gave only 40 bushels; the top-dressed portion, however, yielded 47 bushels, an increase of 7 bushels per acre, the value of which was 26s., the cost of the top-dressing being only 6s. 4d., the result being therefore an advantage of 300 per cent." Another experiment between guano and nitrate of soda was tried in Windsor Great Park. The quantity used was 2 cwt. of Peruvian guano as compared with 2 cwt. of nitrate of sods, one experiment being on high undrained land and the other on low-lying meadow The result in each case proved favourable to the guano. This advantage, however, was most probably due to the fact that the heavy rains which prevailed at the time may have washed down the nitrate below the roots of the grass; nitrate of soda being so extremely soluble, requiring less than two parts of water to dissolve it. Experiments made by Mr. Hope of Fenton Barns an eminent Scotch agriculturist, however, confirmed the Windsor trial. He found that 90 lbs. of nitrate of sods and 180 lbs. of Peruvian guano as a top-dressing upon clover and rye grass gave better vian guano as a top-dressing upon clover and rye grass gave better results than by using nitrate alone or than double the quantity of guano by itself. Now the lesson taught here is that the nitrogen of the nitrate of soda required assistance from the phosphates supplied in the guano, and probably from the potseh contained as well. We know that in dry seasons a loss of ammonia has attended the application of guano, and the remainder has not been rendered soluble; and as upon grass land the guano cannot be harrowed in, it is better to use nitrate only, with the addition of soluble phosphates and, if required, potash. In dry seasons we know from our practice that such top-dressings of nitrate of soda are preferable to guano. are preferable to guano.

Mr. Pusey in one of his experiments with nitrate of soda as Mr. Pusey in one of his experiments with nitrate of soda as compared with guano as a top-dressing for wheat found the following results:—The undressed portions gave 21 bushels per acre; 2 cwt. of guano gave 24 bushels per acre, being an increase only of 3 bushels; 1 cwt. of nitrate of soda with the addition of common salt gave 25 bushels per acre. This, however, occurred in a dry summer, and the proportion of increase was hardly fair to the guano, but was one of the most successful applications of nitrate of sode area recorded. A valuable avarentment was made by Mr. of soda ever recorded. A valuable experiment was made by Mr. Pusey upon a sandy loam soil, because it proved a total failure as regards the autumnal sowing, whilst the spring dressing—consisting of 2 cwt. of nitrate with 4 cwt. of salt—gave an increase upon 2½ acres of 3½ quarters of grain, which, deducting the cost of manure, gave an increased advantage of £8. The autumn-sown manures evidently failed in consequence of the autumnal rains which prevailed at the time. Another comparison between the value of guano and nitrate was made by Mr. Hope in an experiment, with the following results:—1 cwt. of nitrate mixed with common sait gave 374 cwt. of straw and 58 bushels of wheat; 8 cwt. of guano gave 84 cwt. of straw and 49 bushels of wheat. The unmanured portion of the field gave 83 cwt. of straw and 89 bushels of wheat. In this case the cost of the grano exceeded that of the mitrate by 12s., yet the increase of grain from the nitrate was 4 bushels. A very successful practice of the use of nitrate of soda in the growth of mangolds is made by a home farmer whom we know. His plan is, after having prepared the land well and applied a liberal dressing of farmyard dung ridged-in on the baulk, as soon as the mangold plants are big enough to hoe he applies & cwt. of nitrate at the time of hoeing, and the same again sown broadcast at the second hoeing, about the same quantity of common salt being used with the nitrate at each application. This to our mind is capital farming, and insures, as far as manures can insure, an abundant crop of roots. A friend of ours on the first attempt to use nitrate of soda for his wheat sustained a loss rather than a profit, for he applied 2 cwt. of nitrate per acre as a top-dressing in the spring, and at the time the wheat was well out in ear it looked like yielding thirteen or fourteen sacks per acre; but heavy rains commencing on the 16th of June had the effect of lodging the erop, and it became very much blighted and only yielded a mode-rate crop of very thin and light grain. Now this is an instance of failure entirely because he did not know how to use the nitrate, for in case half the nitrate had been used with 2 cwt. of superphosphate and 2 or 3 bushels of common salt his crop would have

been stiff in the straw and free from blight in all probability. This failure, however, taught him a lesson which he was not slow to learn, for he has since succeeded well with nitrate in admixture with mineral manures and salt.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour .- This will now be very heavy, in consequence of the late seed time. Where, however, the wheat is sown after fallow or fallow crops much of the land intended for wheat cannot be sown, for it has been in some cases utterly impossible, particularly on strong loams, to make the naked fallow, or prepare the land in a clean state after fallow crops. We have lately been over strong land farms on the chalk hills as well as vale farms where the fallows have not been made, although sufficient horse and steam power have been used to have made clean fallows horse and steam power have been used to have made clean fallows in an ordinary season. In consequence the land wheat cannot be sown; but the land will probably be held over and tilled for barley in the spring, and should the weather be favourable at that time no doubt the barley crop will pay as well or better than late-sown wheat. In those cases where but little couch is left in bunches we prefer to fork it out previous to the sowing of wheat or any other crop, as we find that the first expense is always the least, and particularly when a little hand labour saves the expense of costly horse labour. The variety of wheat we have recommended on the heat and early day soils this year is the recommended on the best and early dry soils this year is the Essex rough chaff upon lea ground in high condition, and the best old wheat will be found much surer to vegetate than the produce of last harvest, which did not ripen properly. This sort of wheat grows very short and stiff in the straw, even on the best wheat grows very short and shift in the straw, even on the best soils and under the highest cultivation. About 23 bushels of seed will be sufficient until the middle of November, after which time 3 bushels will be none too much, particularly on lea ground, where the slugs are likely to attack the plants, and it is this year perhaps better to sow rather late than otherwise, with the view of avoiding these enemies. As, however, the potato land will now be ready for seeding it will be better to sow this land before the clover lea, and to dress this with 3 cwt. of Peruvian guano, the the ground. It is a practice which we can recommend to the home farmer after the lat of November to plough and sow the land simultaneously—that is, on the same day, for in case of waiting to sow a whole field rain or frost is pretty certain to intervene, either of which prevents the land being seeded in such a good state as when sown after the plough. On the potato land we recommend the Morton's red-strawed white wheat, or in case the climate is not adapted for white varieties we sow Nursery or Golden Drop, as either of the varieties are sure to stand the winter better than white varieties, and in case of being injured and suffering by loss of plant they will tiller so much as to make up almost any deficiencies.

Hand Labour.—This will still be employed in spreading manure

on the land for ploughing in for wheat, also in making out the water furrows after sowing the wheat. On all strong flat-lying land there will be some work of this kind, and it is of importance, because the water furrows should always be made several inches deeper than the land furrows, and when they are thus made they do not so quickly get filled, or partly filled, with the grit which washes into them. Where there is not a good fall for the water the fall should be made by taking out the earth deeper where required. All the pastures on which cattle have been fed during the summer should have the bunches of grass and rushes, &c., cut over with the scythe preparatory to the trenching being done. The water meadows will now require to be trenched, making out both the carriers and drawing trenches with care, as they will be put under irrigation soon, and the sooner the better. The plashing and laying of hedges, making out ditches, and banking will be the first work after wheat-sowing is completed; the a proper shape by keeping the centre of the driftway highest, and remove all accumulations at the outside by making out the sides or water tables. These materials will be useful if carried to heap as compost for various purposes, such as affording earth for placing at the bottoms of pigsties, cattle boxes, cattle sheds, and yards after it has been mellowed in heap for five or six months. The taking-up and storing root crops will still be going on; and when the horse labour is required, particularly in wheat-sowing, the roots may be heaped in the field in a temporary manner, and subsequently carted away to heap or store. The odd horse will now be required in daily carting some cabbages or rabi on to the pastures for the dairy cows and young stock, as the grass is now both short and stale. The shepherds will now be required to look to the sheep's feet daily when they are suffering from lameness, and it prevails to a great extent in various counties and districts, especially where the land is wet and cold. We hear that th

not quite free from lameness, because this kind of stock always suffer from the foot rot more or less in the winter months,

AUTUMN ROOT SHOWS.

SEVERAL of the larger seed firms stated in their spring catalogues that as usual they should hold their autumnal root shows and give their usual prizes; but I find one firm has already given notice that on account of the bad season their show will not be held this autumn, and I understand some of the others are undecided and wavering. I think this should not be so. If the shows are not held many intending exhibitors will be disappointed. I maintain when customers are induced to buy seeds from catalogues issued in the spring, and, no conditions attached, stating certain prizes will be given for exhibits at their autumn root shows, it ought to be carried out let the season be good or bad; all exhibitors will have the same chance, and have to contend against the season. I have not yet heard or seen any schedule of prizes for the autumn root shows, and if they are to be held it is time they were out.—NEMO.

EXHIBITION BASKETS.

Many are the risks to which poultry are liable in their journeys to and from exhibitions. We can remember when they were more, and when the method in which they were sent must have been extremely troublesome to those in charge of shows. Formerly rough open-work hampers were frequently to be seen with valuable birds in them addressed to exhibitions; the wind whistled through them, while the poor birds were left for hours exposed to all the draughts of railway stations. They were of every conceivable form and size, generally rounded at the top, so that one basket placed on another would be sure to roll off; or sometimes they had no lids, and were simply covered over with canvas or sacking; in this case a heavy weight on the top always endangered the lives of their occupants, and a troublesome little job awaited those who, at the repacking of the birds, had to sew up the coverings. Such awkward and dangerous conveyances are now generally discarded save at rustic local shows. A great uniformity of baskets has of late been observable, insomuch that we always find difficulty in distinguishing our own at the close of a show. Nearly all careful exhibitors send their birds in much the same kind of baskets, of open wickerwork, round, and well lined and covered. In such baskets tails are not broken, and a slight tumble is less likely to do serious damage than when there are angular corners. They have, however, their drawbacks; among others, they are easily rolled. We heard not long ago, on the highest authority, that at the Clapham Junction station, just before or after a Crystal Palace show, they were trundled down the platform by dozens like barrels. We have, when going to a show in the eastern counties, seen a high covered van arrive at Bishopsgate with a perfect stack of them strapped over the top on their sides. There are risks, too, from the thin coverings not fully protecting the birds from wet or anything accidentally upset over them. A celebrated cup bird of ours once had to be sent away from the Crystal Palace o

The Poultry Club has, as we lately announced, offered liberal prizes for the best exhibition basket, to be competed for at the Crystal Palace Show. We do not pretend to describe the perfect basket, or to forestall the ingenuity of the basket makers. We only wish to point out some of the disadvantages of the common type of basket, in the hope that they may be remedied. There is a handle difficulty. We have had baskets with handles on the top, then they cannot well be packed one over another. We have had them with handles on the sides; these the porters seize, throwing the baskets on their sides. We have had them without handles at all, when they are rolled or lifted by the top wickerwork till it breaks. We are inclined to think that tops should be made peculiarly strong, and holes left on each side of the centre cross wicker bar, into which the hand can be thrust as into a handle, but without the inconvenience of a handle rising above the top level. We have before us a circular issued by the Poultry Club concerning this competition of baskets. In it we read, "The Judges will be instructed to take into consideration, in awarding the prizes, the strength, lightness, durability, and facility of transit of the baskets." We trust that with these hints basket makers will not fail to produce something really novel and practically useful at

the Palace. In these days exhibitors are very properly allowed to send several birds in divided baskets to almost every show; this widens the field for ingenuity in their construction. If exhibitions are necessary for the improvement of poultry, or if we promote them solely for our own amusement, we are bound as fanciers, to do our best that the birds which we exhibit may suffer as little discomfort as possible in their travels.—C.

THE POULTRY CLUB.

A COMMITTEE meeting of the Poultry Club was held at Oxford during the Show in a room kindly lent by the Committee of the Show. The Rev. G. Raynor, Hazeleigh Rectory, Malcon, was elected a member. The further consideration of the disqualification at Ross was postponed till the next Committee meeting. The disqualifications had been read from the Secretaries and Judge of the Show and from the owners of the drake the following resolution was passed:—"The Committee of the Poultry Club accept Mesers. Chadwicks' explanation of the object with which the wing of their drake disqualified at the Hemel Hempstead Show was cut, and entirely exonerate them from all frandulent intention in the matter; at the same time the Committee advise Messrs. Chadwick not to show birds whose plumage has been trimmed for any purpose whatever." It was agreed that the general meeting shall if possible be held at the Crystal Palace Hotel at 4.80 P.M. on Tuesday, November 18th.

PRIORLY COMPREY versus RABBITS.—At page 820 information as to whether hares and rabbits eat this plant or not is asked for. Last spring I planted a quantity of it here in sand about the seashore where hares and rabbits are abundant, and although it is now a considerable height they have not eaten a leaf of it.—A KITCHEN GARDENER.

VARIETIES.

At the Council Meeting of the Bath and West of England Society and Southern Counties Association, held on the 28th ult at the Grand Hotel, Bristol, Sir J. T. B. Duckworth, Bart, in the chair, it was resolved that the Exhibition at Worcester next year shall commence on Wednesday, June 2nd, and close on Monday, June 7th. The stock prize sheet was settled upon the same scale as that at Exeter, but the list of prizes offered for poultry was altered to make the single-bird system uniform throughout. A communication was read from the Hon. Local Secretary at Worcester, enclosing a copy of a letter from the proprietor of Berrow's Worcester Journal, offering a donation of one hundred guineas, to be distributed as special prizes to book fide tenant farmers of Worcestershire for excellence in agriculture, as premiums for cattle, &c., or in such other way as the Committee of the Worcester Society may think best calculated to promote a friendly and beneficial rivalry amongst the agriculturists of the county. The reading of this letter was followed by considerable applause, and a fortnight's grace was allowed to the Worcester Local Committee for the preparation of their special prize list. In response to communications received from the Secretary of the Tunbridge Wells Farmers' Club, a deputation was appointed to visit that town for the purpose of inspecting a site which has been offered for the meeting of 1881.

— The Dorset County Poultry, Pigeon, and Cage Bird Show will be held at Dorchester on the 14th and 15th January,

1880. Entries close January 1st.

— WE learn from statistics published by the Italian Government that the value of eggs exported from Italy during the late financial year amounted to no less a sum than 9,000,000 lire!

The fancy for highly-bred stock seems spreading fast over the civilised world. Some years ago agricultural shows were started in North Italy, where we should expect them to thrive. In truly continental style the prize oxen decorated with ribbons were led in procession round the old town of Aosta headed by a cannot the cathedral! We now learn that a show has just been held so far south as in the sleepy Neapolitan town of Gaserts. An exhibition of poultry was included in this programme.

— MESSER, JAMES CARTER & Co., High Holborn, London, and cavelers work will see that their annual Show of farm and cavelers work will

MESSES. JAMES CARTER & Co., High Holborn, London, announce that their annual Show of farm and garden roots will be held in the Agricultural Hall, Islington, on November 21st. Five cups, value £10 each, are provided for Swedes and mangold wurtzel, and many prizes for various other farm roots; also for twelve dishes of vegetables, and potatoes and onions grown in gardens. Messrs. James Gibbs & Co., and Messrs. Ohlendorff and Co., offer silver cups at the same Show for roots (the products of Carter's seeds) grown by the aid of their manures. The latest day for receiving entries for the Show is November 18th. The chief prizes can be had in money or silver plate at the option of the winners. The number of the classes in the schedule is twenty-three, and the value of the prizes offered exceeds £130.

— FLIGHT OF WOODOOKS.—Numerous flights of woodcocks are reported as passing over Jersey from the north, making
their way to the warmer climate of France. Many have been

shot on their passage, and are found to be large and plump birds. The early departure, some few weeks before the usual time, is

said to denote an early and severe winter.

THE SALE OF MILK.—The "barn gallon" is an institution to which the attention of "informers" may be usefully directed. What it accurately is no man can tell, and the milkseller is apt to What it accurately is no man can tell, and the milkseller is apt to make shipwreck in the fog. One thing, however, is certain—that it comes exactly within that provision of the Weights and Measures Act, which specifies certain imperial measures alone receiving legal sanction. A "barn gallon" is said to be two imperial gallons and a pint; but it is the town buyer who provides the churns in which the milk is delivered to him, and the churn makers say that the "trade" require measures which are so many makers say that the "trade" require measures which are so many barn gallons plus an indefinite added space, capable of considerably enlarging the contents beyond the declared multiple of 17 pints. Why should not milk, like other goods, be sold by weight? The quality is cared for by the legislature, and inspectors are down upon anyone who adds water to his milk. The quantities a market for improving a Caretter of the content of the caretter of tity is quite as much a matter for inspection.—(Agricultural Gazette.)

BEES.

[A lecture delivered before the Wimbledon Gardeners' Association by Mr. Ollerhead.]

Amonger the many pursuits that one could be engaged in during leisure moments, few are more interesting or lucrative than the management of bees. To search into the mysteries of the when management of bees. To search into the hysteries of the hive, watch the queen or mother bee laying her eggs, her attend-ants following her, the progress of the larve, the formation of cells, particularly the queen's, the storing of honey, and the various other work conducted with such wonderful regularity and discipline, when fully explained cannot fail to interest. On the other hand, the profits accruing from a few hives of bees in a favourable season when properly managed are astonishing. Mr. Pettigrew in his most valuable "Handy Book on Bees" tell us that his own profits altogether from 1870 to 1874 were upwards of £220, after deducting an annual expenditure of 10s. per hive. It must not, however, be expected that this is realised without a certain percentage of care and trouble. To suppose that simply because you procure a hive of bees and set it on a stand in the garden that your care and outlay is at an end, and that nothing but profit must follow, is quite erroneous. It is true that in favourable seasons the bees will take care of themselves to a very great exseason like bees will take care of themselves to a very great extent and gather in stores of honey. Such is not the case in a season like the past, because there has been very little honey or nectar in the flowers, and the excessively wet weather has prevented the bees collecting what little there was to be obtained.

vented the bees collecting what little there was to be obtained. I am prepared to hear sad news from the bee-keeping community next spring. Depend upon it, only they who have paid unremitting attention to their bees this year will be able to commence next season with advantage. Feeding, feeding, feeding all the year or nearly so has been the principal work in the apiary during the year 1879; in fact I can hardly tell you to what extent I have been feeding the bees unless I look up my memorandums

very carefully.

very carefully.

Last autumn I carefully prepared twenty hives for the winter—viz., four Pettigrew's, three Neighbours' cottage hives, two Stewartons, five Woodbury's, two Carr-Stewartons, and four double Neighbours'. The latter were Neighbours' cottage hives—hives with the crown board knocked out, and the super cover attached to the body hive so as to make a good-sized one, as I am persuaded from experience that all Neighbours' small cottage hives are too small, and only adapted for selling small swarms for profit. The whole twenty hives referred to passed through the winter safely, and strong, except one, a Stewarton, which on being examined early in March was found very weak. This was united to a Neighbour hive close by. The long cold spring was very unfavourable for breeding, and at the end of April the bees were no stronger than they were early in March. This was particularly noticeable in the wooden hives, although the crown boards were removed and the hives well covered up with housemaids' flannel and other warm the hives well covered up with housemaids' flannel and other warm I may also state that bees as a rule in straw skeps work earlier and later than those in wooden hives

This year I have had to drive two stocks infested with foul brood, the cause of which I attributed to the vicissitudes of temperature. A few warm days caused the bees to expand and cover the combs. Stimulated by a little slow feeding the queens exercised their laying powers; the eggs were set and larvæ were hatched when the cold wet weather caused them to huddle up into closer quarters, leaving portions of the brood uncovered, causing a chill, followed by death, putrefaction, and foul brood. We are told that salicylic acid if putrefaction, and foul brood. We are told that salicylic acid if properly applied is a safe and certain cure, but I think the best cure is to drive the bees into a clean empty hive, feed them for a couple of days, drive again and unite to a healthy stock, and scald the hive they were in two days in readiness for further use. I have generally had my hives free from foul brood by keeping clean combs in them, and by not keeping old stocks too long. I have many times cut out small portions of infected comb, and thus prevented further arread of disease. I never wintered such stocks, but united them apread of disease. I never wintered such stocks, but united them to others in the autumn or fed them with sugar.

The bees in this neighbourhood could not obtain food sufficient to keep them in existence this year until the limes came into flower, then there was a glut for a few days; and on July 81st, the limes being over or nearly so, we took them a few miles out to the heather; but the continual wet weather prevented them gathering what little nectar there was in the flowers, and after waiting patiently for a favourable turn in the weather, but without realisation of the state ing it, we fetched them home September the 9th much lighter than when we took them away. We examined them thoroughly, and found a very little brood in the straw skeps and none at all in the wooden hives.

Our next task was to unite some of the stocks to swarms, destroy the old queens, and prepare them for winter by liberal feeding until each stock has sufficient food to last them until next March. Thus we have prepared and reduced the number of our hives to fifteen. I may also here state that I fed the bees very slowly until nearly the middle of this month so as to secure a late hatch of bees, as on these depend the strength of the hives next year. As I must on these depend the strength of the nives next year. As I must remind you that it has been ascertained that no worker bee lives longer than five months at any period of the year, and in the height of the busy season their existence is much shorter, also that during the winter season little or no breeding in the hive is going on to keep up the population. Thus the old bees keep dying off, and there is none hatching out to take their places, and this is why a hive strong in bees in autumn becomes much reduced by spring. In fact I know of several instances where hives strong in bees last autumn passed through the winter safely, but the bees died in April. This I attribute to the want of slow feeding last died in April. This I attribute to the want of slow feeding last autumn to secure a late hatch of bees, and also to the want of feeding early in March and onwards, keeping the hives well wrapped up and cosy to secure early brood in spring. If the queen finds no food coming into the hive she will cease to lay, and the workers finding a famine imminent will cast the young out of their cells. All bee-keepers that wish to prosper will not fail to pay special attention to this important point.

attention to this important point.

Thus you see the art of bee-keeping does not merely consist of buying a hive of bees and putting them in the garden to look after themselves, but there is care, attention, and a little know-ledge required if you wish to succeed. There is much superstition existing relative to bees. Some say they dare not go near them as they would be sure to get stung. Well, I would not advise any timid person to approach a hive without a veil, and then under

as they would be sure to get stung. Well, I would not advise any timid person to approach a hive without a veil, and then under proper tuition the most timid one may overcome and do anything they wish with their bees. Other people will tell you if the bees master dies, and you do not tell the bees or rap the hive and put a black rag on it, the bees will all die, but this is ridiculous. The fact is the bees die from neglect, in some instances from want of judicious feeding, while in others the bees take care of themselves till foul brood seizes a colony. This is pillaged by its neighbour hives. The disease is spread until they are all contaminated, and ultimately succumb to the pestilence, and then the would-be bee prophets tell you, "Oh! I told you would lose them," &c.

If you wish to enter into bee-keeping and know nothing about them, consult a friend or neighbour that does, and obtain his advice and assistance in buying a hive. The price will of course depend on circumstances, such as the time of year and the kind of hive the bees are in, and also the locality. You could hardly expect to obtain a hive in Regent Street at the same price as you would pay on Salisbury Plains or the wilds of Dartmoor. If you ask what kind of bees you should buy, I answer, Blacks of course. After many careful trials in testing the superiority of the Ligurian over the black bees I have come to the conclusion that Ligurians are fancy bees at a fancy price. My last experiment was made several years ago, which resulted as follows:—Two swarms as near 7 ibs. each as possible were placed into two hives exactly the same make and about 5 yards from each other. They were fed in exactly the same proportions and treated alike in every way until the end of the following season, when the stock hives with their swarms were weighed. Contents of Ligurian stock hive 71 ibs., first swarm 70 ibs., second swarm 21 ibs., total 162 ibs. Contents of black bees' stock hive 59 ibs., first swarm 78 ibs., second swarm 82 ibs., total 164 ibs.; credit to the 70 fbs., second swarm 21 fbs., total 162 fbs. Contents of black bees' stock hive 59 fbs., first swarm 78 fbs., second swarm 82 fbs., total 164 fbs.; credit to the black bees 2 fbs. Some people will tell you that the Ligurians work earlier and later, wet as well as dry weather, are more prolific, and have a host of other good properties. Well, such may be the case, but I for one so far have failed to realise them. I must confess that I like to see the Ligurians in an apiary and paid 11s. for one last June, but it was not because I expected to realise any advantage from her, it was merely for the sake of having a pure one in the apiary.

We now come to the question of hives. A great diversity of opinion exists as to which is the best hive to use. The old straw

opinion exists as to which is the best hive to use. The old straw skep, the 20-inch Pettigrew, the cottage Neighbour, the Woodbury, and Carr-Stewarton, are each good in their way, but to my mind the best hive for quantity of honey, either in the comb or in supers, is the Pettigrew. The hive itself has capacity for a prodigious quantity of honey, while sectional or other supers may be piled on the crown to any extent desirable. Neighbours' Crystal Palace straw skep is also a capital hive. Of the wooden hives in use none pleases me so well as the old Woodbury; from it you can obtain honey in the frames or in side or top supers.

These three are the only hives I would recommend to anyone; but all apiarians as a rule have their pet hives, particularly the manufacturers. I was highly amused when visiting the Show at Kilburn by a vendor offering to show me the only hive that had produced British honey in the Show. Now, mind, it was the hive that had produced it. I of course availed myself of the opportunity, and saw what I considered was two Woodburys piled one on the other with a place and the state of the with a place of the course of the state o on the other, with excluder zinc for side and top supers, and a few on the other, with excluder zinc for side and top supers, and a few other complications of the manufacturer completed the wonderful live for which the modest sum of two guineas was asked. The zinc had round holes in it, and I inquired if he never found any bees die inside the zinc. "Oh, no!" was the reply. I told him my experience was the reverse. He attributed it to the way it was put on; bat I can only say they will die put it on how you may, and the living bees cannot carry the dead through it. I fully expected he had Ligurian bees, but it turned out he had fifty hives of black bees. Having satisfied him that the bees, not the hive, gathered the honey, I inquired what they gathered it off. "Forty acres of lucerne," was the reply; "but mind you," says he, "it's no use unless you put two swarms in one hive, fill your hive with bees, and then you will obtain honey." This reminds me of a man who boasted to me of a wonderful super of honey he took last year. "Was this the produce of one swarm?" "One hive," says he. "But were they the offspring or swarm of one legitimate hive or stock of bees?" "Ah, well, no, I cannot say that." "Tell me the truth, now; how many swarms did you put together?" "Well, I wanted to do something grand, and I don't intend to tell everybody, but I put seven swarms together." "Oh, well, if you cut up the super into seven it is not much after all." So you see it is not they that cry the loudest that have the most to sell other complications of the manufacturer completed the wonderful So you see it is not they that cry the loudest that have the most to sell.

There is no doubt that bees will do well in almost any hive provided they are properly managed, but the fewer obstructions you have in a hive the better it is to my way of thinking. We have heard of the wonderful feats of the "Renferwhenire Beekeeper" with his Stewarton hives, but I can only say they are no better than any other; in fact, I do not like them so well as a Woodbury. I have three sets of boxes and supers now never been used, and will be very pleased to sell them for what they cost for making—not charging for the materials. I have visited every show of the British Bee-keepers' Association, and have so far failed to find any hives better adapted for the profitable management of bees than the Pettigrew, Crystal Palace straw skep, and the common Woodbury, and, I think, it will be a long time before we find better in the market. I took 110 lbs. of honey out of a Pettigrew three years ago, and 97 lbs. out of another, There is no doubt that bees will do well in almost any hive out of a Pettigrew three years ago, and 97 lbs. out of another, which was considerably more than the returns from any of the other hives on the same ground and under the same treatment.

One word now as to supers. Doubtless, the worst kind of super for bees is a glass one, and the one that they take to most freely is made of straw. Supers are made in a great variety of shapes and forms. The best side box, super, or section that has yet come under my notice is one made in America, and was exhibited by Mr. Newman of Chicago, at Kilburn and South Kensington this year. They are all in one piece, and so contrived that a bit of guide can be run in them and then folded so as to form a section about 4 inches square by 3 inches in width, the whole held together by one small French nail, a bit of gummed paper, glue, or anything of the kind, and are admirably adapted for working in anything of the kind, and are admirably adapted for working in frame hives. Another good form of section is Abbott's; there is some filled with honey, others empty. These may be used either inside the hive or as supers on the top, with bits of tin to keep them straight. These are very good supers in their way, I have used many of them. There is also Neighbours' Crystal Palace used many of them. There is also Neighbours' Crystal Palace prize divisional super, but I do not like it at all. The bees do not always build straight in them, so that when they are cut through you break the crooked combs and so make the honey run or "bleed," as you will see in this super before you. The comb is not straight, it was put on the hive with guides just as received from Neighbours of Holborn.

At the close of the address Mr. Ollerhead submitted examples of the hives he had referred to, explaining their essential features, and pointing out the advantages and disadvantages pertaining to them. He also submitted the various appliances employed in the them. He also submitted the various appliances employed in the apiary, including the different articles for feeding bees, guide comb, queen cages and mode of using them, and gave examples of supering and of unting stocks. Supers of honey of faultless quality were further placed before the meeting, also imperfect supers, and some pieces of comb containing foul brood were also handed round for examination. Much attention was paid to the address, and the various object lessons at the close of it, and Mr. Ollerhead was warmly thanked for his interesting and instructive leading. lecture.

OUR LETTER BOX.

PERIN AND CAYUGA DICKS (N. E.).—These an wer admirably for domestic purposes; both sorts are very hardy and cater well for themselves. Pekins surpass all other Decks as keyers, and (keynes: mearly as good, as to appearance Pekins are fine and nobe-lon-ting irds. Cayugas have a lovely green gloss, and are when in high condition most attractive. We

know a flock of them which live in the hardiest way in a small park in Berkshire and are found very prolific. Their condition and plumage is just at this season very fine, and next to the wild Maliard we consider them the hest Ducks for the table.

best Ducks for the table.

Langsham Fowls (Idem).—We cannot pretend to give the points of Langshams, for their admirers are not consistent as to what point they desire. We believe the breed to be hardy and profific and suited to your requirements, though for table fowls we should not select an Asiatic breed. In spite of all said to the contrary by the enthusiastic admirers of Langshams, we believe them to be nearly allied to Cochins. All this family of fowls is wont to put more firsh on to the legs than on to the breast.

snams, we believe them to be hearly anded to commiss, we have to put more flesh on to the legs than on to the breast.

SMALL nersus LARGE FARMS (L. P.).—Small farms either in France, Belgium, or England, will pay better and yield more rent to the owner than larger farms, but they must be situated near to the large towns or railway stations, and used for the growth of vegetables, fruit, and other gastlen produce; it could not answer in England to use small farms for ordinary farming such as growth of cereals and roots for feeding fat cattle or sheep, but upon some small farms a portion under spade culture and some in pasture. Milk-selling may answer near to towns. It is, however, a question so intimately connected with soil, situation, and aspect, that it would not answer in general to divide the large farms into those of twelve to fifteen or twenty acres, because it would necessitate cottages and farm steading being built. The small occupations answer well near towns or stations, and let readily from 40x to 80x per acre with house and buildings; but we have not the population which have been accustomed to it to occupy small farms like France or Belgiumi, because theirs has been under such a system from time immemorial, the some successing the father often from generation to generation. If offered in this country small farms would find tenants in such situations as above named.

FREDING BEISG (Basy).—As the weather is mild in your district you had

FEEDING BEES (Best).—As the weather is mild in your district you had better continue feeding the hive for another week, when your letter shall be answered more fully.

REMARKS.

REMARKS.

29th.—Dull dark day, drizzling rain; fair evening.

30th.—Overcast and dull but dry day, rather windy.

31st.—Cloudy generally, glimpse of sunshine at 2 P.M.; moonlight night.

November 1st.—Slight rain in early morning, fine after 9 A.M., susshine at 1.30 P.M., cloudy after 3 P.M., rain at 5 P.M.; damp evening.

2nd.—Fine bright day, very cold wind; starlight evening.

3rd.—Cool and cloudy, drizzle in early morning, bright sunshine at intervals; alight rain 10 P.M.

4th.—Cool, cloudy, but fair.

Another dry week, and considerably cooler.—G. J. Symons.

COVENT GARDEN MARKET .- NOVEMBER 5.

LARGE supplies of American Apples still reach us, but samples are generally inferior though prices are good. Hothouse Grapes and Pines are in good demand, the absence of St. Michael's fruit causing the latter to be in

From observations taken near London during forty-three years, the average day temperature of the week is 48.7°; and its night more sale.

OVERCROPPING.

MALL fruit, poor in colour, deficient in flavour, often failing to come to full maturity; barrenness, debility, premature decay. Such are some of the lamentable results of overcropping Grape Vines and fruit trees-results so patent, evils so deplorable, but all of which might be avoided by the exercise of ordinary prudence and forbearance. We are all too prone to take things for granted. Inquiry into cause and effect is not half frequent or persistent enough, and yet it is manifest that without such

inquiry our work and its results must inevitably be

beset by a most unpleasant uncertainty.

When young fruit is thickly set upon a Peach tree no doubt it requires a certain amount of resolution to remove two-thirds of it; when a Grape Vine has a couple of shoots on the same spur, each with a young bunch of fruit extra-ordinary in size and promise, it seems a positive shame to cut off one of them, and yet in both cases neglecting to cut off and thin is running counter to the dictates of common sense and the stern teaching of experience. We may go further and assert that it is positive folly; so also is an overcrop of branches — crowded growth inducing disease, sterility, and under-sized fruit. Depend upon it enough space for a free admission of air and sunshine among branch, foliage, and fruit none of us can afford to despise.

To probe the evil more deeply, and by way of example, let us take the common case of a Peach tree in a state of exhaustion from overcropping, or rather half a dozen trees, for it does not affect every tree to the same extent. Some, though barkbound and weakly, may yet present an appearance of tolerable health, and display a tendency to grow and bear fruit; others have a sparse clothing of small foliage, but make no appreciable growth; others have sickly foliage and many dead branches, and are evidently hastening to premature decay. Now, at various times I have had to treat many such trees, and have invariably found them easily cured, if the branches are sound, by cutting away the entire head of the tree to within a couple of feet of its base, renovating and draining the border if necessary: thereby inducing a young growth of such vigour as to reach the top of an ordinary garden wall in three years, so that in four years it is again a full-sized tree in full bearing. Great as is the vitality of a Peach tree it is wrong to tax it so severely, and while showing the remedy for debility one must deplore and condemn the bad treatment that has

The nature of a Grape Vine is much more elastic. an exhausted Vine may be brought into a robust and fertile condition in a year or two by a judicious use of the pruning knife among its branches and a fresh supply of rich soil for its roots has repeatedly been shown in these pages. Let me add a word of caution about Vines in pots, which now have such an important part in early forcing that a blunder proves costly in the truest sense of the word. Never attempt overcropping Vines in pots. From four to

attempt to ripen more the fruit will certainly be undersized, and most likely shanking will attack the bunches with more or less severity. I learnt this to my cost a good many years ago when trying to ripen from eight to twelve bunches on some very strong canes. "You will never do it," said an experienced old Grape-grower. "At any rate I'll try hard," said I. But despite all my efforts, shanking attacked them so badly that hardly any of the bunches were presentable. The lesson was a severe one, and withal most useful in carrying conviction to my mind that over-cropping was a cause of shanking, and might be expected to induce it also in Vines established in a border.—EDWARD LUCKHURST.

ROSE CULTURE.

THE season is now at hand for transplanting Rose trees, and a few practical remarks may prove useful to amateurs and others. He who desires to form or extend a Rose arden must now make his arrangements for planting. the case of forming a new rosery the first question is, Where shall we find the best situation? The Rose must have a free circulation of air; it must be both exposed and sheltered, and have both sunshine and shade. The centre of the rosery must be open and surrounded by a protecting screen, so arranged that a large proportion of the trees will have the benefit of the sun during the fore part of the day. This can be effected by extending the garden from north to south, thus making it of an oblong or semicircular form. The northern fence must be tall and dense; the western should be tall, but not necessarily so dense as the northern; the eastern such as will check cold cutting winds, but not one ray of sunshine; the southern end requires some slight screen, such as a low bank, to break off rough winds which occasionally blow from that quarter. The surrounding screen should be masses of evergreens, such as Rhododendrons, Hollies, Yews, Berberries, &c.

We will now speak about soil. Roses may be grown in almost any ordinary garden soil if they have such a position as I have endeavoured to describe. An inferior cultivator, whether his inferiority is caused by want of knowledge or want of industry, is always snarling at his soil. Should the ground selected for the rosery be a cold adhesive clay the first thing to do is to drain it well 4 feet deep, with a good fall. When water stagnates around the roots of plants they cannot receive the air and warmth which are alike essential to their health. Trench the ground and make it as porous and friable as possible. Burnt clay, lime, or vegetable matter will considerably alter its texture and improve its quality. We have found burnt clay to be the most advantageous. The application of burnt clay renders the soil less compact, less tenacious, and less retentive of moisture. On the other hand, a light porous loam can be improved by intermixing stronger and more tenacious soil after the ground is drained. Then comes the manure. Farmyard manure should be employed very liberally. The degree of decomposition to which farmyard manure should arrive before it can be deemed a profitable manure greatly six good bunches should be the maximum number; if you depends on the nature or texture of the soil. Heavy clayey

NO. 1634.-VOL. LXII., OLD SERIES.

NO. 972.-VOL. XXXVIL, NEW SERIES.

soils may receive less decomposed manure than more pulverised soils would require.

Planting should be brought to a close by the end of November if possible. When planting, all tap roots should be removed and any roots of great length shortened. Roses are frequently planted much deeper than is necessary, in many cases to save the trouble of staking. They should be planted just deep enough to be firm in the soil. After planting cover the surface over with a stratum of manure, both as a protection and also to feed the roots. In the case of established plants the season when manure is applied is an important circumstance. For instance, in spring and summer the object is to produce an immediate effect; therefore the manure should be more completely decomposed than is otherwise necessary when laid on in the autumn. Liquid manure from the farmyard is very beneficial, but let the reader remember the true rule of appli-cation—viz., weak and often. We always give two applications of liquid manure during the winter-in December and January. Bones are largely used by some cultivators, and we have a very high admiration of the bone as a manure. Nevertheless bones are not the manure for Roses, and the same may be said of guano; its influence is quickly evident in size and brightness of foliage, but the flowers, so far as our experiments show, derive no advantage, and even on the leaf the effect is transitory. After careful experiments with various manures we have found nothing so effectual as farmyard manure, which is the best for the Rose's health and beauty.

We now commence shortening by one-fourth the longest shoots of our established plants, thus preventing the rough winds from loosening the hold which the trees have upon the These cuttings are inserted in a sheltered place and protected by handglasses: most of them will be rooted by April, when they are potted and gradually hardened off, and planted out in May. March is the month of our final pruning, except Noisettes and Teas, which are left until April. As there are many who fail to grow the Maréchal Niel Rose well, I may here add for their interest that the old Gloire de Dijon is the best stock on which to bud it that I am acquainted with, and the Banksian Rose is a most genial stock for the Marechal; and if any of my readers are the happy proprietors of the former under glass, by all means bud the latter upon it. As the Maréchal is not perfectly hardy it requires to be well protected at the roots by manure in the winter, and even the upper growths must be screened if the weather be very severe. In preference to drawing out a list of the best Roses (as lists of good Roses appear in our Journal frequently) I will endeavour to point out the properties that a perfect Rose must possess. First, beauty of form—petals abundant and of good substance, regularly and gracefully disposed within a circular symmetrical outline; secondly, beauty of colour—brilliancy, purity, and endurance.—JOHN LLOYD JONES.

FRUIT TREES IN PERFORATED POTS.

In a notice of the nurseries at Sawbridgeworth published on pp. 433-4, vol. xxxvi., reference is made to Mr. T. F. Rivers' mode of growing Pear and Peach trees in perforated pots. The trees were then laden with blossom; they have since perfected their fruit, and the weight and value of the crops prove the real usefulness of the system of culture in question.

The principle on which this mode of culture is founded is that fruit trees produce two distinct phases of growth under ground as well as above it, the one being annual, the other permanent. Above ground the foliage is the annual portion of the trees; and corresponding to the growth of the leaves on the stems are masses of small fibres produced by the roots. These leaves and fibres are produced and perish contemporaneously—the one cannot exist without the other. They have done their work in the autumn of supporting the crop and increasing the size and number of the branches of the trees, hence decay. With the production of fresh leaves new fibrous roots are formed to maintain the health and vigour of the trees. These roots, being only wanted in summer, are by this system of culture removed in the autumn, and masses of new roots are encouraged and new feeding ground provided to supply them with sustenance so that it can be readily and profitably appropriated. All gardeners know the benefit of top-dressings is, adding fresh food to the surface of the pots in which fruit trees ere grown; but no system of top-dressing can equal Mr. Rivers' latest mode of supporting the trees, at the same time saving a great amount of labour which must be expended in watering when the pots are exposed to the air.

Pear trees only about 3 feet high in 8 and 10-inch pots are some of them bearing from twelve to twenty-four fruits, far excelling in size and quality those produced by trees in the open. In fact few trees that could not be protected in the spring have produced any fruit at all, and most of what little there is, is cracked and nearly worthless. The pot trees are easily protected, either by being placed under glass, or laid down closely together and covered with mats during severe weather. This past, the pots are plunged in good soil, of which new roots issuing from the perforations take possession, deriving support for the swelling crop. Such trees by the sides of walks are both ornamental and useful, and are certainly not difficult to grow nor need more time expending on them than is requisite in growing Chrysanthemums.

But perhaps the advantages of the system are more strikingly exemplified by a number of Peach trees grown in a very light unheated span-roofed house. In this house is a central path and two side borders wide enough for two rows of trees in each. These trees in 10-inch pots have produced from three to five dozen Peaches each of the first quality. The fruit being gathered and the leaves changing, the roots issuing from the sides of the pots are of no further use, and were being cut off at the time of my visit a few days ago and the pots replunged in the borders, which were enriched with fresh soil and manure for their reception. No one seeing the pots lifted out of their summer quarters could fail being astonished at the dense moplike masses of fibrous roots attached to them. The greater portion of these, like the leaves, being annual, were shrivelling, and the whole were cut off within about 2 inches of the pots. There were five times more feeding roots outside the pots than could possibly have been produced in them; and the trees told how well they had done their work—short, hard, healthy growths and prominent buds ready for producing full crops of fruit another year. It is impossible that any amount of top-dressing and liquid manure (the pots being exposed) could have produced such crops as have been gathered from these trees and left the trees in such splendid condition as they now are.

The mode of culture described is not an experiment merely: the system has been practised sufficiently long to prove its value. The result is that Mr. Rivers is satisfied that by no other means, not even by having trees planted out and trained on trellises, could the small house referred to have been made to yield so many Peaches; and further, had the house been trellised two trees would have filled it, yielding a feast of fruit, but necessarily a short one, whereas by the present system of having a number of trees and varieties a long succession of fruit is ensured. The perforations in the pots are about an inch in diameter, and the simplicity and success of the plan merit record.

A word on some other features of the nursery. The crop of Peaches and Nectarines generally has been a great one. Upwards of a thousand dozens of fruit have been sold, all grown under glass; some houses having a row of hot-water pipes round them—by far the preferable plan, and some being unheated. Trees of all kinds in pots—there are thousands of them—are being packed for transit; also Vines, of which the demand yet almost exceeds the supply, large as it is. Grown on hot-water pipes, the canes are hard as oak and strong. Trees in the nursery are beautiful in their bright autumnal tints—good proof that the wood is maturing well. Plums Early Rivers and Prince Englebert especially have produced fine crops, the plantation of the latter having yielded three hundred bushels. A new late Plum, Grand Duke, is likely to prove a grand acquisition. It is large in size, rich in quality, and hangs until November. The wood is like that of the Diamond, but the leaves are rather longer; it is an excellent grower and forms handsome pyramids. It is a seedling from Autumn Compôte. The new Pear Dr. Hogg is by far the riches Pear now in season, and there are other seedlings of great promise approaching the ripening stage.

The crop of Grapes on some of the Vines in the permanent house, a low plain structure, is extraordinary, yet the wood is ripening well. Lady Downe's is bearing unusually fine bunches and berries and nearly black. Gros Colman has noble berries, Alicante has a mass of fruit. Madresfield Court and Dr. Hogg very good. Black Hamburgh fine, mostly cut. But the finest in appearance of all the black Grapes is Gros Marce; berries large, bluntly oval, and thickly covered with purplish black bloom. Some of the Muscats have shanked, and many Pears in the open have cracked. But I am now approaching perplexing and debatable subjects on which volumes have been

write more; still, believing that the subjects are not wholly exhausted, I may venture to return to them another day.—J. W.

NOTES ON USEFUL STOVE-FLOWERING PLANTS.

PANCRATIUMS.—Like the Eucharis these are bulbous plants. comprising many species and varieties of great beauty, and are natives of the East and West Indies. They require a They require a rather high temperature, moist and shady position, to grow them well, say a stove heat of 70° in summer and 60° in winter should be the minimum. They can be flowered twice a year, at least a few of the species, such as P. fragrans, P. zevlanicum, and P. rotatum; but if large specimens are to be obtained in as short a time as possible they should only be allowed to flower once a year, and that at their natural period, which is July or August. Young plants should be pushed on by re-peated shifting as soon as they fill their pots with roots. When peated shifting as soon as they fill their pots with roots. When the specimens are as large as required they should only receive a shift every four years. Our largest specimens are in 18-inch pots; in these they were placed five years ago, and last July each threw up eleven scapes, with from eight to ten flowers on each. The soil used is two parts fibry loam, one part charcoal, and one part silver sand and sheep droppings. The loam is broken into pieces about the size of pigeon's eggs, the charcoal the same; when all has been turned two or three times it should then be run through a half-inch riddle, and what remains in the riddle put in the pots. In potting, the soil ahould be rammed very firmly. In the stove they should be close to the glass where there is plenty of light, but shaded from the direct rays of the sun, and they should receive a bountiful supply of water in the summer time, both from the watering-can and syringe. Even during the winter the syringe must be more freely employed than for most stove plants, particularly so if the stove in which they are placed is not furnished with vapour appliances. They are benefited by being turned into a cool conservatory when in flower, and supplied with a little stimulant; it prolongs their flowering season, and also imparts a much finer waxy appearance to the flowers-moreover, they last much longer in a cut state when subjected to this treatment previous.

UBCEOLINA AUREA PENDULA.—This is a plant both useful

and beautiful, but not generally met with. It produces its flowers on scapes, from the top of which they hang in a very graceful manner, so that each can be removed as it opens to be used for bouquets or glasses in rooms, so that each scape pro-duces a supply of newly opened flowers for a considerable time. The colour is also an uncommon one, being a mixture of green and yellow; it contrasts with most colours, and the flowers last well when cut. As plants in pots they are highly decorative for rooms or halls. They are a little shy to cultivate. We have seen them kept in a greenhouse all the year round with considerable success, but we keep ours in the stove in company with the Pancratiums and Eucharises. Diminish the supply of water to a greater extent than for most stove-flowering bulbs; in fact, I have found Aurea to flower better when completely dried off like Amaryllises. The soil used for potting them should be lumpy, say one half fibry turf, and the other half charcoal, sheep droppings or cow manure, and plenty of sand, and potted very firmly in well-drained pots. They like plenty of light, but no direct sunshine. Their time of flowering depends on their treatment. They are flowering here at present, and have been for nearly a month back, a time when other flowers are not plentiful, which makes them more useful and appreciated.—H. ELLIOTT, New Heys.

GRAPES WITHOUT FIRE HEAT.—In a former situation we had a vinery containing the following varieties, which were all started into growth, and the fruit ripened without the aid of fire heat:--Muscat of Alexandria, Mrs. Pince, Golden Champion, and Gros Colman, the bunches being large, and the berries very fine, especially the two latter varieties. berries of Gros Colman were very large, but coloured rather All the others badly, and were rather given to shanking. coloured well, and the berries were everything that could be desired. I do not say they would have coloured and ripened without fire heat in a season like the present, which has been most disastrous for gardeners; but in an ordinary season I firmly believe Grapes can with good management be started into growth, and ripened too, without the aid of fire heat, as I have proved by experience. By keeping the house close, and

written to such little effect that it requires some temerity to only admitting air on very favourable occasions at starting, anyone may grow good Grapes without the aid of fires.

THE ROSE ELECTION.

I AM obliged to think that Mr. Ellwanger has, in his reply to my query as to the garden varieties, purposely omitted Tea Roses. This is the more strange, as it will be in the recollection of your readers that the Tea element in the newer varieties was greatly in excess of the same character in the English list; but, as in the case of the voters here, I did not feel justified in suggesting that there was a misunderstanding. Mr. Ellwanger has prefaced his list by suggestions in a paper entitled "The Best Hardy Roses for General Cultivation and How to Grow Them" as to site, treatment, pruning, &c. In treating of the qualifications for a perfect Rose he remarks that for "general cultivation they should excel in the following particulars and in the order named—First, beauty of colour, as that which first attracts us to the Rose; secondly, form; thirdly, fragrance; fourthly, profusion and continuity of bloom; and lastly, vigour and healthfulness of growth." I am not so certain that all of us would agree to the order of merit here. Mr. Ellwanger then gives the highest possible marks to be attained for these points -viz., 24, 22, 20, 18, 16; total, 100. Every one is perfectly justified in having their own ideas as to the value of certain points, which lead us to form opinions as to relative merits in different specimens, and in differing from Mr. Ellwanger I do not wish to place my ideas against his; but had I to place his five characteristics I should place them thus for garden varieties—Firstly, colour; secondly, profusion and continuity of bloom, and as a sort of rider to these two points I should add variety of bloom. This is a characteristic which it seems to me has been somewhat overlooked in the garden election. Then I am disposed to place his fifth point third, for it is in a garden variety a characteristic of marked importance. Fourthly, form would take my affection; and last to myself would be his third—fragrance. In the paper alluded to Mr. Ellwanger mentions that "a list of this kind would not be complete without mention of some summer Roses. Though blossoming only once a year, some of them, notably the Mosses, are so beautiful as to be essential to a Rose garden of any size or pretension." The list of the thirty varieties is then given, with pretension." pretension." The list of the unity varieties is then given, with the number of the points given for each of the five qualities noted above. Thus, Alfred Colomb heads the list, being marked the highest possible for colour and form—vis., 24 and 22; fragrance, 19; blooming qualities, 15; vigour, 13; or a total of ninety-two marks out of a possible hundred. After the table comes a short notice of each of the Roses, and I am struck by the note to La France—"the sweetest of all Roses; if committed to these are variety this cheed he cur." Here if compelled to choose one variety this should be ours." Here certainly it would appear to be preferred to Gloire de Dijon.

I now place the two lists side by side, premising that Mr.

Ellwanger's list is in order of merit tested by the points allotted to the several characteristics named.

Riection List.

1. La France 2. Gloire de Dijon 3. John Hopper 4. Duke of Edinburgh

Jules Margottin Souvenir de la Malmaison

6. Souvenir de la maimais.
7. Baronne de Rothschild
8. Cheshunt Hybrid
9. Général Jacqueminot
10. Dupuy Jamain

11. Sénateur Valses 12. Alfred Colomb

18. Marquise de Castellane 14. Madame Victor Verdier 15. Marie Baumann

18. Marie Balmann

18. Charles Lefebyre

17. Boule de Neige

18. Ferdinand de Lesseps

19. Prince Camille de Rohan

20. Fisher Holmes

21. Marie Finger

22. Céline Forestier 23. Beauty of Waltham 24. Marie Van Houtte

25. Abel Grand 26. Marechal Niel 27. Anna Alexieff 28. Marie Rady

29, Dr. Andry 30, Souvenir d'un Ami

Mr. Ellwanger's List.

1. Alfred Colomb 2. Mar e Baumann 8. John Hopper 4. Madame Victor Verdier

5. Général Jacqueminot 6. Comtesse C. de Chabrillant 7. François Michelon

7. François Michelon 8. La France 9. Charles Lefebvre 10. Marguerite de St. Amand 11. Louis Van Houtte

12. Jules Margottin (Climbing)
13. Anna de Diesbach
14. Paul Neyron
15. Baron Prevost

16. Marie Rady 17. Madame Boll

17. Madame Boll
18. Caroline de Sansal
19. Baronne de Rothschild
20. Marquise de Castellane
21. Coquette des Blanches, H.N.
22. Coquette des Alps, H.N.
23. Blanchefieur, Provence
24. Eugène Verdier
25. General Washington

26. Prolific Moss 27. Cheshunt Hybrid 28. Cristata, Moss

29. Appolline, B.

These two lists are interesting as comparisons; doubtless the variations of soil and climate have a marked influence on the selections. Some Roses in Mr. Ellwanger's list I have never been able to induce to open respectably, notably General Washington. It is somewhat singular that John Hopper occupies the third place in each list, whilst the Hybrid Perpetuals Duke of Edinburgh and Dupuy-Jamain do not get into the thirty in Mr. Ellwanger's list, although both holding forward positions in the election list; and the same remark applies to the charming autumn bloomer Souvenir de la Malmaison.

Thanking all who have assisted, and trusting the coming winter will deal kindly with our Roses, I conclude the elections

of this year. - JOSEPH HINTON, Warminster.

VERY LATE PLUMS.

When the writer entered business nearly twenty-five years ago the only representatives of late Plums in general cultivation were Coe's Late Red and the Imperatrice. In no branch of hersticulture have more rapid strides been made than with the Plums. Our great fruitist Thomas Rivers, by raising the Early Prolific, started the season for Plums in the end of July (20th to 27th here), and on the 1st of November I gathered fruit of four really fine varieties of late Plums—viz., Wyedale, a dark red of middle size, oval shape, which is one of the most delicious cooking Plums; very hardy growth. Lafayette, a lustious Gage-like Plum of a sweet and pleasant flavour; good grower and bearer. Belle de Septembre, a fine bright red Plum; a strong grower, and likely to bear well when the trees are old. The soid flavour of this is like the Diamond, and though not so rich as the others will be useful in tarts, &c. Pinsily, as Rivers' Prolific opened the season, so that recent acquisition Rivers' Grand Duke fitly closes it. This is a coming Plum; it is of a blue Gage appearance, large, very sweet, and richly flavoured. All these late Plums are suitable for dessert encept Wyedale, and, to use a very forcible expression, do not "tasts of the tree," as many late fruits do, but really partake more of the nature of a sweetmeat.

For my own part I really wonder people take the trouble to raise and bring out good new varieties of fruits, because it is so difficult for growers to induce planters to adopt them. One would almost think that an Orleans, a Green Gage, a Magnum Bonum and an Egg Plum were the only varieties worth growing; and my object in writing these few lines is to induce planters to try these valuable additions to the series of Plums both on walls and in the open—one of our most useful fruits—and all the varieties named are later than Damsons.—GEORGE

BUNYARD, Mardstone.

THE NORTH ASPECTS OF WALLS.

NORTH aspects are generally considered nearly useless so far as fruit trees are concerned. We generally find them very indifferently covered, as if the trees were not worthy of attentiest. This sesson and for several years we have gathered our finest and most abundant crop of Morello Cherries from a north wall. Some of our largest Pears this season are on a similar aspect. Lord Suffield Apple seldom fails to bear a good crop on this aspect. Gooseberries succeed capitally, also Red and White Currants. We have some fruit of the latter hanging now (October 29th) as fresh as in July, and we have no doubt with a little extra attention we could gather good Currants to the middle of November.

Taking these facts into consideration I would certainly advise all who have hitherto neglected their north walls to plant some trees this winter and give it a fair trial. In most cases the sun does not shine much on north walls, consequently the soil at the base of them is always inclined to be damp, and this combined with a naturally wet soil or subsoil is the reverse of favourable for the growth of fruit trees. This can generally, however, easily be rectified by placing a good quantity of drainage under the trees and raising the border well above

the level of the surrounding ground.

If the trees are to be planted against a north aspect it would take much time to renew all the borders, and instead of doing so take out the soil in several places, forming holes 6 feet wide, 6 feet long, and 3 feet deep. In the bottom of these holes place to the depth of 20 inches rough stones, ashes, or anything that will act as drainage. On this a foot depth of soil may be placed; plant the trees above this and cover the roots over with more soil, leaving the mound when planted about 2 feet above the rest of the border. When Gooseberries or Currants are to be planted less preparation will be necessary, but a little labour spent in this way at first is generally the

cheapest plan in the end. Standard Gooseberries, Currants, and Raspberries also succeed in a north border, and when the wall is well covered with Cherries, &c., and the border stocked with such bushes it is both profitable and pleasing.— A KITCHEN CARDENER.

FRENCH NOTES.—No. 4.

PARIS.

I no not know a more pleasant month to be in Paris than September. The days are generally fine, the temperature not too high, the parks and gardens are in their beauty, the trees on the boulevards have not shed their leaves, and the outdoor life, so dear to the Parisians, is in its full swing. There is one drawback-Paris is not there: it is not the season. The upper ten are in villaguatura, either displaying themselves in fancy costumes at Trouville or some other watering place, or else at their châteaux, and so the dashing equipages which make the Champs Elysées and the Bois so gay by day and brilliant at night are wanting. But with this exception there is no month would rather advise those who have not visited Paris to go there than September. True, this year it was not in its usual condition. This year, which has been so disastrous to us in England, has been nearly as much so in France, and in nothing was this more conspicuous than in the appearance of the fruit department in the Halles Centrales. There were Grapes there, it is true, from the south; but the heaps of luscious Figs, the beautiful collection of Pears, and the highly coloured Peaches of Montreuil were but poorly represented, and were also very dear. The Peaches were certainly very inferior in quality to those I have tasted before, and evidenced want of sun both in colour and flavour, while the more common fruits had taken the place of the more refined kinds. There were large quantities of Belle de Septembre Plum and some other coarse-looking kinds. There were at Chevet in the Palais Royal, and Potet and Chabot in the Boulevard des Italiennes, some finer specikinds. mens of fruit, but no way to be compared to such a show as one sees at Solomon's or Garcia's in our own Covent Garden. In truth it is no insular prejudice that leads me to say that nowher in the world, perhaps, are such splendid fruits to be seen as are produced by our vineries, Pine pits, and Peach houses. Greater profusion of course there is, and in some one place greater superiority in one kind, but take it all round we may well challenge the world to beat us. Vegetables were as usual very good. The wet season, too, had not the same effect upon them as on the fruit. There are some which we rarely see amongst us, such as the Aubergine and the Sweet Fennel, the latter very much used by the Italians and said to be very palatable.

The season—which has so damaged the hopes of lovers of the bedding-out system, when leaves have been abundant and flowers scarce, when Alternantheras have perished and Coleuses been dingy-had told with nearly as much effect on the various parks and promenades of Paris; and although the verdure was perhaps more refreshing than ever, yet the briliancy of the flowering plants was considerably dimmed; nor did I notice anything particularly novel amongst the designs of the beds or the plants employed to fill them. A new part has been opened near the terminus of the Sceaux railway—the Parc du Mont Souris. It differs from any of the others that I have seen in Paris in that no flowers are employed in its ornamentation. The effect is made to depend on the skiffel grouping of Conifers. It is on a very elevated spot, and on the highest ground is a Tunisian-looking building, which is in connection with the observatory in Paris. In what may be called the private grounds attached to this there are some flower beds, but all the rest of the park is without them. There are some skilfully executed pieces of rockwork and a large piece of water, and although two railways run through the Parc it is so skilfully managed that it is very little of a dis-figurement. The cold Parisian winter does not allow the choicer Conifers to be used, so that the groups are composed simply of the hardier kinds; but in the course of a few years I do not doubt that this Parc will prove a very attractive addition to the public places of Paris. Right away st exactly the opposite end of the city a new park, or garden, is being formed from the summit of the Trocadero down the slope where the long flight of steps used to be to the Seine. So far as I could judge them (for it was in a very rough state) there was a deficiency of the usual taste displayed in these matters. Large pieces of statuary partly gilt are surely out of place in these days when the superiority of plants has been so universally recognised. The building of the Trocadéro itself is especially ugly, but the view from it of the city is very exquisite. There is also an aquarium in course of formation which promises to be in good taste. Probably on our next visit the whole thing will be complete, and the general effect can be better estimated.

The Parc de Monceaux is, I think, the most finished piece of gardening in Paris. The Parc itself has an aristocratic air about it, while the greatest care is taken in producing by the aid of choice exotics, well-arranged beds, and what is now called carpet or leaf bedding, the happiest effects. One of the most pleasing combinations is a large bed of the variegated Acer Negundo, amongst which some late Phloxes of a lilac shade had been largely planted: these gave a most pleasing effect, reminding one, as one is often reminded by things in nature of some production in art, of those delicate shot silks which at one time used to be so much the fashion. Another very effective bed was one of scarlet Hibiscuses with an edging of white Lantanes. Some specimens of Aloes surrounded by blue Lobelias looked uncommonly well, as did a large bed of Erythrinas, amongst which was a tall-growing plant with long spikes of small white flowers, the name of which I could not find out, but which looked not unlike a Francoa. It was not to be expected that the subtropical plants, such as Ricinuses, Wigandias, &c., should be at all equal to what they usually are, for they delight in a hot warm summer.

The Luxembourg gardens still maintain the character they have always held as something distinct. There is more permanent gardening here than in any of the other gardens. Roses, Althæas, bushes of Honeysuckle, Pæonies, &c., occupy permanently the centre of the beds, and then the spaces are filled in with herbaceous and bedding plants. This gives greater variety, but I very much question whether for a public garden it is so effective as that pursued in other parks; but there is much more of stiffness in the whole of the surroundings of the Luxembourg which makes this style of gardening more suitable. The season was not without its effects here also, and that completeness of effect which is generally so characteristic

of the gardening in Paris was absent. The Boulevards were as usual very effective—unique in their peculiar style of beauty; but in walking along them I was struck with the different aspect of various portions according to the trees used. These are the Ailantus, Plane, and Horse Chestnut. All along the Boulevard des Capucines, Boulevard des Italiennes, Boulevard Poissonière, where the two former had been used, there was the appearance of summer with their fresh verdure and grateful shade; but along the Boulevard de St. Martin up to the Place Château d'Eau, where the Horse Chestant was used, the leaves had fallen and gave quite a wintry appearance. It is almost a pity that the same trees were not used the whole length. Of course in early spring the Horse Chestnut would have the advantage; but, after all, the Plane is the tree for planting in towns, and it must be a matter of congratulation that it has been so used on our Thames Embankment, which, notwithstanding its many drawbacks, bids fair to be the finest riverside drive in Europe.

And so end my French notes for 1879, made during a very brief visit, but full of quiet enjoyment and pleasure.—D., Deal.

EVERGREEN CLIMBERS—COTONEASTER SIMMONDSII.

SIDNEY SMITH once laughingly said of an acquaintance that he had been heard to "speak disrespectfully of the equator." Now, I think "GLOUCESTERSHIRE PARSON" (page 342) speaks disrespectfully of the Cotoneaster. C. microphylla is all he says of it; but does he not know C. Simmondsii? The leaf is a beautiful shade of green, very glossy, and the scarlet berries are very numerous; they are large oblong berries of a brilliant scarlet colour, and all last winter made "a sunshine in a shady place," till they were picked off by the starving birds. This plant is trained round and over a Wyatt window, facing almost dne north. It is kept closely spurred in, and is one of the best evergreen climbers of its kind. It is not a graceful plant. It is stiff and conventional, or, as a friend one day scoffingly remarked, "very high art;" but it is invaluable for covering a wall with a north aspect, as it is very hardy and grows quickly.—Busy.

the York Gala, the colour being perfect but the hunches not over large, and to my surprise the judges put me in the second place, Madresfield Court in front. Was this right? I would say to all pot Vine growers if they have not tried Gros Colspan say and the first in an easily. These are Grapes "to see once and dream of for ever."—B. GLINERT.

BOUVARDIAS.

Now that we are passing through the dullest portion of the year we look principally to our greenhouses to furnish us with floral beauty, and it is to our own interest to observe those plants which are the easiest to obtain, and which at the same time give us a fair result for the trouble bestowed upon then Bouvardias stand in the first rank of merit as decorative plants at this season of the year, and there is no reason why we should not have them in flower from this time until the end of March. provided we have a good succession of plants to depend upon. In the Bouvardia we have elegance of flower—form, rich and valuable colours, frequently with delicious perfume. Has bouquet work of every description they are well adapted; in fact, where flowers are in great demand for cutting purposes they are invaluable.

Propagation.—Start the stock plants early in the new year, so as to secure as early a batch of cuttings as possible. They will strike in a good bottom heat in a few days, the potential employed being well drained; in fact, half filled with potshauls, and the soil should be composed of equal parts of good mature fibrous loam, finely sieved, well-decayed leaf soil, and above sand. After the cuttings are well rooted pot them off in small. 60-size pots, and encourage growth by keeping them in, a close house with a temperature of 65° on 70°, with plenty of moisture both in the atmosphere and at the root. Step them at every joint they make, which will give them a frag-branched and dwarf appearance. There can be no greaten mistake made in the cultivation of these plants than to allow them in a young state to make long shoots; but they should be well stopped until they have made eight or ten or even twelve young shoots, by which time the small pots will be well filled with roots, when larger pots will be required.

The size of pot depends entirely on the requirements. For general purposes 48-pots are the most serviceable. Employ in the second potting a soil composed of good mature loam, leaf soil, well-decayed cow manure, with some gritty sand, well draining the pots, and potting the plants moderately firm. Place them again in a close house with plenty of moisture and a cool bottom for the pots to stand upon, as a dry bottom is not so good. By the middle of June they may be removed to a cold pit, keeping them close and well shaded from direct sunshing. at first, and always more or less shaded, never allowing them to want water, but give them it in abundance throughout the season, and stop them until the end of August, as the flower clusters have then a good time to form, allowing them a good supply of air at all times. When the pots are well filled with roots water them every week with good liquid manure, which improves them greatly. They may remain in ordinary seasons in a cold frame until the middle or end of September, when they will be removed into the house, but do not greatly increase the temperature unless they are required to flower early. To give them a neat appearance they require staking. After the first flowering they may be cut well back and pushed on in heat, and they will readily and soon produce a second batch of flowers.

The following are the best and most useful species and varieties for all purposes :- Vreelandii, one of the best whites, very floriferous, good clusters of flowers, and most valuable for botton-holes, &c. Elegans, the counterpart of the last; good grower, free flowering, flower clusters fair size, well set with rich scarlet flowers of great substance. Hogarth, a beautiful hybrid, similar in habit to Vreelandii, producing good cymes of bright scarlet flowers; a very neat and good variety. Jasminiflora, very free, producing lax cymes of pure white longtubed flowers, deliciously scented; one of the best, but very liable to insect pests: look after them. Maiden's Blush, similar in growth and flowering to the first, but a lovely blush colour, which renders it distinct and charming. Leiantha, a good very small-growing variety extensively grown for market purposes, producing bright red flowers. Delicata, flowers very Por Vines—Prabson's Golden Queen.—I am quite with light rose, freely produced. Van Houttei, a very fine scarlet-Mr. Iggulden on the desirability of growing this as a pot Grape. In 1878 I fruited six canes, and exhibited three bunches at this is perhaps the finest of all Bouvardias, producing large corymbs of pure white large flowers, very strongly and sweetly scented. Some regard this as a shy bloomer, but when well handled it is free enough, and every flower produced rewards the cultivator. Longiflora is also a splendid variety, producing, long-tubed white flowers of great substance. Candidissima is of all perhaps the easiest (if we may use the term) to manage. It grows very freely and flowers as freely, and the latter are very rich and desirable. There are a few others well worth growing.—T.

FLOWER GARDENING MADE EASY AND BEDDING MADE PRODUCTIVE.

BAD seasons, bad harvests, and but little rent make a gardener's situation on large landed estates anything but pleasant; still I fully believe there are some beneficial results. It tends to awaken us to use economy; and if there is any scheming or generalship among gardeners these are the times to bring it out. I have here under my charge a very large flower garden, and one particular site in it is a long border skirting the lake. which required from five to six thousand Geraniums to fill it. This season I was instructed not to bed this site out at all unless I could make it both ornamental and at the same time profitable. Not liking the idea of a bare border all the summer I ordered 3 ibs. of Beet seed, known as the Pine Apple, drilling it in rows at 1 foot apart. The seedlings came up well, were duly thinned and kept clean. A yellow Viola was planted round the edges of the bed. Just now when all other beds are bare this border is simply beautiful, and will last until affected by frost. I calculate the Beet will be worth 1s. per dozen, and at that price I shall realise, if only one-half is marketable, the respectable sum of £6 sterling. In conclusion I may say practice makes perfect. If I had dotted in a few clumps along the centres of the beds of Ribbon Grass it would have been a great improvement; however, next season I will, if spared, introduce the grass above mentioned.—KITCHENER.

WATER PLANTS.

Few things are uglier than a muddy horsepool by the roadside, especially when it is fringed with slime in which the loose feathers of the ducks which make the pond their playground are sprinkled about so as to make even the dirt fook dirtier. There are many such ponds in my parish, but one has a glory all its own in a stately plant of the great Water Plantain (Alisma Plantago). This plant happens to grow just in the centre of the pond, and the strong upward growth of its beautiful leaves contrasted with the light feathery sprays of the flower, and the broad shadow of the whole reflected in the water, are so extremely beautiful that they redeem even the muddy horsepond from ugliness. Most of the endogenous plants have something stately in their appearance, and they seem to have a peculiar liking for water. The Alisma is not the only wild flower which adds grace and even dignity to our roadside pools. In many places the Bullrush is abundant, and other tall Sedges and Grasses, combined with the broader leaves of the wild Iris, make a beautiful border to some shadowy piece of water lying low under the shade of a dark wood.

Another beautiful wild endogen is the Flowering Rush (Butomus umbellatus), which is comparatively rare, but may be found occasionally growing in stagnant water. It grows in this country, but is not easily found. All these wild plants are suitable for the garden if there happens to be a pond large enough for their stately growth. They are fortunate who possess such a pond or natural water in any form in their gardens, for in out-of-door work nothing is more interesting than the cultivation of aquatics and damp-loving plants. The cultivation of Richardia æthiopica (née Arum) seems to increase year by year as the beauty of its leaves and flowers becomes more and more appreciated; but we usually see it in large pots, where no doubt it attains a greater size than under any other treatment. But in Cornwall it is frequently planted in large ponds, and in such cases it flourishes fairly well, dying down every winter and reappearing with the spring. It looks particularly well growing actually in water, and I have been pleased with the effect of it in my own garden, simply plunged pot and all in an artificial pool. Under these circumstances a network of roots quickly forms on the surface of the pot, and the plant will thrive well during the summer months.

I must confess to a failure with Aponogeton distachyon. It

grows abundantly in the pond of a garden belonging to a friend in South Devon, and the flowers there are most useful for gathering in winter, as they are curious and sweet-scented. I have had plants from that pond given to me, but without success. The pond in which it thrives so well has a gentle stream passing through it, and I attribute the great luxuriance of the Aponogeton to the fact of the water being at once still and yet changed. I have seen this aquatic grown at Kew in a bellglass turned upside down. It was very different from the same plant in South Devon, but yet it was an interesting plant, and I think I shall make another attempt to grow it in that fashion. It seems to me to have a great objection to artificial heat, as I have tried it my vinery, where it soon disappeared, and I have known it share the same fate under similar circumstances in another garden. It is one of those provoking plants which when once they take to a place grow like weeds, but the difficulty is to get them to take.

The Water Lilies are perhaps the most beautiful of all aquatics, and yet they are so troublesome in their cuckoo-like determination to oust other things from their nest and to get possession of the whole for themselves, that it is necessary to be careful in introducing them, unless the ornamental water is sufficiently extensive to give them plenty of room. On the banks of such a piece of water, be it large or small, the first things to plant would be Arundo conspicua and the Pampas. I have seen lately the assertion that the former is as hardy as the latter. I hope it may be so, but my own experience is, that in the bitter cold of last winter the Pampas survived, though somewhat injured; the Arundo died. However, my plant of the latter was small, the Pampas was well established; this last has now quite recovered from the severe winter, and is throwing up as many heads as usual, though more than a month behind the usual time.

I believe nothing could be more beautiful on the banks of artificial water than great cushions of moss and such wild flowers as like a moist dripping atmosphere, if they could only be made to grow as they do in the far west. Anyone who has seen that perfect gem, the Ivy-leaved Campanula (Campanula hederacea) growing in its native haunts with the lovely Bog Pimpernel (Anagallis tenella) cushioned also by its side, would agree with me that scarcely anything more beautiful can be seen in our gardens. The light green of the Cornish Moneywort (Sibthorpia europeea) is often found in great abundance close at hand, and adds another beauty to the soft lovelines of those rich dewy banks of moss, Ferns, and flowers which are to be found in the deep wooded valleys of Cornwall and Devon. I am afraid it is scarcely possible to reproduce them artificially, and perhaps some would say it would not be right to attempt it. But comparatively few penetrate the recesses of a Cornish wood except on the day of a grand battue, and therefore the exquisite beauties of Nature to be found there are almost unseen. It would at least extend the area of such delights if we could reproduce them in our garden, although we who know them at home might not perhaps care much to meet with them when they would inevitably bear some signs of not being quite happy.

happy.

I was crossing the Southampton Water by the steamboat to Hythe last week, and we met men loaded with Ferns. "Ah," said my friend, who lives in the Forest, "we shall soon lose all our Ferns in that way." If the Swiss have found it necessary to pass a law to protect the Edelweiss, we may have to protect our plants at home, as we do already protect our birds, sooner than some of us imagine. As yet, however, though the Cornish cliffs have been denuded of the beautiful Asplenium marinum, and though I see the Sibthorpia offered for sale, I have little fear for the destruction of the Anagallis.—A GLOUCESTERSHIEE PARSON.

ROSES-PROTECTION.

MR. BARDNEY gave good advice on this subject. I last spring planted ten weak plants of Céline Forestier, and muffled them up as advised by Mr. Bardney. They have done capitally, both as regards growth and efflorescence. In passing I may observe that Gloire de Dijon, Céline Forestier, and Triomphe de Rennes are three of the most gratifying Roses. They are here good on all stocks, in all situations, and throughout the season. It is impossible to praise them too much. I have muffled up this day (November 5th) four hundred Roses, and have 2100 more to protect. I believe that from the saturated state of the soil if frosts are severe sad will be the effects on vegetation. The late Mr. Rivers told me years ago

that 5° of frost would kill Roses. Muffling up is not only a great protection, but it causes drainage. I advise persons with wet ground to put down deeply an iron bar on three sides of the plant to cause artificial drainage. The Manetti stock is an admirable stock for dry ground, but it does not like lying in continual wet without adequate evaporation. Roses bought by the hundred and paid for with ready money are so cheap

that it is not worth trying to recover cripples.

I quite agree here with Mr. Baker—"Hercules." Formerly Mr. Hedge was Hercules, and I greatly regret his retiring from exhibitions. During the several years that I helped to adjudicate the Roses at Kensington none ever gave me greater pleasure than Mr. Hedge's Roses. They were not divisible into good, bad, and indifferent, the usual character of exhibition Roses, but were universally masterpieces. The rules laid down for adjudicating Roses are good, but too cumbersome for large exhibitions. They would require double the number of censors or more.—W. F. RADCLYFFE.

NOTES ON THE LATE FRUIT SHOW AT HEREFORD.

IT is a pardonable subject of congratulation in the case of so small a county as Hereford that as they held during the summer beyond all comparison the finest exhibition of Roses both in point of size and quality, so there was collected in their ancient city last week, in the words of your admirable and complete report, "by far the greatest exhibition of Apples and Pears of the year."

Never, surely, were a Committee in this age of surprises so agreeably surprised at the result of their labours. Gloucestershire had given up their ancient fruit exhibition as this year hopeless. Many there were to counsel us to go and do likewise. Some, in grim irony, allowed the cracks in the fruit would be most useful to stick labels in.

The Exhibition has, however, taken place, and successfully; and, thanks to the presence of our chief Esculapius at the helm and our prince of pomologists at the prow, proved not only beneficial to those immediately concerned in the undertaking, but, I would believe, to fruit culture generally.

Among the many questions that were discussed by Apple and Pear growers present, the two following are of interest:— Whether dessert Pears, such as Beurré Diel and General Todtleben, should be entered also as stewing or culinary varieties; also, as to whether Apples so closely synonymous with each other as King of the Pippins, Stoke Pippin, Seek no Further, and Golden Winter Pearmain should be classed as separate varieties, or merely synonyms of Golden Winter Pearmain. While I quite agree with Mr. Killick—to whom we are under, let me add, the most pleasing obligations for his valuable contributions and hearty help—that Warner's King was the Apple of the Show, I hardly think he would give the pride of place to this variety where other Apples are exhibited in a like degree of excellence. I should like him to have seen the Blenheim Pippin as it was shown last year at Gloucester, and where it carried off every first prize, and deservedly so. This year this grand variety shows small and bad everywhere.

I should also like to endorse the opinion of your reporter, which I also see shared by Mr. Killick in his notes on our

Show, that with the exception of the Holme Lacy fruit planta-tion and a few others, quite as the exception not the rule, the skilled attention so apparent in Kent is lacking with us, and gives the right clue to our Herefordshire orchards not taking up the front rank, to which their rich warm soil undoubtedly entitles them. Everybody knows the climate of Herefordshire is humid, and especially is this failing noticeable in a wet sunless season like the present, when it has been especially trying to vegetation and maturation. But still, as Mr. Killick points out, with such fine undulations to select from (and in America I am told such situations are considered by their owners as absolutely necessary if they would avoid the fill effects of early frosts, mildew, &c.), I feel sure that in flavour, colour, and size the orchards of Herefordshire ought to rival if not surpass those of Kent or any other county in England. Such was the verdict of old pomologists of the end of the seventeenth century; but alas! the situation and cultivation of most of the orchards of our boasted highly civilised nineteenth century is of so scandalous and neglected a character, that one would never be surprised to see the ghost of the classic Evelyn rising up and mournfully accusing so great a waste of Nature's wealth and their own opportunities. Allow me to take this

shire Pomona, to thank our kind friends both at home and abroad, who so unselfishly came to our help, for the pecuniary inducement was almost nil, and made us almost forget, in their own geniality and in the rich abundance of their contributions, the dreary unproductiveness of the season.—The Hereford-SHIRE INCUMBENT.

SHEFFIELD GARDENS AND GARDENERS.—No. 5.

EXAMPLES of shrub, fruit, and general plant culture having been noticed, Orchids as grown in the district merit attention.

The finest collection of these plants to be seen in or near Sheffield is at

WESTBROOK.

Westbrook is the residence of Henry Wilson, Esq., who is a great manufacturer of snuff and a great patron of Orchids. The snuff mill is near to the residence, the small garden attached to which contains several good houses filled with an extensive assortment of admirably grown plants. The whole place is redolent of snuff; and whether it is to this fact that the extreme cleanliness of the plants and their freedom from insects is attributable I know not, but this I know that it would be difficult to find Orchids in better condition than Mr. Wilson's are, as grown by his experienced gardener and skilled cultivator Mr. Clements.

Many of the plants that once formed the celebrated Meadow Bank collection are here, and others have been obtained from various sources until the stock has become of great value, having, indeed, recently been appraised at between £3000 and £4000. In the East Indian house are many fine Vandas, Aërides, &c. V. tricolor formosa is a splendid specimen. remarkable for its rich dark green foliage; and equally striking is the Chatsworth variety of V. suavis, and a notable plant of V. Westbrooki; Aërides virens Dayanum is very fine, and Angræcum sesquipedale is a fine broad-leaved specimen; Phalænopses—amabilis, grandiflora, Schilleriana, and Lüddemanniana—are numerous, and, though not large, are in superb condition. Suspended from the roof are examples of Dendrobium Wardianum in choice variety. Amongst them is the plant, with very small growths, that won the Bateman prize some years ago; it is a superior variety, but not equal to one purchased from Messrs. Veitch, which Mr. Clements considers beautiful form of this fine Dendrobe he has ever seen. The growths are rather slender, but the flowers are described as really grand. Some other examples of this species are maturing twelve long growths. D. Falconeri is good, but a finer plant in a cooler house has produced two hundred flowers. Very good are D. crassinode and D. Bensonies, of which there are about fifty plants, and D. McArthuri is very strong. On the side stage are remarkably fine specimens in pots of D. Schroederi, D. densiflorum, and some others, 2 to 3 feet in diameter; and Lælia autumnalis has made eighteen growths. The house is rendered further attractive by some well-grown Nepenthes (Hookeriana, elongata, and Rafflesiana), with a profusion of fine pitchers.

The Cattleys house contains a great number of valuable specimens, remarkable for their thick leathery leaves and deep green colour. Of C. Mendeli there are five to six dozen excellent plants, and about the same number of C. Trians. C. Warneri is represented by several plants of extraordinary substance, and C. gigas is equally fine. In this structure are many plants of Odontoglossum vexillarium which have made five or six growths, and numbers of O. Phalsenopsis, O. Roeslii, and O. Pescatorei in superior condition. Mr. Clements is averse to high night temperatures. This house at night ranges from 58° to 60°, and it is scarcely possible to imagine plants in more thoroughly satisfactory state.

The Odontoglossum house contains numerous and healthy examples of the several species. There are hundreds of plants of such as O. Alexandræ and O. cirrhosum of various sizes, with superior specimens of O. Andersonianum, O. citrosmum, O. grande, and others: Masdevallias are also extremely healthy. The system of culture adopted is to maintain a regular temperature, somewhat cooler in summer and warmer in winter than is generally adopted, and it is evident the plants enjoy their treatment. A mixed house, as its name implies, contains a varied assortment of plants, some of which were flowering, including several examples of the charming Cattleya marginata, Oncidium Rogersi, O. cruentum, and Odontoglots in variety. Noticeable was a very healthy plant of Lycaste Skinneri alba, opportunity, as Chairman of the Committee of the Hereford- | with four fine growths; indeed, many Orchids were noticeable

that cannot be particularly referred to, but sufficient has been said to show that Mr. Wilson's collection is a very fine one. The plants are also in unsurpassable condition, as all will admit who visit the "snuff mills" at Westbrook. They will learn, too, even if they are prejudiced against it, that certain benefits attach to the peculiar stimulant, for Mr. Wilson has built some half dozen churches and schools, and is in many ways a benefactor to the district. A large span-roofed vinery affords agreeable shade to many Orchids, and the Vine—for there is only one-produces two hundred bunches of Grapes annually, averaging 21 hs. each. This house was further accommodating a number of excellent Azaleas. There is also a small conservatory and stove particularly clean and enjoy-able. The pleasure of a visit to this garden is greatly enhanced by the courtesy and genial converse of its excellent manager, Mr. Clements.

CHRYSANTHEMUM SHOWS. LAMBETH AND PUTNEY.

LAMBETH.-First on the list of Chrysanthemum Shows was that LAMBERTH.—First on the list of Ohrysanthemum Shows was that half on the 10th, 11th, and 12th iast, by the young urban Society located in the berough of Lambeth; and taking into consideration the lateness of the season, the early date fixed, and the difficulties attendant on the production of flowers "within a radius of a mile of the Hiephant and Castle," the Society may be deservedly complimented upon the excellence of their exhibition. As usual the Show was held in the Borough Road Lecture Hall, and the general arrangements, which devolved upon the Honorary Secretary, Mr. W. T. Summers, were appropriate and tasteful. The stands of arrangements, which devolved upon the Honorary Secretary, Mr. W. T. Summers, were appropriate and tasteful. The stands of blooms were principally arranged upon tables down the centre of the Hall, and the standards were placed in lines near the walls, the centre of the tables and other spaces being occupied by miscellaneous plants centributed by the members. At the upper part of the Hall was a large group of foliage plants from Mesaus. John Laing & Co., Forest Hill, which formed a most agreeable background. The number of exhibits was below that of previous years but that might be expected, and it is only surprising that years, but that might be expected, and it is only surprising that so many flowers could be cut thus early. The standard plants were neatly trained, but the flowers were small, although in most cases well formed. Mr. Wilsher secured the chief prize in several of the classes devoted to these plants with specimens of medium size, and he was closely followed by Mr. Addison. The cut blooms were generally good, and in one or two instances excellent. In the classes for twelve or six incurved varieties Mr. A. Ball held the premier position, his collection including good representative flowers of Beverley, Golden Beverley, Nil Desperandum, Prince of Wales, and George Glenny. Mr. Crisp's first-prize stand of six of Wales, and George Glenny. Mr. Crisp's first-prize stand of six blooms of the variety Mr. Bunn was very even and good. In the two principal reflexed bloom classes Mr. Wilsher was first with flowers of medium quality. The Anemone varieties were rather poor, but the Japanese varieties were well represented. Among the latter Mr. Tracy's six blooms of James Balter were especially noteworthy for their size and form, and well merited the premier prize in the class. The same exhibitor obtained the prize offered for the best twelve Japanese blooms with a good collection, including fine flowers of James Balter, Fair Maid of Guernsey, and Bismarck. Mr. Clarke's collection of six also included fine examples of The Cossack, Elaine, and Garnet. The prize for the premier bloom in the Show was awarded to Mr. Wilsher for an exquisitely formed flower of George Glenny.

PUTNEY.—Last year this Society held its first Show, at which blooms were staged equal to any at other metropolitan exhibitions. This year the blooms as a rule were considerably smaller, the date of the Show being fully a week too early. Some of the flowers had evidently been forced, which necessarily affected both their substance and colour; and several plants, especially the Pompons, presented a drawn appearance. Yet notwithstanding the drawbacks of the season some excellently grown plants were exhibited, and several flowers of great merit were staged, and the large assembly room, which was quite filled, presented a very gay appearance.

gay appearance.
in the nurserymen's group of twenty-five plants, distinct, Mr. in the nurserymen's group of twenty-five plants, distinct, Mr. Moore of the Richmond Nursery, Putney, won the first position with dwarf fresh specimens, very fine in foliage, and containing several good blooms; Mr. Stevens, St. John's Nursery, Putney, closely following with a well-bloomed collection, but the plants rather drawn. In the gardeners' corresponding class Mr. Whittaker, gardener to T. Williams, Beq., was easily first with admissibly grown plants, fine in foliage and blooms; Mr. Ansell, gardener to J. Reid, Beq., being a very good second. In the classes for six and four specimens respectively Mr. Handley, gardener to Miss Pearson, Victoria Road, Wimbledon, won beth the first prizes with maquestionably the best plants in the Show. The plants had been stopped once, and were then trained in a natural upright position, each bearing blooms of exhibition quality. Mr. Whittaker and Mr. Pithers, gardener to C. F. Williams, Eq., Munster House, had prizes in these classes with dwarf-trained plants. Mr. Whittaker

was also the premier winner in the classes for six Pompers, a specimen Pompon (White Code Mulli), and a large-flowered specimen (Triomphe de Most). Mesura. Ansell, Handley, and Pitters taking other prizes in those classes.

men (Triompha de Mosd). Mesars. Anseil, Handley, and Pithen taking other prizes in those classes.

Cut Blooms.—Mr. Handing, gardener to T. D. Galpin, Esq. Bristol House, Putney Heath, was an excellent first in the class for twenty-four incurved varieties, very good amongst which were Alfred Salter, Queen of England, Pink Venus, John Salter, Prince of Wales, White Venus, Empress of India, Beethoven, Novelty, and George Glenny; Mr. Handley being a good second with smaller but compact and well-formed examples. The same exhibites obtained the same positions in the class for twelve blooms, bein staging excellent stands, especially the former. For six blooms Mr. Bentley, gardener to Sir Thomas Gabriel, Bart., Edgeounder Hall, Wimbledon, secured the first position with nearly perfect flowers of Empress of India, Queen of England, White Globe, Prince Alfred, Novelty, and Alfred Salter. Mr. Harding was a good second, and Mr. Kendal third. The last-named exhibitor had no opposition in the Anemone-flowered class, and was awarded the first prize. Mr. Harding, who is evidently a skilled grower, staged by far the best blooms in the Japanese classes, but by a slight and innocent mistake in staging he could not be awarded the first prize, but was strongly recommended for an extra prize-

staged by far the best blooms in the Japanese classes, out by a slight and innecent mistake in staging he could not be awarded the first prize, but was strongly recommended for an extra prize—of equal value if possible—Mr. Bentley being placed in the first position. Mr. Harding was placed first in the class for six. The best blooms in these classes were Elsiac, Red Dragon, Gloire de Toulouse, Nuit d'Hiver, Fukton, Fulgore (very pale), Peter the Great, Blanche of Castille, James Balter, Plantagenet, and Criterion. Prizes were also offered for atove and greenhouse plants and Ferns, in the former class the chief honours going to Mesen. Kendall and Stevens, and in the latter to Handley and Kendall, all staging creditable collections. Table plants were well shown, Mr. Pithers being an excellent first with bright fresh examples of Crotons Queen Victoria and Weismannii, Cooos Weddellima, Dracena Cooperi, Areca crenata and an Acalypha. Mr. Whiteher was a very good second. This exhibitor also staged the hest Zonal Palargoniums, White and Salmon Vesuvins being especially attractive. Groups of plants arranged for effect (the prizes given by Mr. Stevens) were excellent. The two collections of Mesen. Kendall and Pithers were extremely close in point of merit, but the flowers in the former, principally Roman Hyscinths, turned the scale in Mr. Kendall's favour. Extra prizes were deservedly given to Mr. Kendall for remarkably fresh and dwarf Cockscomb, Mr. Stevens for a beautifully arranged wreath, and Mr. Pithers were bright Celosies. Bongmate were conserved and lumov.

scale in Mr. Kendall's favour. Extra prizes were deservedly given to Mr. Kendall for remarkably fresh and dwarf Cockscombs, Mr. Stevens for a beautifully arranged wreath, and Mr. Pithes he bright Celosias. Bonquets were generally too exowded and lumpy. The best hand bouquet was exhibited by Mr. Ward, gardener to D. Morgan, Req., Boehampton House; and the best arrangement of Chrysanthemums and Masidenhair Ferns by Miss Chard.

Fruit was generally good, Apples especially. Messrs. Ansell and Milner were the prisewinners in the Grape classes, the fumer being first for black, and the latter for white Grapes. Mr. Milner was also first for dessert Apples with Ribston Pippin, Cor's Orange Pippin, and Scarlet Nonpareil; and Mr. Kendall for culnary Apples with Cellini, Cat's-head, and Nelson's Giery, Warner's King, Alfriston, and Blenheim Pippin were will shown. Mr. Fanning, gardener to Madame Digby, had the principal prize for eight dishes, distinct, given by F. Vekes, Req., was won by his gardener (Mr. Jeffrey), but only by one point, His collection included Veitch's Autumn Giant Cauliflower, of unsurpassable quality; excellent Savoys, Potatoes, Celery, Tomstoes, Mushrooms, Cncumbers, and a dish of Seakale. Mr. Kendell was second; his Mushrooms, Brussels Sprouts, Tomatoes, and Beet being very superior. In the class for six dishes the prise went to Messrs. Jeffrey, Fanning, and Whittaker respectively, all staging superior produce.

Such is an outline of this very creditable Show of this young Society—a Society which includes a number of good gardenes,

all staging superior produce.
Such is an outline of this very creditable Show of this young
Society—a Society which includes a number of good gardensus,
has a most competent Secretary in Mr. Moore, as able and industrious Committee under the efficient presidency of Mr. Pits,
and a veluable supporter in Mr. Stevens, and only needs the
generous support of the district, which it deserves, and it should
them produce one of the best autumn shows in the suburbe of
London. London.

NOTES AND GLEANINGS.

AT the meeting of the Fruit and Floral Committees of the BOYAL HORYBOULTURAL SOCIETY to be held on Tuesday next, 18th inst., Mr. R. Gilbert, Burghley, proposes to exhibit a group of his fine double Primulas, also a collection of Grapes. Mr. P. McKinley, Penge, will exhibit a large collection of Petatoes. From the Society's Gardens, Chiswick, will be sent a collection of Abutilons in flower. The competition for Manufacture of Abutilons in flower. Messrs. Suttons' prizes promises to be very spirited. An is-tenesting meeting may, therefore, be confidently expected.

- THE CHRYSANTHEMUM SHOWS have now communesced and some of the societies offer liberal prizes, including saveral valuable caps, &c. At the Walton Show, which is held to-day (Thursday), a silver watch will constitute the principal prize. On November 19th-20th the Borough of Hackney Society will hold their Exhibition at the Royal Aquarium, and among the prizes will be eight silver cups, five valued at £5 each and three at £4 each. At the Kingston Society's Exhibition on November 20th-21st a champion challenge vase valued at twenty-five guineas, and £3 in cash, are offered for the best collection of forty-eight blooms consisting of equal numbers of Japanese and incurved varieties. The Croydon Society will hold their Show on November 21st-22nd, and a silver watch is offered as a special prize by Mr. C. S. Bowman, Croydon, for twelve cut blooms of incurved varieties. At both the South London and Camberwell Societies' Exhibitions, November 24th-25th, a silver cup will be awarded for the best six plants, and a silver watch for twenty-four cut blooms. A silver cup will also be competed for at Sheffield on the 24th; and good prizes are offered at Liverpool on the 18th, and Birmingham on the 26th inst.

—— THE Hon. Secretary (Mr. A. Chancellor) of the BICH-MOND HORTICULTURAL SOCIETY informs us that the numerous applications for schedules and notifications of intending exhibitors from all parts of the country suggest that the Society's first autumn Show of CHRYSANTHEMUMS, fruit, &c., to be held at the assembly rooms of the Castle Hotel, Richmond, on the 18th and 19th inst., will be an extensive one.

A LABGE number of OBCHIDS are now flowering in Mr. B. S. Williams' Nurseries, Upper Holloway. About thirty species and varieties are in flower, and many of them can rarely be seen in more excellent condition. Cypripediums are well represented; the most noticeable being C. insigne Maulei, C. venustum spectabile, C. Schlimii alba, and C. Roezlii; while fine specimens of C. insigne will shortly be grand. The diminative but pretty Pleiones are in good form, P. Wallichii, P. maculata, and P. lagenaria being the most attractive species. The bright little epiphyte Sopronitis cernua is also flowering freely en a block. Oncidium ornithorhynchum album forms an agreeable contrast with the purplish flowers of the species. Burlingtonia decora picta is bearing numerous peculiar and pretty flowers, the white labellum and purple-spotted sepals and petals rendering it very distinct. Calanthes, Oncidiums, Odontogłossuma, and Vandas are all in excellent condition, the fine Dalkeith variety of Vanda tricolor being especially notoworthy. The Restrepias are represented by R. autennifers and R. maculata, both pretty, the former being somewhat darker in colour than the latter. Many other fine Orchids are in flower, which we have not space to notice at present.

ONE of several very distinct and noble-looking species is LYCHNIS FULGENS, giving a display of colour in season hardly to be expected when planted in a mass in a warmborder. Seeds sown early last spring produced several young plants strong enough to flower this autumn; and there is a great variation in the colours, passing from bright searlet to dull crimson. The furcate fleshy rootstocks prefer a rather dry position during the winter. L. Senno is also an attractive species. It grows a foot or more high, erect, each stem bearing terminal flowers often 3 inches across, of a bright searlet colour and very durable, and the plant is perfectly hardy in the south of England.

THE three following are among the best of all the FRITILLARIAS known to cultivators, and all are of recent introduction, at least to commerce. F. recurva is a handsome little species, varying greatly in height, from 6 to 12 inches, each stem bearing a solitary flower, which is bright scarlet marked with yellow and exceedingly showy. F. pudica is also a very showy species, growing from 6 to 9 inches high, the stems supporting from two to six pendulous flowers of a bright golden yellow colour. F. atropurpurea.—This species, a native of Oregon, produces dark brownish-purple flowers chequered with yellow on very slender stems about 1 foot or more high. All the Fritillarias are handsome, and the lover of hardy bulbs should secure a collection.

THE pretty little VERONICA REPENS has been known in our gardens for a considerable time as one of the best plants for covering spaces on rockeries, &c. Lately, however, and notably in the season just past, it has been tried for carpet bedding as a groundwork, for which it is well adapted. It grows rapidly, requires no clipping except the edges. It is propagated very easily, and is perfectly hardy.

- AMONGST scarlet-flowering hardy border flowers the

semi-double GEUM COCCINEUM (figured on page 127, vol. xxxv.), stands high; it is to be much esteemed, not only for its large bright scarlet flowers, but also on account of the long period it continues flowering. Commencing in early summer it only discontinues flowering when severe frosts destroy the stems. It is most suitable for bonquets. One thing in favour of its greatly extended cultivation is the fact of its coming true from seed.

WHERE a first-rate WHITE DAHLIA is required, a correspondent highly recommends Guiding Star; it is one of the bouquet varieties, pure white, and of excellent form; while the flowers are produced in abundance.

—— AT Newton Hall, Stockfield-on-Tyne, there is in bloom this season a DRACÆNA INDIVISA of the following dimensions:

— Height of plant, 14 feet; spread of leaves, 6 feet 4 inches; length of flower spike, 4 feet 8½ inches; diameter of flower spike, 2 feet 8 inches.

AMONGST recently introduced hardy plants very noticeable is CALANDRINIA NITIDA. The leaves are about 4 inches long, oblong ovate, smooth and fleshy, thus differing materially from the other perennial species in cultivation—vis., C. umbellats. The flower stems are from 6 to 9 inches high, bearing several flowers at the top, which have green fleshy calyces spotted with black, and the petals are bright magenta, the flower being about 1 inch in diameter. In a bud state the flowers are pendulous, but erect when expanded. The plants we have were raised from seed this year, and have made large fleshy rootstocks which are now breaking freely. The late frosts have injured the foliage of the plants which are planted outside, but in a pit we have flowers yet to open. It is a valuable addition to the limited number of species known to us.

THE TURKESH HAZEL-BUT TRADE.—A considerable trade has spring up of late years between the Trebizond district and Great Britain in the article of Hazel-nuts, which are a very important source of wealth in the coast extending from a little south of Batcum to Kerassund. Upwards of \$20,000 worth per annum are shipped to England, the chief supplies of the best nuts coming from Tireboli, between Kerassund and Trebisond. Walnut trees, too, are largely grown in the forests of Lazistan, partly for the sake of the nuts, but principally for the Walnut-tree knobs, which are much in request in France.

MR. WILLIAM TAYLOR, Longleat, writes to us as follows on BIDGWAY'S HEDGE TRIMMER:—"I have great pleasure in seconding your recommendation of this implement. I have personally used one of the smaller size for several days in cutting the closely-cut Yews and similar shrubs which form our winter garden, and have found it exceedingly useful. Even the upright lines of irregular curves I have with practice succeeded in cutting perfectly with it, and this in less than a quarter of the time it would take to do it with the shears. It is a real boon to those who feel that there is some of the trimming which is not likely to be done satisfactorily by anyone but themselves, and yet can ill afford the time necessary for the purpose. For ordinary hedge-trimming it needs no skill; a lady could favourably compete with a professional armed with the famous Dunse hook. There will now be no excuse for the slovenly practice of cutting a hedge downwards."

THE LARGEST OAK IN BRITAIN.

THE Rev. Basil Edwards of Blaisdon, in asking what tree may justly claim the above title, has raised an interesting question. I presume that the reverend gentleman, who couples with his inquiry the belief that the Oak now standing at Newland in Gloucestershire is the largest at present extant, would be inclined to award the palm to the tree possessing the greatest girth of trunk. If so, I am afraid that the claims of the Newland Oak must fall before the superior dimensions of the massive bole possessed by the giant tree at Cowthorpe in Yorkshire. This Oak, I believe, exhibits the largest circumference of trunk presented by any living example of the species. It is situated in the middle of a field, about three miles from the pretty little market town of Wetherby. Hard by stands the old church of Cowthorpe, quaint and diminutive, and just across the pasture flows the clear stream of the winding Nidd. On every hand the surroundings are beautiful, and the huge proportions of this remnant of the "buried past" furnish a pretty centrepiece in as lovely a bit of rural scenery as the eye could look upon.

This tree, as may be supposed, has not failed to attract the attention of writers on old Oaks. The modern editor of Evelyn

(Dr. Hunter), in speaking of its dimensions, says they are "almost incredible." He tells us that "close by the ground it measures 26 yards in circumference. Its height is about 80 feet, and its principal limb extends 16 yards from the bole;" and, in conclusion, he states that "neither of the Oaks mentioned by Mr. Evelyn bear any proportion to the one at Cowthorpe."—("Silva," vol. ii., p. 197.)

I much regret that in a recent visit to this celebrated tree I was unable to test the accuracy of Dr. Hunter's estimate of its dimensions, as given above. Certainly the trunk is of gigantic proportions, and must at any rate approximate to the size set forth by the learned doctor, and I have no hesitation in affirming that its girth far exceeds that of the Newland Oak. Of its branches, which are said to have once extended over half an acre of ground, one only now remains. Every year its broken and weather-beaten trunk is crowned with a plentiful growth of green foliage; and some idea of the size of the roomy hollow of its stem may be gathered from an incident related to me by a Wetherby friend, in whose veracity I have implicit confidence.

This gentleman informed me that upon the occasion of a school anniversary, at which he himself was present, no less than seventy children were packed within the hollow trunk of the Oak at one time, and whilst in that position they heardly sang the National Anthem.—THOMAS B. TROWSDALE.

REIDIA GLAUCESCENS.

THE species comprised in the extremely large and peculiar natural order Euphorbiacese are remarkable for their great diversity in habit. The majority are herbaceous plants with simple leaves and insignificant flowers, and are widely distributed through temperate and tropical countries. inhabitants of dry regions, assume the appearance of Cactacoeses plants, with strangely formed succulent leafless branches and stems. Others, chiefly Crotons, are largely cultivated in our hothouses for the beauty of the foliage, and a few species of Euphorbia and the well known Poinsettia are general favourites owing to their brilliantly coloured bracts. The Phyllanthuses and Xylophyllas have flattened leaf-like branches, on the margins of which are produced bright and pretty little flowers, and are well worth cultivating; but for general elegance Reidia glaucescens can scarcely be surpassed by any of its numerous strangely varied congeners. This plant was introduced to the Boyal Gardens, Kew, from Siam in 1864 by: Thomas Christy, jun., Esq.

The genus Reidia comprises about a dozen species, chiefly natives of India, but mostly inferior in decorative value to the natives of India, but mostly interior in account intra-one under consideration, which, although of such recent intra-one under consideration, which, although of such recent intraduction, has become a great favourite with cultivators. It owes much of its gracefulness to the slender branches along which the oval leaves are arranged in a two-ranked (distichous) manner, each branch greatly resembling a pinnate leaf. From the axils of the true leaves hang the flowers on filamentous peduncles, and to a casual observer the flowers appear to spring from beneath the branches. The flowers are small and unisexual, those at the lower portion of the branches being staminate, with four deeply fimbriated sepals, and those on the upper part pistillate, with six similar sepals and longer peduncles. The sepals in both forms are of a greenish tinge towards the margin, crimson in the centre and on the under surface, the

peduncles also being tinged with red.

The plant is of easy cultivation, as it only requires a light open compost of loam, sand, and peat or leaf soil, with good drainage, and a brisk moist stove temperature. Under such liberal treatment it thrives rapidly, and as the small but pretty summer and autumn it amply repays for cultivation; in fact, even when its flowers have fallen, the graceful habit of the plant renders it very attractive and distinct for associating with other plants in groups.—L. CASTLE.

HINTS ON LANDSCAPE GARDENING .- No. 9. PLANTING ON SLOPES.

Down the head of a glen a stream of water falls, dashing and foaming among projecting rocks, its spray flashing in the sunlight with a beauty as wonderful as it is transient. The cascade is a long one, for the steep slope is some 40 feet from top to bottom; it is therefore worthy of the position, and is all the more effective from the happy manner in which its sur-roundings blend with it. The ravine trends downwards for

some distance from north to south, and when it had to be treated as an ornamental feature clothing and shelter were of especial importance about its head to the north, and also above its eastern side. Now, the soil was shallow, light, and poor; the trees selected were therefore Beech and Silver Fir, both growing freely and to a large size in such soils, bearing exposure to cold and high winds equally well, exhibiting nothing of that storm-beaten stunted aspect which most trees assume when growing under such adverse conditions, but becoming so ornamental as to form a special attraction in themselves. A few Scotch Firs and Larches were also introduced in irregular clumps along the east side, advancing boldly to the edge of the ravine at some points, at others retiring to a considerable distance, no formal lines being made anywhere. In such a soil the Larch does not become a fine tree. Growing with rapidity for about twenty years it is an excellent nurse for the permanents. nent trees, answering well however much exposed the situation may be, provided the young trees are not more than a yard high when planted and it has a little monthly attention in the first two seasons of growth. Some of them when the branches are heavy with foliage always become wind-rocked before the roots are established, and then, unless set upright and the soil made firm about the stems, they do not grow, being swayed about by every gust of wind. Prompt attention to this and to thinning as they become large enough to require it not only insures success but is profitable. Larch poles, being useful for a variety of purposes, always command a ready sale.

Planting for profit is, however, not much thought of in the

treatment of a glen or ravine and its surroundings. If it were I should have used Spanish Chestnut instead of Beech, for it cannot be too often repeated that this Chestnut answers well in a poor thin soil, growing as fast as the Beech. Yet the Beech becomes ornamental much sooner than the Chestnut. and therefore in planting for shelter as well as for effect preference was given to it. Few deciduous trees are ornamental when young, and therein lies our difficulty. To plant well it is requisite to understand the character of trees when fully developed as well as their requirements as to situation and soil; ignorance of these important points has led to many a failure.

Lower down where the glen opens out into a valley the surface was much broken, other glens ending near the same point so that there were high ridges and abrupt slopes forming an irregular but picturesque semicircle, affording many suitable sites for planting, which was so done as to impart a distinct effect here as well as to blend with that of the wide slopes of the valley beyond. A dozen or two Beeches were the only tallgrowing trees used, and these were put singly upon prominent positions, and so far apart that for a time the shrubby undergrowth surrounding them was the most important. Slowly and surely, however, did the Beeches spread their branchs upwards and outwards, and I ought to add downwards, for with plenty of space they become very beautiful, the lower branches sweeping the ground and the upper ones springing straight out from the massive trunk, the whole forming one of the finest combinations of elegance and strength in nature—pleasing even when bare of foliage, and it is to this I am desirous of calling particular attention. Few deciduous trees are so orna-mental in winter, and in extensive pleasure grounds a grove of

them makes a telling feature.

It was originally my intention to have made a plan of an ordinary kind to illustrate this paper, marking the position of a few of the most important trees with figures. This plan has gradually grown into the accompanying sketch, fig. 40, not by any means a finished one, but sufficiently elaborate to convey some idea of how ground may be broken up and rendered ornamental with water, rocks, and trees. Very few shrub groups have been sketched, but space for large quantities would be found among the trees as well as on the slopes. The slope on the right of the main stream ought only to be broken with a few clumps and isolated specimens so as not to obstruct the view from the path. The left bank may be quite clothed with shrubs wherever rocks do not occur, and there should be plenty of Ferns and ledges along the margin of the water. Avoid a superabundance of evergreen shrubs. If such a scene did not change with the seasons it would be sadly deficient in the freshness of spring, the full rich wealth of summer and the brilliant tints of autumn, all of which we look for and admire in turn. Let us be sure to have plenty of deciduous growth, no matter how brief may be the duration of its blossom or foliage, and with it enough of that which retains its foliage in winter to give warmth and greenery then. I hope soon to prepare some drawings of cascades in sections on a sufficiently

Fig. 40.-PLANTING ON SLOPES.

large scale to show how they are constructed, and also to explain the principles that should guide us in the formation of ornamental pieces of water.—EDWARD LUCKHURST.

THE OLD MARKET GARDENS AND NURSERIES OF LONDON.—No. 27.

DURING that period when English horticulture was, if not in its infancy, at least in its childhood, there was much to attract the inquiring young gardener to the west of London. He might have had access without much difficulty to the Royal gardens of Kensington Palace, the Apothecaries' Gardens at Chelsea, and to the gardens attached to Raneleigh House, Fulbarn Palsec, Holland House, to Lord Burlington's residence at Chiswick, and to other places where amateurs of high degree made experiments in nursery gardening. We might therefore expect to find that many gardeners would be led to take ground about the western suburbs near to the above, and such was actually the case. Possibly, however, they did not to the extent that seems probable with these attractions in view; but doubtless, as the nurserymen of the past, like those of the present, had to consider what were likely positions for obtaining business, there were good reasons why some preferred settling in other suburbs of London. The citizens in their holiday excursions were fond of going northward to the breezy heights of Hamp-stead or Highgate, eastward to the well-known Forest, or crossing the Thames they sought the Surrey fields and hills. Some, it is true, did go westward, following the track of the Londoner's river, but they kept near the stream in the general way, and the mighty movement westward which has been so notable in this century had not commenced. Hence we find few memories of nurserymen beyond Kensington until recent times; and though there was some land under cultivation for the London markets in the days of the Georges in the districts now to be noticed, the holders of it pursued methods of farming rather than of market gardening, where every effort is made to turn the land to best account, and to raise vegetables by fixed periods for immediate sale. Names now, or until recently, in existence between London and Acton bear witness to this. such as Shepherd's Bush Farm, Old Oak Farm, Notting Barn Farm, and Wormholt Farm, where corn was grown not long ago, and a large number of cattle, sheep, and pigs kept until the growth of the metropolis brought about a change. But we may still see cows grazing near Uxbridge road, within an easy walk of once courtly Kensington. Notting Barn Farm, the land belonging to which has now been nearly all cleared for building, was between Holland Park and Kensal Green; it is marked on most old maps of London, but has vanished in 1879. At one period principally a grass farm, we presume, subsequently the occupiers found it advantageous to devote ground to market gardening, and from growing Potatoes and Cabinges, like other farmers similarly circumstanced, they came to cultivate a variety of plants to meet the new demands of the Lendon markets. As an historian of the county tells us, that the farmhouse was surrounded by numerous barns and outbuildings, which, used at first for storing fodder, were afterwards found serviceable in other ways, it might be conjectured that they gave name to the place, but this was not the case. The public way from the Uxbridge road to Kensal Green passed formerly through the farmyard, the house of which was in the olden time a manorial residence. Knotting Bernes of Knotting Barnes does not appear on very early records, but in 1524 we read that the manor contained several hundred acres, nearly two hundred of which were wood, a remnant of the old forest of Middlesex, which once reached nearly to the river's bank at Hammersmith. For two centuries afterwards only a small portion of the land was brought under the plough, while much of the rurality of the estate remained until 1820, according to Faulkner. Describing the prospect from the heights of Holland Park in the direction of Notting Hill and Shepherd's Bush, he says that "there is a lovely view, the grassy valley towards the north appears to have undergone little change for ages, although the distance from London is not three miles. The traveller may imagine himself embosomed in the most sequestered part of the country, and nothing is heard to interrupt the course of his meditations but the notes of the lark, the linnet, and the nightingale." This was too charming to last, and another author writing of this neighbourhood before Her Majesty came to the throne, had to say that it showed recently an "accumulation of buildings." We wonder whether even he would know the place now. With that vagueness which so often annoys us in the old histories, Bowack tells us that there was formerly a Hop planta-

tion of 20 acres near the Uxbridge Road, about three miles from Tyburn, which was presumably somewhere in the Notting Barn lands, but the exact position of which is unknown. We have wondered at times why there have been so few attempts at Hop culture in the favourable positions offered by west and north Middlesers.

Faulkner states that Charecrofts, part of the charity land belonging to the district, was in 1820, or about that time, occupied by Mr. Middlemist, who had an establishment called the Cape Nursery. This we cannot connect with any nursery of the present day. Most of these about Notting Hill are of recent date. Mr. Taviner's, however, near the extremity of Kensington Gardens westward, probably represents some ancient nursery; and Mr. French's in Ladbroke Grove bear signs of age, though the land now attached to it is of small extent, yet it is turned to good account. The noted establishments of Mesers. Hopgood & Co. near Shepherd's Bush, which we remember from frequently passing it some ten or twelve years ago, has disappeared from that locality, being succeeded by houses. One line of these, called Hopgood Street, remains as a record of the floral treasures that have vanished. The firm is, however, still in existence, and flourishing I hope, having nurseries in Addison Road, Kensington, to the north of Notting Hill. Brondesbury Park, comprising some rich land well situate, was, when it cessed to be a private residence, occupied in part by Messrs. Pounce & Sons as a nursery and market garden, and as a sale of plants and implements took place there towards the end of last year we infer that the ground is to be devoted to other uses. Mr. Boller of Kensal New Town is well known as an exhibitor of succulent plants and other novelties—especially miniature plants. Shepherd's Bush, novelties especially miniature plants. named originally from a sign of an old inn of "The Shepherd in the Bush," has had its garden ground interfered with sadly of late. Many new streets have been built, and, what is even less agreeable, garden land has been converted into brick fields. No longer does Wood Lane lead to anything resembling a wood, though Wormholt Scrabs and Old Oak Common remain, and there are market gardens between here and Acton divided off by hedges, in which grow dwarf Oaks and Maples here and there, not commonly observable in London hedges. I suspect that the pretty orange-tip butterfy has almost deserted the fields in which we have frequently seen it in April, and that metallic-looking moth, the Burnished Brace, has doubtless sought a quieter abode. Some fifty years ago Shepherd's Bush was rather famous for its bee-keepers, who boasted of the quantity of honey they obtained, considerwho coasted or the quantity of honey they obtained, consucting that their bees had usually only a short season. The insect at that time probably got most of their honey, not from gardens, but from the commons northward, dotted with Heath and Furze. In 1838 an amateur of Shepherd's Bush, Mr. Salter, possessed what was supposed to be the best collection of Irides in England, many of his varieties having been raised from seed. He was also a noted grower of Beess and Dahlias. About that date Mr. Plimly had about nine scree under cultivation there. In his nurseries he produced numerous Geraniums and Dahlias; he was famous for his pineries, from which he sent many "Queens" to the market. Lawn Nursery, owned by Mr. Morgan, now overlooks the Green, situate be-tween the two main roads that run across it, and on the north side is Mr. Hart's nursery, both being of moderate pretensions

Still "stepping westward," and passing Starch Green, which has yet a little open ground, but which by its name suggests laundries rather than market gardeners, we reach first Acton and then Ealing. Acton, so say some, was primarily "Oaktown," from the Oaks that environed it, but the most of them have been felled. It is somewhat singular, however, that there should be at Bolla Bridge, Acton, a market gardener bearing the name of the place. Lyson notes that in 1792 out of the 3000 and odd acres belonging to Balling only 250 were in the hands of market gardeners. The ground thus counsel at Ealing has increased since then, consequent upon the disappearance of market gardens near London. Gunnersbury Park near Ealing is memorable as having been an early though not a trade nursery. For a long time it was famous for its Orchida, and it had early specimens of the Orange and Tree Ferns. At Ealing Dean in the present day Mr. Smith has made Cyclamens and Poinsettias his specialities, and he also sends to the market large quantities of Begonias, Cinerarias, and Fuchsias. Mr. Dean of Banelagh Road has devoted much attention to spring-flowering plants, such as Primulas, Pansies, and Polyanthuses. At Acton Mr. Reeves is a renowned grower of

Tulips; and Mr. Puttick of the same place has a nursery of August. One may for years have searched mountain and dale some repute.—C.

EFFECTS OF THE FROSTS OF 1860-61 AND 1878-79. By H. J. Lowe, F.R.S.

THE greatest cold of 1860 exceeded that of last winter by 10°; it was 6° below zero in 1860, and 4° above zero in the late frost. The present paper records the great difference in the effects in the two frosts at Highfield House, Nottingham:—

	CORON NO TENEMENT TO	ige, tidemitanem .
Name.	Frest of 1860.	Frost of 1978.

The above will sufficiently illustrate the effects of the frosts in two severe winters.

and remarkably small.

It is worthy of remark, that instead of cold killing the slugs and various pests of plants they were never known so numerous. Many hardy plants in pots were killed, such as Ivy, Pteris aquilina, &c., when they escaped if plunged in the ground.—(Report of the British Association.)

A TRIO OF NATIVE PLANTS.

THE following is extracted from a work that was reviewed on page 156 of the present volume of the Journal of Horticulture—viz., "The Isle of Arran." The plants alluded to possess considerable merit, but unfortunately the two first described are somewhat difficult of cultivation, and it is only by careful attention to the conditions under which they thrive in a native state that success will attend the grower's efforts.

"Lobelia Dortmanna.—This interesting plant blooms in

August. One may for years have searched mountain and dale for wild flowers, and never have seen this plant or any one of its species; and in consequence of having known the tribe only from its garden varieties, which are half hardy in their nature, he may have been led to associate it with what is delicate and exotic in horticulture. With what surprise and delight then does he behold the surface of the shallower waters of the lofty Loch-na-Davie (1182 feet), all dotted over with flowers which, with the exception of being lighter in hue, are in all respects identical with the lovely Lobelia speciosa of our gardens! The plant and all its leaves are several inches beneath the water; but the pale blue, airy flower, supported by an elastic leafless stem, rises several inches above the surface of the loch, and encounters uninjured the flercest blasts; for when they blow it bends before them, but—conquered yet unconquerable—as soon as they pass again it raises its head, and nods and smiles as sweetly as ever.

"Utricularia vulgaria, the great Bladderwort, has been gathered in the same loch. This plant, so beautiful in flower and wonderful in structure, grows beneath its waters. To its leaves are attached small sacs or bladders, provided with a little lid, and secured by an elastic valve opening inward. The sacs are filled with a gelatinous liquid till it is necessary that the plant should rise to the surface to expand its blossoms to the sun. At this stage it secretes a gas with which the bladders second filled, and the plant, disengaging its roots from the soil, by the help of the little bladders floats to the surface of the water. But how are the seeds to be safely deposited at the bottom of the water? The gas in the sacs is absorbed in autumn, and the little inward opening valve, up to this stage so tight, now opens—water takes the place of gas in the

bladders, and the plant again sinks.

"Drosera, the Sundew, the most exotic-looking of all British wild flowers, is, to the writer, also associated with Loch-na-Davie; for though not rare it was here his father first met with it, and such enthusiasm did it produce that he welcomed it with a shout of joy. Its flowers are white. But it is not these which made so great an impression on Dr. Landsborough, and led Darwin to style it "Queen of the Marsh—Imperial Drosera." It is the contrivance its leaves manifest, and the curious and beautiful character of their adornment. They are of a light green colour, covered with short, and fringed with longish purple hairs tipped with glands exuding crystalline globules of a sweet viscous liquid, varying with the size of the hairs they terminate. Insects, attracted by the sweetness of the liquid, are detained by the clammy mucus, while the leaf closes upon them—the hair-like fringes overlapping each other, so that by no possibility can the prisoners escape. Such is the contrivance. But to behold the beauty of the plant, see it when shone upon by the rising sun. Then all the little crystalline globules crowning the purple hairs sparkle like so many diamonds of purest water, so that no princess in fairy tale is so beautifully and profusely bejewelled as this enchanting little daughter of the marsh."

WORK FOR THE WEEK.

KITCHEN GARDEN.

Solls of a stiff adhesive character should be put up in ridges in the roughest manner possible, in order that the rain and frost may effectually pulverise it. Even on light soils this is necessary as a means of exterminating the numerous posts which were concealed beneath the surface. Previous to turning up soils that have been long under crops a dressing of gas lime would be advantageous. A light dressing only should be applied; 20 bushels per acre is a sufficient dressing, spreading it ewerly and digging it in. Globe Artichoke plants having had the decayed leaves removed, as previously advised, should be protected before severe frost sats in. Coal ashes placed about the crowns 4 to 6 inches thick, and extending a foot or more outwards, form a capital protection, but litter may be employed for covering the remaining space. Cut and remove decayed Asparagus stems, applying a good dressing of well-decomposed manure to the surface of the beds. Avoid placing too much soil on the beds so as to bury the crowns deeply. Broccoli for spring use should be laid with their heads to the north, taking out a little soil to admit the stems on that side; the stems should be covered with soil. This will check a tendency to late growth, and enable them to better withstand severe weather. Clear away all decayed leaves from Brussels Sprouts and other greens, in order to admit air and harden them against frost.

Forcing Department.—If Potatoes are required very early sets should be inserted in leaf soil for sprouting preparatory to being planted out in pots or beds; a bed with a gentle heat will be necessary for these at this season. For Asparagus, pits that admit

of a bed being formed of fermenting materials are desirable. The bed should be formed of stable litter and leaves previously thrown together and mixed, and in forming the bed tread the materials down firmly, placing 2 or 3 inches of light soil on the surface. When the temperature is between 70° or 80° the roots should be introduced and spread out, afterwards watering with tepid water. Seakale can be forced very readily in this way, but a temperature of 60° to 65° is quite sufficient, and a covering of some kind will be necessary to exclude air and ensure blanching. We, however, prefer to force Seakale and Rhubarb in the Mushroom house, fresh roots being introduced at fortnightly intervals. Chicory can also be forced very successfully in the Mushroom house. Peas are sometimes forced, but unless there is ample accommodation a house sometimes forced, our unless that is simple afforded, and the plants kept near to the light with a temperature not exceeding 50° by artificial means, the return is not commensurate with the space and labour involved. Early Premier Gem, Blue Peter, and Little Gem are the best varieties for the purpose. Beds should be made in pits and frames in readiness for early crops of Radishes, Carrots, and Potatoes. A depth of about 4 inches of light rich soil will be sufficient for the Radishes, that or a little more for the Carrots; indeed the same bed will do for both, sowing the seed in alternate rows about 4 inches apart. Early White and Early Scarlet Forcing Turnips with French Breakfast are the best Radishes, and if a long one be wanted, Wood's Frame. Of Carrots, French Forcing and Early Nantes. The best Potatoes—Veitch's Ashleaf and Myatt's. It is important where forcing operations are extensively carried on to have on hand a good supply of fermenting materials fit for immediate use. Under favourable conditions ventilate fit for immediate use. Under favourable conditions ventilate freely frames which contain Radishes, Cauliflowers, Lettuces, &c., as the more they are inured to cold the better they will endure severe' weather. Make an occasional sowing of French Beans according to the demand and space at command, sowing Mustard and Cress to maintain the supply unbroken. Where there is a house devoted to Tomatoes, a light well-ventilated structure, attention will be needed frequently to keep up a succession of bearing wood, cutting out exhausted growth and training in their place young growths which show fruit freely. The plants that here heen some time in hearing should have ton-dressings of helf lose. been some time in bearing should have top-dressings of half loam and half manure as fresh roots appear on the surface, watering as may be necessary with weak liquid manure. A temperature of 60° to 65° at night and 70° to 75° by day will be necessary to ensure their continuous bearing.

Mushroom House.—Continue to make up successional beds of prepared material. Early beds will now be coming into bearing, and should be watered with tepid water. See that the surface of the beds in any stage does not become extremely dry, but avoid making them overmoist. A moist atmosphere will need to be maintained, sprinkling the walls, paths, dc., occasionally, and a temperature of 55° to 60° secured. Though 5° less will add to the quality of the Mushrooms, yet the temperatures named are advisable where the house is employed for forcing Rhubarb, Seakale, dc., as the latter, from the backward state of vegetation this year, will require more heat to excite them as well as more time to develope.

HARDY FRUIT GARDEN.

Planting fruit trees should be proceeded with as soon as the majority of the leaves have fallen. A few hints as to the most suitable aspects and varieties may not be unacceptable. Walls with a southerly aspect answer for Apricots, Peaches and Nectarines, Figs, and Vines, though with proper glass houses the culture of Vines against walls is not advisable. Nevertheless, with glass copings there is no reason why in favourable seasons fair crops of Grapes should not be obtained from Vines on walls. The followcrapes should not be obtained from vines on wails. The following is a selection of the best varieties for the purpose named:

Apricots: Moor Park, Oullins Early, and Shipley's. Peaches: Hale's Early, Dagmar, Dr. Hogg, Grosse Mignonne, Violette Hâtive, Royal George, Noblesse, Bellegarde, Barrington, Priftcess of Wales, and Walburton Admirable. Nectarines: Lord Napier, Elruge, Violette Hâtive, Balgowan, Pitmaston Orange, and Albert Victor. Brown Turkey is the best Fig, though the Brunswick is well suited for the nurrose: it grows so freely as to require more well suited for the purpose; it grows so freely as to require more space—a high wall or building. White Marseilles is a fitting companion for Brown Turkey. Vines: Early Accot Frontignan, Royal Muscadine, Early White Malvasia, Miller's Burgundy, Espiran, Black Cluster, and Cambridge Botanic Garden, with Black Hambridge Botanic Garden, with Black Palla Albertan May Duke burgh. Cherries: Early Jaboulay, Belle d'Orleans, May Duke, and Black Tartarian. Plums: July Green Gage, De Montfort, and Green Gage should be planted against south walls, as they are then earlier and much improved in size and quality. Jargonelle Pear, with Marie Louise, should be planted against every aspect, Fear, with mane Louise, should be planted against every aspect, so as to afford a prolonged succession of those finest of sutamer and autumn Pears. East aspects suit such Plums as Green Gage, McLaughlin, Jefferson, Kirke's, Transparent Gage, and Coe's Golden Drop, Ickworth Imperatrice and Late Rivers being valuable for their lateness. Similar aspects suit Cherries. To those previously named may be added Elton and Bigarreau Nameleron. West aspects appears for Pears but the support and Napoleon. West aspects answer for Pears, but the summer and autumn Pears, as Beurré de l'Assomption, Souvenir du Congrès, Williams' Bon Chrêtien, Beurré d'Amanlis, White Doyenné, Louise

Bonne of Jersey, though improved in size and appearance, are frequently not so good in flavour as those grown in the open. Beurré Superfin, Louise Bonne of Jersey, Hacon's Incomparable, Durondeau, Marie Louise, Beurré Diel, Van Mons Léon le Clert Passe Colmar, Beurré Bachelier, Beurré d'Aremberg, Glou Morceau, Winter Nélis, Joséphine de Malines, Beurré Rance, Ne Plus Meuris, and Bergamotte d'Esperen are improved by growing against a wall. Beurré Clairgeau may be grown for its beauty and Duchesse d'Angoulème for size, Chaumontel and St. Germain requiring both a south aspect and a warm sandy soil. North aspects answer for Morello and other Cherries. Jargonelle, Williams' answer for Morello and other Cherries. Jargonelle, Williams Bon Chrêtien, and White Doyenné Pears succeed against a north wall; and culinary Plums, as Early Prolific, Prince Engleber, Mitchelson's, White Magnum Bonum, and Victoria. Apples for Dwarf Bush Pyramid or Espalier Culture: Irish Peach, Devonshire Quarrenden, Kerry Pippin, King of the Pippins, Cox's Orange Pippin, Court of Wick, Ribston Pippin, Margil, Keddlestons Pippin, Reinette de Canada, Cockle's Pippin, and Sturmer Pippin, The above are for dessert. The following are culinary varieties:—Keswick Codlin, Lord Suffield, Stirling Castle, Cox's Pomona, Cellini, Small's Admirable, Winter Hawthornden, Yorkshire Greening, Warner's King, Norfolk Bearer, Alfriston, Dumelow's Seedling, and Hambledon Deux Ans. Pears for Bush, Pyrassid, or Espalier: Summer Doyenné, Jargonelle, Williams' Bon Chrétien, White Doyenné, Comte de Lamy, Seckle, Marie Louise, Urbanista, Louise Bonne of Jersey, Doyenné du Comice, Beurré Diel, Beuré d'Aremberg, and Zephirin Grégoire. Plums for Dwarf Culture; July Green Gage, Green Gage, Oullins Golden Gage, Jefferson, Kirke's, and Guthrie's Late Green. The above are dessert. For culinary Early Rivers, Gisborne's, Mitchelson's, Victoria, Prince Englebert, and Belle de Septembre. Morello Cherry is well worth a place in every garden, as it succeeds under dwarf culture; but the others, unless grown as espaliers, are difficult to protect from birda. Apples to be Grown as Standards for Orchards:—Culinary: Keswick Codlin, Stirling Castle, Emperor Alexander, Golden Noble, Bymer, Blenheim Pippin, Kentish Fillbasket, Vorkshire Greening, Dumelow's Seedling, warner's King, Northern Greening, Bedford. Seedling, and Hambledon Deux Ans. Dessert Apples for Orchards: Irish Peach, Whorle Pippin, Worcester Pearmain, Kerry Pippin, Cox's Orange Pippin, Gravenstein, Ribeton Pippin, Reinette de Canada, Cockle's Pippin, Dutch Mignonne, Golden Bon Chrêtien, and White Doyenné Pears succeed against a north Orchards: Irish Peach, Whorle Pippin, Worcester Fearmain, Kerry Pippin, Cox's Orange Pippin, Gravenstein, Ribston Pippin, Reinette de Canada, Cockle's Pippin, Dutch Mignonne, Golden Russet, and Sturmer Pippin. Pears for Orchard Planting: Jargonelle, Williams' Bon Chrétien, Louise Bonne of Jersey, Beurré de Capiaumont, Marie Louise, Swan's Egg, and Beurré Diel, with Catillac for stewing. Plants for Orchard: Early Rivers, Early Orleans, Gisborne's, Victoria, Mitchelson's, Kirke's, Prince Englebert, White Magnum Bonum, Winesour, Wyedale, and Cluster bert, White Magnum Bonum, Winesour, Wyedale, and Cluster Damson. For planting against walls full-trained trees—i.e., the trees two, three, or more years trained, are every way preferable to trees of less size and age, as they not only come sooner into bearing, but do not make such vigorous growth. Plant as early as the condition of the trees will admit, so as to give them the benefit of the comparative warmth of the ground, and thus allow of their establishment before the ground is soddened and cold.

Wherever the condition of fruit trees is such as to render an examination of their roots advisable, it should be attended to whilst the weather is favourable. Sickly trees are frequently restored by having their roots brought nearer to the surfarestored by having their roots brought nearer to the surface, and encouraged by laying-in fresh loam with a small portion of thoroughly decomposed manure, so as to encourage the formation of new fibres; and if the soil be too tenacious a portion of road scrapings, old mortar rubbish, or other gritty material may be added with advantage; but if too light an admixture of clay or marl will be advantageous. Planting fruit trees should be proceeded with, as the earlier they are planted the better; and although most descriptions of hardy fruit may with more or less success he grown on nearly all kinds of soil the better the soil success be grown on nearly all kinds of soil, the better the soil the better will be the quality of fruit produced. In most instances draining is absolutely necessary, heavy and retentive soils needing it more than light soils; in addition to which a portion of light soil, road scrapings, burnt clay, and wood ashes or charred refuse soil, road scrapings, burnt clay, and wood asnes or charted reuse added will be of benefit; and in planting the trees, whether dwarfs, standards, or espaliers in such soils, slightly raised hillocks for planting on should be made. Light soils, on the other hand, should have well-pulverised clay or strong loam incorporated with the original soil. Pruning Apple, Pear, Plum, and Cherry trees should be proceeded with whenever the weather is favourable; but where summer pruning has been practised there will be little to do at this season. Fig trees against walls should be unfastened, the branches tied up in bundles, encased in clean straw, kept together with mats; or the trees may be allowed to remain on the walls and the surface thatched with dry fern, straw, mats, or other materials, mulching over the roots with manure.

STRAWBERRIES IN POTS.

Strawberries intended for early forcing should be placed in frames or pits in a sunny situation, and have air abundantly on all favourable occasions. The general stock, now that sharp frosts may be expected, should be plunged in ashes in a sheltered situstion, where they will winter quite as well as those afforded the protection of a cool house. Though the demands of the plants

for water will be considerably lessened, supplies must be afforded make their appearance in a moist fernery in considerable numbers as necessary to keep the soil thoroughly moist. Autumn-bearing plants will require to be near the glass, and a free circulation of air will be necessary. The temperature will require to be kept at 55° to 60° at night and 10° more in the daytime.

FRUIT HOUSES.

Pines.—Properly heated and ventilated pits or small houses afford the most suitable atmospheric conditions for Pines, but afford the most suitable atmospheric conditions for Pines, but the closeness of these structures at this season necessitate strict attention to the ventilation, or the plants become drawn and weakly. For young stock 60° at night, or a few degrees less in severe weather, and 65° by day from fire heat is suitable. Keep the plants near the glass, and allow plenty of space. The bottom heat should be kept steady at 80°, avoiding too much moisture in the atmosphere, and water whenever the plants become dry with weak liquid manure. Suckers on the stools of the plants after the fruit is cut may be preserved until March fruit is cut may be preserved until March.

Cucumbers.—Plants that have been some time in bearing will be invigorated by receiving a top-dressing of turfy loam, to which may be added a sixth of charcoal, surfacing with an inch of short decomposed manure. See that the soil is not too dry, guarding against over-watering, but when water is necessary give a thorough soaking with water at the same temperature as the house. Ventilate moderately whenever the weather is favourable, but avoid lowering the temperature excessively, as a chill is alike injurious to plants and fruit. The temperature should be maintained at 65° at night, and in severe weather 60°, and 70° to 75° by day from fire heat, advancing 10° to 15° with sun heat.

PLANT HOUSES.

Orchids.—All watering and syringing must be done by twelve o'clock, which will admit of the superabundant moisture being dispelled by the time the temperature lowers in the evening, dispelled by the time the temperature lowers in the evening, which is of the greatest importance, for a wet atmosphere with a cold temperature will cause disease. A little ventilation may be necessary on warm days to prevent the temperature rising too high. Cattleyas and Dendrobiums should not have any water at those on blocks or newly imported. Odontohigh. Cattleyss and Dendrobiums should not have any water at the roots, except those on blocks or newly imported. Odontoglossums Alexandre and O. Pescatorei, with others of the same
type growing vigorously, will require a good supply of water,
damping overhead on fine mornings with a syringe or a fine rose.
Plants in flower may be removed to a drier atmosphere. Odontoglossum leopardinum is a grand variety of O. Insleayi, flowering at
this season, and Pilumna fragrans grandifiora is one of the most
charming at the dull season. The period at which any of the
plants begin to grow is the best time to repot them, placing them
in the most favourable position in the house. Miltonias may be
repotted, and shallow pans are the most suitable for their growth. in the most favourable position in the house. Miltonias may be reported, and shallow pans are the most suitable for their growth, as they require a liberal supply of water. Any plants hanging near the roof should be lowered to quite a foot from the glass, so as to prevent their being subjected to alternations of temperature. Plants of Dendrobium nobile that have completed their growth and are swelling the buds may be placed in the East Indian house, and with a damping overhead on fine days they will be in bloom by the new year, very little water being given at the roots until they begin to grow. Plants coming into flower or pushing up their spikes should be thoroughly exposed to light. Anæctochili require particular care; a little air must be left on the frames or

require particular care; a little air must be left on the frames or bellglasses, and the glass kept clean, watering only sufficient to keep the sphagnum a little moist.

Stove.—Ixoras, Dipladenias, and Allamandas afford a large quantity of flowers for cutting, but it is necessary that the temperature be not below 65° at night. The majority of stove plants do better in a temperature of 5° to 8° less at night at this season, and the atmosphere a little less moist. It is a great mistake to have the atmosphere a little less moist. It is a great mistake to have a large house, or if the house be large a partition or two put in would admit of all being accommodated. Winter-flowering plants, such as Poinsettias, Sericographis, Plumbago rosea and P. coccines superba, Aphelandras, Centradenias, Centropogons, Kranthemums, Buphorbia jacquiniæflora, Thyrsacanthus rutilans, &c., succeed best in a low span-roofed house or pit, where they can be kept near the glass. Winter-flowering Begonias require plenty of light and liquid manure occasionally. Plants that are partially deciduous—as Clerodendron Balfourianum, Aristolochias, Bougainvilleas, and Allamandas—may be allowed to go for weeks without water, but the wood must not be allowed to abrivel. Stephanotis, Combretum, Hoya, and similar plants should be kept dormant by dry treatment, but the foliage must not shrivel or become very flaccid, or it will fall off. Evergreens—as Ixoras, Francisceas, Gardenias, Tabernsevontanas, &c.—must have a sufficient supply of water to maintain the foliage in good condition.

Gardenias, Tabernserontanas, &c.—must have a sufficient supply of water to maintain the foliage in good condition.

Feras.—The greenhouse species and varieties require a temterature of from 40° to 45°, and the exotic species 55° to 65°, supplying no more water at the roots than is requisite to keep the plants from suffering. Where a number of Adiantums and Pterises are required for cutting or decorative purposes they should be kept near the glass to render them robust, and if grown in loam they will be stronger than when grown in peat. At this season they should have as little excitement to growth as possible. The varieties most in demand, as decorative plants and furnishing frends for cutting, are Adiantums and Pterises, which

from self-sown spores. These when large enough to handle should be taken up, potted in the smallest pots (thumbs) in a compost of loam, one-third of which should be small crocks, which will keep the soil from becoming sour before the plants produce rocks.

TRADE CATALOGUES RECEIVED.

TO CORRESPONDENTS.

_ All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written en one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

PLANTING A YEW HEDGE (J. S.).—We should obtain the shrubs at once and plant them as speedily as possible after their arrival, watering them thoroughly if the soil is at all dry. Care should be taken that their roots are not long exposed to the air, especially if the weather is dry during their

VENTILATING CONSERVATORY (M. W. T.).—We should prefer to have the north and south ventilators arranged to open separately. During many weeks in winter and early spring north ventilation would not be required but slight openings on the south side would be very beneficial. The north ventilators would only need to be opened in summer, and would then be

PLANTING VIOLETS '(Agricola).—You may plant the Violets now removing them with as much soil attached to the roots as possible. You do not say whether the plants are established and ready for flowering or not; if they are, a little glass protection such as frame lights or handglasses placed over them would be advantageous. The end of March or beginning of April, according to the weather, is a good time for forming beds of Violets by planting small offsets. If you send 2s. 8d. in stamps to the publisher and order the manuals you name in your letter, they will be sent to you by post.

ROSES NEAR LONDON (H. T. P.).—We cannot undertake to answer your question. You had better visit a few of the nurseries where Roses are largely grown, and you will thus gather much information that will be useful to you.

WOOD ASHES FOR LAWNS (A Constant Subscriber).—An application of wood ashes sufficient to form a thin covering to the lawn would stimulate the growth of grass and improve the lawn considerably. A dressing of soot during a still showery day in the spring would further be of great benefit in improving the turf and imparting a darker green appearance to the lawn.

ERRATA.—In the article on "Grapes Without Fire Heat," in our last issue, on page 371, column two, line twenty-eight, for "speedily," read "thoroughly;" and in line thirty-four, page 384, of the article headed "Rose Season," the word "these" societies should read "three" societies.

Season," the word "these" societies should read "three" societies.

PLANTS FOR WINDOW BOX (H. T. F.).—Small plants of Retinosporas, such as R. plumoss surea, R. pisifera, and R. ericoides, planted thinly have a very elegant appearance and will last for one season in London. Associated with them should be plants of suitable size of the bright-leaved Ruonymuses, such as R. japonicus aureus, E. aureus variegatus, E. latifolius variegatus, and E. radicans. Small-leaved variegated Ivies are also very suitable for hanging down the front of the boxes. Skimmia japonica and Fernettly mucronata are pretty berry-bearing shrubs suitable for the purpose required, Between the shrubs bulbs of various kinds—Hyacinths, Tulips, Snowdrops, Narcissuses, Croonses, and Scillas, should be planted, also such plants as Daisies, Alpine Auriculas, Primroses, and dwarf Wallifowers. All the plant named will also thrive in a London garden except the Retinosporas; but for town gardens few shrubs are more satisfactory than Aucubas, many of which have extremely handsome foliage, and produce their richly coloured fruits in profusion. fruits in profusion.

Club Root (W.J.~C.).—One of the best remedies that you can apply now is to dig fresh gas lime into the soil at the rate of about 20 bushels per scre. See reply to "B. T. J.," on page 355 of last week's issue.

PLANTIME CROCUSES (J. L. A.).—You cannot plant them too soon nowIf you defer planting until December many of the growths which have
already issued from the corms will probably decay. It is not a good plan to
make holes with a pointed dibber and place the corms in them. Drills are
much preferable, as the corms can then rest on the soil, which is not
always the case when planted with the dibble.

PRIMING VINE IN GROUND VINERY (F. I.).—The Vine, having extended to the end of the vinery, should be cut back to within about 2 feet of the end. Stop the shoots one or two joints beyond the fruit, keeping the laterals closely stopped to one joint. The water coming in at the ridge will be injurious, especially when the fruit is ripening, as it will cause a moist atmosphere when it is desirable to have a dry one.

CUTTING ARBOB-VITZE (Idem).—The present is not a suitable time to

HEATING A GREENHOUSE (Fork).—Your house may be heated in the manner you show in aketch—viz., with the pipes fixed at the lower part of the roof: but could you not sink the stokehole so as to admit of the pipes heing placed beneath the stage? It would be an advantage to have the piping along both sides of the house, so as to secure better diffusion of the heat through the structure: for though the mixing secure. heat through the structure; for, though the piping answers very well on one side of a lean-to, they are not so effectual on one side only of a span.

DEBEGING A LAWN WITH SALT (T. C. J.).—The salt would no doubt be efficacious in destroying slugs, a dry time being chosen for its application. Defer the operation until spring, and then apply equal proportions of nitrate of sods and salt at the rate of 2 hs. per rod (50) square yards). If the ground be heavy or deficient of calcareous matter 4 tons of lime per acre ould be a good application, applying it in March.

TOMATOES NOT SETTING (A Novice) .- We can only account for the fruit TOMATOES NOT SETTING (A Novice).—We can only account for the fruit not setting from the atmosphere being kept too close and moist, the ventilation not being free enough. The flowers are very puny, and would no doubt come stronger and set more freely if the roots are supplied with weak liquid manure. Leave the ventilators slightly open constantly at the top of the bouse, and when external circumstances admit ventilate freely. Tomatoes, though they grow and show flower freely, do not set well in a close atmosphere. Keep the plants you have for fruiting at Easter, or if you cannot do that take cuttings from them now; they strike freely in gentle heat. If you raise plants from seed sow at once, and when the plants are up keep them well near the glass, shifting into larger pots as they require it, potting firmly, and instead of using large pots faed the plants with liquid manure.

WATER LILIES (Paddle).--When the plants have grown so as to become crowded the flowers are small and not so freely produced as when they have more space. Thin them well out in spring so as to admit of space for the foliage, which will strengthen the plants and induce stronger and freer

LILIUM AURATUM (*Idem*).—It is usual for large bulbs to decrease in size especially if allowed to carry their full crop of flowers the first season. It is much better to select small bulbs, which do not feel the loss of the roots nearly so much as larger bulbs.

WINTERING TUBEROUS BEGONIAS AND GLOXINIAS (Idem).whereking Tuberous Becoming an O GLOXINIAS (idem).—Place the tubers in occoa-nut refuse a little moist so as to maintain their vitality, or they may be kept in the pots with the soil a little moist but not wet, nor on the other hand dust dry, or the roots are any to become farineceous and decay when subjected to heat and moisture. They must be kept safe from frost. Gloxinias should be kept in a temperature of 45° to 50°.

REMOVING HORSE CHESTRUT (A. R.).—Remove the soil from around the stem as much as you possibly can, exposing the roots to the fullest extent practicable, and then cut them off as low down as you can, in which case there will not be any or little fear of shoots arising from the roots, as would most likely be the case were the tree felled at the surface.

ROSE ELECTION (R. J. Clarke).—In Nos. 862 and 218 yeu will find the results of the poll of two Rose elections. The numbers can be had from the publisher in return for \$\frac{1}{2}d\$, each in postage stamps.

FRUIT TREES FOR GARDEN (W. Ball).—If you will state whether you require the Pears for growing as standards, bushes, or walk, and the Apples for dessert or culinary purposes or both, we will endeavour to name those that are likely to meet your requirements.

VINES UNHEALTHY (R. H. T.).—As the border has been made under the VINES UNHEALTHY (R. H. T.).—As the border has been made under the supervision of a competent man it has probably been well drained and formed of suitable compost; assuming that to be the case we can only attribute the unsatisfactory condition of your Vines to overcropping, or to the canes not having been out back sufficiently when young. If the roots are healthy and yet the laterals weak you would obtain stronger canes by cutting the Vines down to the base of the rafters, shortesing the growths that are made after they are matured, leaving only a length of 3 or 4 feet at each winter's pruning. You might cut down a portion of the Vines at a time if you object to being without fruit for a season. Perhaps if a competent man inspected the Vines he could suggest a better means of ranovation. The "Vine Manual," published at this office, 3s. 2d. post free, will afford you much useful information. afford you much useful information.

NAMES OF FRUITS (C. H.).—The Pear is Urbanists, the Apple Red Ingestrie. The Plum we do not recognise.

gestrie. The Plum we do not recognise.

NAMES OF PLANTS (J. C).—1, Specimen too withered for identification;
2, Fuchsia fulgens; 3, Chrysanthermum coronarium. (A. Boyle).—18 is a species of Mesembryanthermum, and its not flowering is probably due to over-luxuriance. Place the plant in poor soil and keep it dry. (J. G.).—The shrub is Clethra shrifolia. (R. S.).—The heaf is that of a Hoys, probably H. carnosa. (G. P.).—1, Cassia corymbosa; 2, Kerria japonica flore-pleno; 3, Lobelia cardinalis; 4, Centranthus ruber; 5, Resembles Pyrethrum alpinum; 6, Aster multiflorus. (A. Gonstant Reader).—Coronilla giance. (A. W.).—1, Cheilanthes elegans; 2, Selaginella Kraussiana.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

NITRATE OF SODA AND ITS USAGE AS A MANURE (Continued from page 375.)

In continuation of this subject we wish to state that nitrate of soda for many years has been greatly adulterated, often by the addition of common salt, by the vendor. When nitrate is selling at £18 to £14 per ton or upwards it is easy for the manure agent to secure a large profit by the addition of salt, and this when mixed is not easily ascertained except by analysis. We therefore advise the home farmer to purchase by analysis or by a guarantee

cut Arbor-Vites 8 or 9 feet high into the form of a hedge. It should be done in early April, or before they begin to grow, so as to admit of their becoming furnished with fresh growth before winter. -that is to say, in every hundred part of the salts minety-five parts shall be pure nitrate of soda. The 5 per cent. impurities consist of common salt, and traces of sulphate of soda, magnesia, sand, and moisture. Presuming that nitrate of soda contained 5 per cent. of impurities, we should then have 15.64 per cent. of nitrogen, which is equal to 18.98 per cent. of ammonia. One thing will be noticed, that although the adulteration of the nitrate is effected by the addition of common salt, it is not injurious as the experiments we have given show; but to have the full advantage of both nitrate and common salt we must buy them separately, because the latter will always be cheap, hence the extraordinary advantage to the manure seller who adds salt to his nitrate.

> We must now refer to the soils and climate where the nitrate is likely to prove most valuable. The best soils—that is to say, the most holding and strong loamy land, will give the best return for the application of nitrate whether the soil is cultivated or lying in pasture or meadow, likewise on clovers and field grasses; and the effect on mangolds is good, because it gives so much growth of leaves, and enables the plants to derive a large portion of ammonia from the atmosphere. For the cereals, however, it is extremely important that the land whereon they are grown should be a southern or western aspect, for upon land facing the north or north-east they are much more subject to blight by the unfavourable action of the temperature when the growth has been stimulated by the action of nitrate. Therefore under such circumstances it is imperative when corn is sown where the aspect is unfavourable to use a larger admixture of salt and mineral phosphate manures. It must be observed that the effect of nitrate upon the cereals is to produce a broad flag, which under the circumstances described may be injurious, but in the growth of vegetables and fodder crops it will be just the reverse. It is interesting to know that although in the event of heavy rains, nitrate being so soluble that there must be some loss, yet by experiments and calculations it is found that the rain itself supplies in the course of a year nitrogen equal to a certain quantity of nitrate of soda. It is, however, proved that nitrate acts best in a dry summer with plenty of smshine; for although it is shown that the loss of nitrogen from the land is very considerable for every inch of rain, which is about 101 tons per acre, yet we have a compensation, particularly in those seasons when thunderstorms prevail by the ammonia, &c., which is conveyed by the rain to plants. Hence we see the fresh vigorous appearance of our crops often perceptible after thunderstorms, and this is more particularly shown in vegetable produce than the cereals, and is due to the small amount of valuable manure the crops have received, in addition to the refreshing effect of the rain.

Experiments of great importance were tried at the Royal Agricultural College farm at Cireneester in 1862, under the suspices of Dr. Augustus Voelcker, with top-dressing upon wheat in a field of land moderately stiff in texture but well drained. One of the chief objects of these experiments was to ascertain in what proportion nitrate of sods is most economically applied as a topdressing for wheat. For this purpose 1 cwt., 21 cwt., and 8 cwt. of nitrate respectively were used per acre, in each case mixed with twice its weight of common salt. The result showing that the larger application produced a corresponding increase in corn. For whilst 1 cwt. of nitrate and 2 cwt. of salt gave an increase of 93 bushels, 11 cwt. of nitrate and 8 cwt. of salt gave an increase of 12g bushels of corn, and 2 cwt. of nitrate and 4 cwt. of salt gave an increase of 182 bushels. Thus for each half hundredweight of nitrate an additional increase of nearly 3 bushels of wheat was obiained. Although these may be the results in a favourable season, yet in a wet season and upon land of a bad or north sepect the chances are that the crop would go down and the corn become blighted. On light land, such as sand and gravel or light chalk, we consider guano is often preferable to nitrate of sods and salt, because guano supplies the phosphates and alkalies as well as nitrogenous matters. Nitrate of soda is efficacious in virtue of its nitrogen alone, and requires the addition of soluble phosphate to

bring out its full advantage. Hr. Lawes, in his experiments upon growing wheat for twenty years in succession upon the same land, found that the largest crops were obtained when mineral and nitrogenous manures were employed together. The average yield of corn during the twenty years in the unmanured portion was 16½ bushels, with farmyard manure it was 32½ bushels, with artificials supplying both nitrogen as well as the phosphate and alkalies 35½ bushels, but by using mineral manures alone the average yield of twelve years was only 18 bushels 1½ peck. The field whereon these experiments were carried out at Rothampstead is a somewhat heavy loam with a subsoil of clay resting on chalk. In later experiments Mr. Lawes found by the continuous growth of barley that the results correspond in many respects with those obtained from the growth of wheat. There is no doubt that the increase of straw will follow a full dressing of nitrate; the only thing to be guarded against is the straw being so bulky as to go down, in which case it is sure to injure the sample of corn, more especially of barley, which is so much dependent for its value as malting grain. For oats perhaps no corn gives a better return for nitrate of soda dressings mixed with phosphates and salt. We know many experiments which could be related of the advantage of nitrate of soda, &c., as a manure for pasture land,

We know many experiments which could be related of the advantage of nitrate of soda, &c., as a manne for pasture land, but from our own experience we recommend 1½ cwt. of nitrate and 3 cwt. of mineral or bone superphosphate per acre for ordinary grass land, except low-lying meadows where guano would answer best, but upon any dry pastures resting on sand, stonebrash, gravel, or light chalk, 3 cwt. of common salt should be added to the abovenamed mixture. A very advantageous way of making use of nitrate of soda in our opinion is its application to early fodder crops, such as trifolium, rye, vetches, and such like, which are required for early use. We have seen it advance these crops nearly a fortuight, a matter of the highest importance, especially in a late season. Nitrate may also be used more largely, say 2 cwt. per acre, on fodder crops, because the land is cleared earlier for succeeding crops such as mangolds, Swedes, cabbage, and carrots, and the residue of manure will prove of great value to any crop which may follow. There is, however, a special value in the liberal use of nitrate alone upon Italian rye grass, especially upon chalk fill farms without water meadows, for we can obtain valuable crops of this grass ready for feeding after a mild winter as early as the month of February. After having applied an extra quantity of nitrate for the purpose of forcing on the crop we need not be afraid of its being lost in its effect upon the succeeding crops; for Mr. Lawes found in the growth of barley for twenty years, when he used 275 lbs. of nitrate of soda, and then on another plot he put 550 lbs. and thus gave it a double dressing. What is remarkable the result of this dressing, because in fourteen years after, so far from the nitrate of soda having been exhausted or washed out of the soil, where the larger quantity was used it produced a better crop for fourteen years afterwards than the part where the smaller quantity had been used. We know some land agents who frequently object to the tenants applying nitra

WORK ON THE HOME FARM.

Horse Labour.—This is now going on most effectually, for the dry and dull weather we have experienced in the last week of October and first week of November has enabled the home farmer to sow the land with wheat. However, in consequence of the wet summer the heavy lands are still very close and work badly, yet upon all dry and friable soils the land is now in capital condition to receive the seed. A heavy season is best if the weather only proves favourable for drying the surface after drilling the wheat; on the other hand, should heavy rains succeed and run the land together it will exclude the air, and this year as the seed is very small and imperfectly ripened the young plants will be likely to perish in the land. The work of the farm has been so long delayed by adverse weather that it will be difficult to sow a full complement of wheat before Christmas upon strong land should the weather prove ever so favourable; for the time when wheat-cowing ought to have been proceeding, the winter vetches, winter beans, &c., required to be sown, after having been delayed beyond the asual period. We find on looking over the heavy land farms that it will be quite impossible to sow the usual quantity of wheat, for the fallows intended for that crop never could be made in numerous instances, although steam power has been available at every interval of dry weather. The home farmer must, however, in such

cases change the course of cropping, and allow the unfinished fallows to be again prepared in the spring, and be sown with barley should the spring be favourable for cleaning the land; otherwise the fallow process must be continued and the land seeded to root crops, or a succession of mustard crops, vetches, 406, and be seeded to wheat the following antumn.

seeded to root crops, or a succession of mustard crops, vetches, see, and be seeded to wheat the following autumn.

Hand Labour.—Cutting and plashing hedges will now be commenced, also trimming those which have been neglected from any cause. Border grass or that found in the plantations should be cause. Border grass or that found in the plantetions and cut, as these materials make capital covering for heaps of mangolds, carrots, &c., which may be required to be preserved during the covering for heaps of the covering fo golds, carrous, et., which may be required to be preserved during the winter, and almost equal to seaweed. Upon some farms with little straw grown it is important to know that atraw may not be required at all, the earth covering being laid on the grass or sea-weed being sufficient. Cutting underwood may also be commenced west bang sundent. Outsing underwood may also be commenced now in the coppiess and hedgerows; the materials will always be required on the home farm—first for hurdle wood, engaging to have the hurdles made on the spot at so much per dozen, also spar wood may be selected, taken to the farm, and made up into spars during bad weather in the winter. All the strongest and roughest of the white and black thorns may be reserved, together with stout stakes for making fences, and in certain districts where there are but few live fences this is important. The remaining portion of the underwood will be made up, some into stout faggots and the lightest brushwood into kiln and other bavins adapted for placing under corn or hay stacks. Where there is common or rough land upon the estate bearing fern, rushes, dc., these should be out carefully and kept as bedding, if not required to assist in covering-in the heaps of roots. As bedding for young stock it is valuable, for it not only saves straw, but we have the evidence of Dr. Voelcker that ferns contain valuable substances as addition to the dung heap, particularly when cut in the summer whilst the sap is in the stems. In the localities of commons, forests, &c., where the poor have rights, ferns are much used and approved as where the poor have rights, terms are much used and approved as bedding for both horses, cattle, and pigs. The cattle men and shepherds will now be engaged in root-feeding the fatting bullocks and shees. In case of change of food either from turnips to Swedes, or from Swedes or turnips to mangold, it is of the greatest consequence to the health and benefit of the animals that any sudden change of food should be avoided. When going out of one field into another a few cartleads of each kind of roots may one field into another a new cartieness or essen kind or roots may be exchanged, so that the animals may eat mixed food before leaving one field and for a short time after entering another. This observation applies to sheep in open field feeding, but it is equally desirable that cattle in the boxes should not be put upon a change of roots suddenly, but have a mixture before going on to feeding of another sort of roots. It should be recollected that any disturbance of the health of the stock results in the loss of so much food, and any check to their health means so much less meat made. Cabbages now are the best food both for young stock as well as Cabbages now are the best food both for young stock as well as the milch cows, and these they may have on the pastures if dry, for there will still be some grass which, together with air and exercise, is favourable for their health. The early-herned ewes will now be lambing, and together they may with the lambs run upon the clover seeds at daytime, but should be taken to the wheat eddishes at night time, as it is much warmer lying for the young lambs, for we have known frequently cases of cramped and crippled lambs when lying on the clover at night time if the weather is frosty, and the lambs never recover.

THE MANUFACTURE OF BUTTER.

It has been considered a settled point in England, and more especially in Ireland, that in order to carry on dairy farming it is absolutely essential that all or most part of the land occupied as dairy farms shall be in permanent pasture. In the last number of the "Royal Agricultural Society's Journal" Mr. Jenkins shows that in the dairy districts of the north-west of France only a very small propertion of the land is in permanent grass; and he considers it is "necessary to draw particular attention to this point, because the excellence of the French product has hitherto been attributed chiefly to the alleged superiority of the pastures of Normandy, whereas most of the butter imported into England from France and other foreign countries is made in districts where arable land dairying is the rule, and permanent grass dairying the exception." In the most celebrated dairy departments of Normandy "much less than one-fourth of the whole cultivated land is in permanent grass of all qualities," whilst in other departments the proportion of permanent grass is one-fifth, one-sixth, and even as low as one-tenth.

In 1877 the amount paid for French butter imported into England was £8,654,488, which was rather under the rate of some previous years. It is, however, an enormous sum of money to send out of the country for an article which is actually a staple of home manufacture, but which, from carelessness or other causes, is inferior to that of foreign make. The three and a quarter millions sterling expended in the purchase of fresh butter is just so much loat to the English and Irish dairy farmers, and it is surely worth while to try whether some portion of the golden stream, if not the whole, may not be diverted into home channels

instead of supinely permitting it to enrich other countries. French dairy farmers possess no special advantages as regards rent or wages. The better classes of land rate at 30s. to 50s. a statute wages. The tetter classes of rand rate at 50s, a statute acre—and wages of agricultural labourers are from 2s, to 2s, 6d, a day, without food, and from £16 to £20 a year with food, besides lodging in the stable or cowhouse. Mr. Jenkins attributes much of the success of French dairy farmers to the fact that amongst the small farmers two or three of the children, who constitute a large family in France, work together for the common benefit. He says, "To this fact must in some degree be ascribed the success of the French tans fact must in some degree be ascribed the success of the French farmers in producing butter, and especially soft kinds of cheese of delicate flavour, and therefore possessing a high market value. Under no other circumstances probably would so much care be bestowed on the making, and such constant supervision in the curing, to say nothing of the delicacy in packing, of these highly susceptible and easily perishable articles of commerce." We have much the same conditions existing in Ireland amongst our small farmers; but, generally speaking, similar results have not been produced as those which Mr. Jenkins describes. There may be reasons for this failure of the principle in the case of Irish small

farmers; but we need not enter into that matter at present.

With regard to the production of butter, French dairy farmers all admit that the most scrupulous cleanliness is absolutely essential. The process followed in making the premier butter of France, known as Isigny butter, is as follows:—The sows are milked morning and evening, and in some cases three times a day, into jug-shaped vessels made of copper lined with tin, and holding about two gallons each. The milk is taken to the dairy, and is strained through a sieve lined with clean linen into earthenware buckets. These buckets are placed in a row in the milk-house, and the milk is then set for twelve hours. The cream skimmed after the first twelve hours is not mixed with what is taken off afterwards until immediately before churning, and in some instances butter of exceptional delicacy for Paris is made entirely from the twelve-hours cream. The quality of the butter is deteriorated when the milk stands longer than twelve hours; and although long standing increases the quantity, the price obtained

does not compensate for loss of quality.

The cream is churned twice or three times a week in a barrel The cream is churned twice or three times a week in a barrel churn. The churn has fixed dash-boards, which do not extend to the circumference of the churn. The dash-boards are perfectly plain laths, and the churn altogether is a model of simplicity and effectiveness. According to the size of the churn it is furnished with one or two large openings, which are open and shut by one of the usual contrivances employed in other barrel churns. There is also a vent peg placed in or near the head, and intended to be used as a ventilator if necessary, and a spigot placed in the bulge midway between the two large openings of a large churn, or opposite the large opening of a small one. This spigot plays an important part in the process of butter-making.

important part in the process of butter-making.

The churn is about half filled with cream at a temperature of about 57° Fahrenheit, and the best butter makers do not churn at a greater pace than from thirty to forty revolutions per minute, according to the season. As a rule, the butter comes in from twenty to thirty minutes, and the churner listens most attentively so as to detect in an instant the slightest alteration in the sound of the churning cream. An alteration being detected, or even suspected, the churn is at once stopped, in such a position that subjected, the dutin is at once stopped, in such a position that the spigot is about the level of the cream in the churn. The spigot is then carefully withdrawn, and the adherent matter minutely examined. If this is still cream the churning is renewed and the sound carefully attended to; but if, on the contrary, and the sound carefully attended to; but if, on the contrary, there are particles of butter on the spigot, no larger even than a pin's head, the churning proper is finished. A quarter of a turn of the handle now brings the spigot to its lowest point nearest the ground, and immediately beneath it is placed a sieve over a vessel to receive the buttermilk. The spigot being then slightly drawn out the buttermilk escapes and filters through the sieve, which retains even the smallest particles of butter which may be carried out by the buttermilk. When most of the buttermilk has thus been withdrawn from the churn, the small quantity of escaped butter is replaced in it, and fresh suring water is also put escaped butter is replaced in it, and fresh spring water is also put into the churn until it is half full. Three or four turns are then given, and the mixture of water and buttermilk is again with-drawn as before. This process is repeated often seven or eight times, until the water which comes out of the churn is as bright and clear as it was when put into it. At the end of the process the butter may be seen floating as one mass in a small lake of clear water. When removed from the churn by means of large wooden spoons, the butter requires no more working than is suffiwooden spoons, the butter requires no more working than is sum-cient to consolidate it and express the particles of clear water from its interstices. The butter thus made goes direct to Paris, where the farmer receives for it as much as 2s. and upwards per English pound, according to the season. None of this first-class butter comes to England, and it is actually second-rate French butter, made with less care and skill, which beats the best English and the best Irish butter in the London market. This is a significant the best Irish butter in the London market. This is a significant and remarkable fact. Mr. Jenkins states as the result of careful inquiry, that, other things being equal, the quality of the butter

depends upon the earlier or later period at which the working in the churn is commenced. This is so far recognised that some French dairy farmers have their churns fitted with a glass window to enable the eye to see and thus assist the ears when the butter

first begins to be churned.

Certain operations required in the cure of butter prepared for exportation, such as kneading, working, and salting, are performed by the buyers who purchase the butter from the farmers. Machines by the buyers who purchase the butter from the larmers. Machine have been constructed to facilitate those operations, engraving of which are given by Mr. Jenkins. The best butter destined for exportation to England is not actually salted, but for the final working a strong solution of salt is used in place of pure water. Ordinary butter is salted by the admixture of 8 to 5 per cent of its weight of salt if for consumption in England. French butter of ordinary quality is excellent for immediate consumption, but it of ordinary quality is excellent for immediate consumption, but it will not keep very long without a large quantity of salt, from the battering it undergoes in the process of making up by the merchant. French butter is sent to the London market in kegs holding about 70 lbs. each, in crocks protected by an outside basket, and in boxe containing one dozen 2-lb. rolls. Extreme cleanliness and nestness are characteristic of all the methods, and they are further distinguished by the free and almost lavish use of clean linen lining.— (Irish Farmers' Gazette.)

THE POULTRY CLUB.

WE are requested to announce that a Committee Meeting of the Poultry Club will be held at the Crystal Palace Hotel on Monday 17th inst., at 5 P.M. The General Meeting will be held in the Palace on Tuesday 18th. As the Club are unable to obtain a suitable room in the Hotel, the Manager of the Crystal Palace has kindly placed the Opera Theatre at their disposal, but for the morning alone in consequence of which the arrangements for the kindly placed the Opera Theatre at their disposal, but for the morning alone, in consequence of which the arrangements for the Meeting have not been finally settled, but a notice of its time and place will be sent to every member. At the General Meeting Miss May Arnold will call attention to matters connected with the late contest of incubators at Hemel Hempstead. The Secretary will propose the addition of a new rule—"The Committee are employed to the secretary will be additionally with the secretary propose the addition of a new rule—"The Committee are en-powered to disqualify a show; and any member who after due notice of the fact exhibits a show so disqualified shall cease to be a member of the Club, unless the Committee see good reason to the contrary."

VARIETIES.

WE have received a notice to the effect that a meeting will be held at the Crystal Palace on Wednesday, November 19th at 2.80 P.M., with a view to the formation of a Turbit Club, and the discussion of a draft of rules and regulations for governing the same. The Honorary Secretary protem is the Rev. T. B. Combe Williams of Sela Villa, Upper Beeding, Hurstpierpoint. Among the prominent Turbit breeders who have promised to attend are Mesars, T. Coke Burnell, Charles A. Crafer, George Roper, and W. F. Lumley.

BIRMINGHAM CATTLE SHOW.—The entries of cattle are 18; sheep, 64; pigs, 52; corn, 29; roots, 176; potatoes, 188; poulty and Pigeons, 2866—total 8472. These figures show a considerable increase on late years, particularly in the cattle and root

THE Canterbury Show is advertised to be held on December 11th, 12th, and 18th. We observe that after having been thrown open the Show will again be confined to six counties as formerly. We are pleased to see this reaction, as we always favour local shows if their area be not too restricted.

— The Committee of the Shrewsbury Poultry Show, being unable to obtain the use of the Market Hall on December 17th and 18th, have postponed the Exhibition till further notice.

THE Mid-Surrey Show of poultry, Pigeons, and cage birds will be held at Kingston-on-Thames on December 18th, 19th, and 20th. The schedule is a good one. There are thirty classes for poultry, twenty-two for Pigeons, and eleven for cage birds, besides local classes for poultry and Pigeons.

POTATOES.—There is no doubt that this season the produce of our own growth of potatoes is turning out a most lamentable one. Happing, however, English money, notwithstanding depresone. Happily, however, English money, notwithstanding depression in trade, can replace from foreign countries almost an unlimited quantity at moderate prices. Very large supplies have come and are coming forward from German ports, and what perhaps is still more satisfactory is that the quality is very good. Our Cauadian provinces are likewise prepared to ship to almost any extent, but it is a question whether they can compete with the German in price; that they can do so at a free-on-board price there is no doubt, but with such a heavy and low-priced article as the potato freight is a serious consideration. It is satisfactory to find that some of the principal large houses in the foreign min the potato freight is a serious consideration. It is satisfactory to find that some of the principal large houses in the foreign full trade are taking to them, and call the grocer's attention to the sale of an article of such large consumption. For doing so they are to be commended. It will be satisfactory to the general public in this country to know that, with literally no crop here, yet there

is no failure abroad, and large crops there mean moderate and low prices hera.—(The Grocer.)

STANDS AND COVERS FOR HIVES.

WE are unacquainted with any advantage that aspect may give to an apiary, for we have failed to notice any difference of re from hives facing south, west, north, and east. We have found hives on the north side of a high wall where they were always shaded do as well as those exposed to the sun all day. The position of an apiary so far as aspect goes is in our opinion of no moment whatever. A spot well sheltered from winds at some distance from large sheets of water, and free from noisome smells, is an eligible position for bee stands or bee houses. A sheltered is an eligible position for bee stands or bee houses. A sheltered spot for the apiary is an advantage to bees both in winter and summer. In hatching brood they dislike winds, and often close their doors against their chilling influence. Young bees in making their first attempt to fly are easily chilled and brought to the ground. Bees at work in the fields dislike winds, and prefer to go to and from the fields by roundabout routes rather than lose time and risk their lives in battling with the wind. In windy places bees with heavy loses have some difficulty in entering their hives, and in such places both hives and covers need to be well fastened. and in such places both hives and covers need to be well fastened down to prevent their being upset and displaced during gales and gusts of wind.

I have to confess that my prejudice against bee houses becomes less and less every severe winter, for in them hives are more easily protected from cold and rain than they are on common stands. In this cold and changeable climate hives out of doors cannot be too well protected from cold and damp. Bee houses proper—i.e., houses for hives, are in our practice and experience inconvenient in summer when artificial swarming and other manipulating pro-cesses are oft resorted to—inconvenient, too, for the examination

of hives.

Common stands are made by driving three posts into the ground for every hive, the front a little lower than the other two, so that the rain which falls on the flight boards runs outwards; and here I may state that it is well to have the edges of all floor-boards beveiled all round, fronts, sides, and backs, so that all rain and condensed moisture that may touch them will run off.

The height of stands or the distance hives should be off the The height of stands or the distance hives should be off the ground is not a question of great moment. Some bee-keepers perch them high and some perch them low. We think 8 inches above the level of the ground is quite high enough in summer, and perhaps rather too low in winter. As already indicated floor-boards should be kept dry, especially in winter, for if a severe frost come and find them full of moisture they become too cold the standard and complications. frost come and find them full of moisture they become too cold for the bees. Care in keeping hives dry and cozy in winter is, in our opinion, pretty good evidence that the bee-master practically knows what he is about; evidence, too, of past and future success. About four weeks ago I went down to Scotland to see if the thirty hives I left there in July had food enough for the winter. They all required feeding, and as my time was limited I obtained 2½ cwt. of sugar, boiled it into good syrup, which was all given to them in a few days. Each hive received 8 lbs. daily. We used no feeding vessels, simply because we had none. The syrup was poured over the combs from a small watercan without a rose. Throughout the past summer and autumn our bees had above 1200 lbs. of syrup thus poured amongst their combs. When bees 1200 lbs. of syrup thus poured amongst their combs. When bees are rapidly fed in autumn the heat and moisture of hives increase, and their boards become black with moisture absorbed. At the close of the autumn feeding the bee-keepers of the neighbourhood where my hives are remove the wet boards and put dry ones in where my nives are remove the wet boards and put dry ones in their places. This I could not do, for I had no boards in Scotland save those on which the hives are standing; hence our hives were fastened down ou damp boards solely from inconvenience, being two hundred miles from home. We failed to carry into practice the common custom of the local bee-keepers. Common stands should be from 4 to 6 feet asunder, so that room enough is left between the hives for covering and examining them. Where few hives are kept and space is of no consideration we would advise them be set further apart.

Covers for hives are necessary at all seasons to give them protection from rain, cold, and sunshine. Good covers cost something, and hence anything handy that will answer at all is often used. Indeed in large apiaries, at least in my own, many things used. Indeed in large aplaries, at least in my own, many things are used for covers that give but scant protection and cannot be recommended. What kind of covers should be used? Waterproof ones: I mean such as will shed off outside both hives and boards all the rain and snow that may fall on them, and at the same time permit all the internal moisture of the hives to pass off same time permit all the internal moisture of the hives to pass off and escape. Oiled cloth, waterproof cloth, tarpaulin, and roofing felt do not let the moisture of hives pass through them, and therefore should not be used as undercovers next to the hives. If used next to the hives they would catch and condense the moisture that escapes from the hives and keep their crowns constantly damp, and it is well known that damp hives are a fruitful source of mouldy combs, and the danger is greater if the crowns

Now let me mention an instance of my forgetfulness. The last

day of my short visit to my bees in Scotland arrived. Almost all the hives were insufficiently covered. I went into an iron-monger's shop and bought some roofing felt at 4½d. a yard, and some better at 7d. a yard. The best kind I used extensively for outside covers for hives—old carpets, old cocca-nut matting, and old clothes for undercovers. Well, I made the felt bought in Scotland go as far as it could fill I come to the lest four hives to old clothes for undercovers. Well, I made the felt bought in Scotland go as far as it could till I came to the last four hives to be covered. About 4 or 5 yards of the best felt only was left. This was cut in four equal pieces, put over the crowns of the four hives, and tied down closely to their sides. In my hurry to have the work done the internal moisture of these four hives (and they are work done the internal moisture of these four hives (and they are very strong ones) was overlooked and neglected, and this fact so haunted me on my return to England that I wrote a letter to the person in whose garden the hives (with waterproof felt hats) are standing, asking him to raise the felt covers and put some hay or straw beneath them so that the moisture of the hives will escape; also to pierce some holes through the crowns of the covers. Whether he has done this or not I cannot tell, for I have not heard from Scotland since I left it last time. If the hives remain as I left them without ventilating materials under the felt covers as I left them without ventilating materials under the felt covers their crowns, I venture to assert, are damp with condensed moisture, and many of the combs will mould and rot.

and many of the combs will mound and rot.

In concluding these remarks shall I be permitted to submit one consideration? If moisture is hurtful on the outside of hives what must it be on the inner surfaces? If the materials of covers should be porous, what should the materials of hives be? If external ventilation is desirable, surely internal ventilation is necessary. This is not the first time that this question has been necessary. This is not the first time that this question has been submitted for the consideration of the intelligent bee-keepers of Great Britain, neither will it be the last time; for amongst the honest active men of the bar-frame school, ever advancing onwards, this important question will with increasing power force itself into notice. In every school of apiculture there is a door left open for improvement.—A. Pettigrew.

ARTIFICIAL POLLEN.

MR. CHESHIRE'S discovery of a new method of giving artificial pollen is one of the most important that has been advanced of late postern is one of the most important that has been advanced of late years, and the thanks of the whole apiarian community are due to him for the promulgation of it. If I mistake not it has been published to the English world at a somewhat critical time, for—owing to the lateness of the season throughout the year, which owing to the lateness of the season throughout the year, which still prevails—we have had as yet no ivy harvest. Last year the ivy blossoms began about us to attract bees at, or soon after, Michaelmas. To-day (November 4th) I have observed my bees carrying ivy pollen for the first time. If cold or wet weather should now set in for any continuance no pollen will have been stored since the middle of September. At present it is mild, and if open warm weather should prevail the ivy will yield a good deal of pollen, if not of honey, during the next fortnight or three weeks. But if not, let all earnest bee-keepers "make a note" of Mr. Cheshire's discovery and act upon it, especially in the early apring. in the early spring.

Very interesting, too, is his discovery of the fact, as to which there seems no reasonable doubt, that full-grown bees eat pollen, and that probably it is an essential item of their daily food. This will help to account for the vast quantities of it which are found stored up in all strong hives in autumn time, and for the very small quantity which is found to survive till spring. The quantity small quantity which is found to survive till spring. The quantity of brood reared during the winter months do not account for this. Some have ridiculed the idea of helping bees with a supply of pollen artificially, on the ground of the useless accumulation of it in hives. The enormous quantity stored up has not been a single ounce too much. The bees know best what they are about, and store in proportion to their numbers and probable requirements.—B. & W.

THE EFFECT OF FOUL BROOD ON HIVE POPULATION.

I HAVE been asked to state my opinion as to whether external apparent prosperity and strength of population is conclusive evidence of the absence of foul brood. I can only reply, Certainly not, and that the strongest hives of the apiary are the most likely not, and that the strongest hives of the apiary are the most likely to be attacked, for they have a larger breadth of grubs to give a nidus for the intruding micrococcus spores, and that just as the army of foragers increases the possible chances of contagion multiply. As well might be supposed that a city could not possess a large adult population if measles was found raging amongst its infants, or vice versa, state that the large numbers of adults was

proof that measles was unknown within it.

When foul brood breaks out it attacks grubs only, and for a When foul brood breaks out it attacks grubs only, and for a fortnight or so no actual difference is affected, but as it spreads population is reduced from two causes: Young bees do not all hatch out, some die prematurely, and the odour generally diffusing itself takes all heart and energy out of the workers; the broodnest gets by degrees choked, and the laying energy of the queen is thus repressed. The general effect is the gradual weakening of the colony it is true; but all can see that time is required for the destroyer to accomplish his purpose, and despite his sad work making havoc within, the bees may appear to be in the full swing of unhindered progress until the disease has a firm hold of every comb. No mistake could be more fatal than to conclude that all suspicion of foul brood is to be disregarded, and nothing done of a remedial nature because, forsooth, the population is strong.

Making a visit to a Hertfordshire village a few days since I found one apiary of skeps shockingly diseased, so much so that the sickening exhalation was painfully apparent as one passed in front of the hives. The owner remarked, "They have a queerish smell, they don't seem to do at all." How much need there is to teach on this matter !- F. CHESHIRE.

DO BEES KNOW THEIR KEEPER?

This question I have often heard answered in the affirmative. but as it was from very doubtful authorities I now put it to your readers with the hope it will be answered satisfactorily by some of them. I believe that it is a more important point than most people are aware of, and I wonder it has not been mentioned by some of your correspondents when replying to young beginners in bee culture, as much of the successful management of their in bee culture, as much of the successful management of their bees either depends on courage or giving the bees a reasonable time to become acquainted with them. Still, if it be true that bees know their master, how is it then that some people have bees for years and are afraid of them, and indeed in many cases have good cause for being afraid, yet at the same time an experienced bee-keeper can do whatever he likes with them with impunity? Where is the secret? I answer, In experience and courage, as seen in the cases of the keepers of wild animals. It is the courage and determination make them masters over a offerce is the courage and determination make them masters over so fierce a charge, while the timid would be hunted away. My employer a charge, while the timid would be nunted away. My employer tells me a story in confirmation of bees knowing their master. He says he heard of a bee-keeper who was very successful with his bees, and that they allowed him all kinds of freedoms with them; but after a while he was struck down with small pox, and when he went back to his bees, having become quite well, they would not recognise him, and he had to beat a speedy retreat.

FEEDING BEES THIS AUTUMN.

SEVERAL communications have reached me on this subject this autumn, as multitudes of bee-keepers have found out, when almost autumn, as multitudes of bee-keepers have found out, when almost too late, the utter poverty of their stocks. To all I have given the same answer, "Lose not a day while the mild weather lasts to supply what you can." A word of caution, however, is needed. Not only should the syrup now given be thicker than that given in spring and early autumn, but it should be fortified with a little rum or other spirit—enough to gently stimulate the bees and to act as a preventive against dysentery. A little salicylic acid, as recommended lately in this Journal, will improve the quality of this remedial addition to the bare sugar and water. this remedial addition to the bare sugar and water.

I examined several of my hives yesterday, which had remained quite inactive since I left off feeding them nearly two months ago. I was glad to find them well supplied and vigorous, so as to need hardly any assistance. All seemed in good health, with hives dry and clean. I therefore contented myself with giving five of them about a pound of food each, which will save their opening any sealed-up cells on this side the first frost. In recommending feeding on any large scale so late as this it must be understood that I do so only in cases where it is a necessity. Ido so only in cases where it is a necessity. As a rule it is certainly bad policy to stimulate bees unduly at this time of year, and a large quantity of syrup in open cells is apt to cause damp in the hive, owing to the unavoidable evaporation which accompanies it.—B. & W.

PRICKLY COMPREY V. RABBITS.—In reply to "E. C. O.," and in corroboration of the remarks of "A KITCHEN GARDENER" on the subject, Prickly Comfrey planted by me three years ago in a piece of ground overrun by rabbits has not been touched by them. -G. MILMAN Major-General.

OUR LETTER BOX.

DEVORSHIRE CREAM (A.B.).—The milk should stand twenty-four hours in the winter, half that time when the weather is very warm. The milk pan is then set on a heated stove, and should remain there until the milk is quite hot; but it must not boil, otherwise there will be a thick skin on the surface. When it is sufficiently done, the undulations on the surface look thick, and small rings appear. The time for scalding cream depends on the size of the pan and the heat of the fire, but the slower it is done the better. The pan should be placed in the dairy when the cream is sufficiently scalded, and skimmed the following day. The cream made in this way is so much esteemed that it is sent to the London markets in small square time, and always meets with a ready cale.

ROUGH GRASS IN PASTURE (H. B.).—Patches of coarse creeping grass will appear on various soils, and as nothing is said about the soil which is complained of we have no doubt that it is in consequence of the land being deficient in chalk or lime. It must, however, be noted that whenever the pasture is fed off by sheep as well as cattle that the sheep eat the finest and

sweetsst herbage, and bite so closely that it destroys the best grasses, and the coarser grass prevails in consequence. As, however, the case under consideration probably arises from the land being out of chalk the sour and coarse grasses prevail over all others. We think the best plan would be to pare the turf about 1½ inch deep next March and burn it, then give it about 20 tons per acre of fine-screened chalk, or about 11 tons of quicklimper acre spread over the surface, then drag-harrow the land and spread the abbee over the surface; then sow a mixture of grasses as follows, the quantity for an acre being as under—

Yellow suckling	1bs. 6 3	Alopecurus pratensis Pestuca duriuscula	îbs. 12 13
Permanent white or Dutch clover	3	Pos pratensis	19 13 14
Total heavy seeds	15	Total light seeds	60

After the grass seeds have been sown for a year or two 1½ cwt. of nitrate of soda should be mixed with 8 cwt. of bone phosphate per acre and applied.

soda should be mixed with Scwt. of bone phosphate per acre and applied.

FEEDING BEES (Busy).—You have been feeding your neighbours' bees as well as your own all this time, that is the only way of accounting for so small a quantity of honey being stored. Of course during a continued process of feeding there is a great stimulus given to the breeding of the queen, which in its turn induces a much greater consumption of food; but making all due allowance for this your bees ought to have stowed away at least from 10 to 15 fbs. The truth is you have been a public benefactor, for which your aplarian neighbours ought to vote you an address of thanks. Many a half-ruined stock within a radius of two miles has been largely indebted for existence to your kindness in providing an operation. of thanks. Many a half-ruined stock within a radius of two miles has been largely indebted for existence to your kindness in providing an operative banquet pro bono publico. This explains the "extreme liveliness" of the bees and their being "out in hundreds every fine day." We would advise you to make a shallow box closed all round save at the top, where there should be alargehole; over this place your hive. Let the box have a door or slide at the beck, by which you may introduce your "troughs." Feed at night in still warn weather, dosing the entrance of the hive except a very small hole big enough for a couple of bees to pass out at a time. Feed till your stock is left, heavier than it is at present. It would be advisable to let the hole of the box he near to the side of the hive with an opportunity for the bees to pass up and down continuously without flying, otherwise you may lose many bees in the box owing to their getting chilled while trying to return to the hive. For this reason a round box would be better for a common skep, the diameter of which should be the same.

DESCRIPTION OF HIVE (E. W. E.).—Mr. Hooker's hive will be illustrated and described shortly. We intend giving during the winter a series of hints upon hive construction, embracing the chief improvements that have made their appearance at the shows during the past season.

REMARKS.

Cool, bright, very fine day, overcast only for short time at noon;

Cool, origin, very nile day, overcast only for more time as soon, starlight evening.

Fine dry day, overcast at intervals; fine solar halo during the greater part of the foremone.

Very fine and bright till 4.30 P.M., solar halo 2.46 P.M., misty at 5 P.M.,

very time and oright till 4.30 p.M., solar halo 3.40 p.M., misty 25 p.M., very dense fog 9 to 12 p.M.;

8th.—Poggy and dull all day; clear evening.

9th.—Dull, overcast, dark day; fine evening.

10th.—Dull morning, slight rain 9 A.M. soon clearing, and much brighter in middle of day, drissile at 2 p.M.; dull damp afternoon and evening.

11th.—Dull morning, bright after 10 A.M.; sunshine from moon till 3 p.M.; cloudy in afternoon, rain 5.15 p.M. for short time, afterwards bright expellipht exemiler.

attright evening.

Another fine dry week, chiefly noticeable for the high and steady harometer, Nov. 5th to 8th inclusive, and for the fog on the night of the 7th.—
G. J. SYMONS.

COVENT GARDEN MARKET .- NOVEMBER 12.

THE supply of home Apples has been meagre during the week, imported goods completely ruling the market. There is no alteration in hothous fruit. Trade steady.

From observations taken near London during forty-three years, the average day temperature of the week is 48.0°; and its night temperature 34.0°.

AGAINST HARD PRUNING.

CCORDING to promise I return to the subject so well handled by "A NORTHERN GARDENER" in the Journal for July 31st, and if it appears that I am unpardonably late in doing so, I may say that there is still ample time for carrying out my recommendations, and also that such a formidable opponent, with huge army of other gardeners great and small behind him, is not to be attacked at a time when

one has little or no leisure for digesting the subject

in hand. Of course there are many points in the paper alluded to with which I thoroughly agree, and your correspondent will, I know, give me credit for admitting the soundness of his teaching as to the necessity for air and light, and its influence on the future well-being of the trees; the principal part of our disagreement will be about the manner of obtaining the desired ends. And here let me say that I invite no one to take part in this discussion who will not give each side credit for possessing ordinary common sense and a knowledge at least of the rudiments of vegetable physiology. We all like very well to get the best of an argument, but that is not the purpose for which the Journal Horticulture exists. Let us try to bear this in mind. and rather endeavour to grasp each other's meaning than catch at words which do not quite express what we would

"A NORTHERN GARDENER" recommends summer pruning, although it is but fair to say he does not go to extremes in this matter as many others do; on the other hand, I prune less and less every year. In short, he is for restriction and I for extension wherever there is a chance of carrying it out. Supposing we take the Apple as being at once the most important fruit and the fruit with which everybody is supposed to be acquainted. Your correspondent writes as if there were no such thing as an orchard of young trees in a bearing state which have not been subjected to summer pruning. I admit that such a thing is far too rare, but whose fault is it? Horticulturists have been writing them down with all their might as long as I can remember reading the papers, and now what have they to supply their places? Will bushes and pyramids have they to supply their places? Will bushes and pyramids do it? No. Whether you go in for beauty, quality, or productiveness, there is nothing that can at all compare with an orchard of young standard trees on the Crab stock. Have to wait a lifetime, would you? Again I say, Whose fault is it? Throw away your pruning knife, and many of the best varieties will produce a crop in half a dozen years such as none of your pigmies can possibly bring to perfection. If you wish the growth of a vigorous tree to be crowded prune it hard, and you will soon have three or four branches in the place of one; on the other hand, if you want it to produce fruit early of the best quality and largest quantity, and to continue to do so for a couple of generations with little or no expense or trouble, do not touch it with the knife. unless in rare cases for the sake of balancing the head of a young tree or cutting out a cross branch. In the latter asset the cutting must be supplemented by rubbing off any its branches will be so disposed that light can reach its very centre. Why, then, should we give preference to ill-placed shoots which may follow as a result of the cutting; pigmies which only bear fruit by the dozen to good-sized

but as I maintain there is generally more harm than good done by cutting such trees, the soundest general advice I can give is, Do not cut them at all. Plant healthy young standard trees on good meadow land sufficiently wide apart that they cannot touch each other in a century, stake them securely, protect their stems simply with a piece of wire netting twisted round them, and keep the grass fed down with sheep, or even with cows if you like to put a little more protection round the stems. Do not merely dig a square hole and push the roots in; but if the land is at all heavy take the turf off 11 inch thick and sufficiently wide that every important root may be spread out horizontally to its full length, then cover carefully, filling up every crevice with the fingers with about 2 inches of fine soil in a dryish state, such as may be found on the surface of any vegetable garden, lay the turf down again and beat as hard as possible. If the land is light and dry, then the trees may be put in a little deeper, but in every case the roots must be spread out flatways, and the stem must not be buried more than an inch deeper than it had been before. Do not dig for the sake of making the soil lay lighter, as all fruit trees prefer the soil to be as hard as a turnpike road, nor for the sake of mixing manure, as when that is necessary it is much better to apply it to the surface. November is the best time for planting. Young trees moved then scarcely receive any check, while those shifted late in spring often do not recover for several years. When the trees commence bearing an occasional dose of half-inch bones (not chemically prepared), say a quarter peck to a tree once in four years spread on the grass over their roots, will greatly assist them.

"A Northern Gardener" brings forward some evidence to prove that there is a better crop this year on trees which have been subjected to summer pruning than there is on those which have not been so treated; but I have taken some trouble to look into the matter, and find that I could bring forward instances to prove the very opposite; therefore we had better dismiss this part of it with a verdict of not proven, and say that varieties and local influences have something to do with it.

Your correspondent very truly says "there are thousands of so-called pyramid and bush-fruit trees at this moment into the centres of which the light can find no entrance, and leaves and spurs are in semi-darkness." No one can deny that this state of things exists even where we ought to expect to see something better, but we differ about the cause. My opponent says they are pruned too little; I say they have been pruned too much. Pruning affords only temporary relief, like cutting one's corn and still wearing the small shoe which caused it. If the foot had been allowed to expand in a natural manner the corn probably would not have come, but being there it demands the attention of a skilful chiropodist and a cessation of the evil which caused it. In like manner a naturally grown tree will generally acquire the beautiful form which Nature intended it should, and needs no surgical operation;

No. 973.—Vol. XXXVII., NEW SERIES.

NO. 1625.-VOL. LXII., OLD SERIES.

trees capable of bearing a sack? I know it is said by some that the quality is superior on the small pinched trees, but this I totally deny when both have fair treatment. I care not what the kind of fruit is, you invariably have the best quality while the tree which bears it is enlarging at a moderate rate. Let it be too gross or let it be crippled either by starvation, old age, or by having the fashionable process of horticultural millinery carried to the extreme, and you immediately lose quality.

Standard trees have an advantage too often overlooked in the matter of temperature. Being comparatively out of the reach of radiation they may escape the effects of a slight frost, which would prove fatal to their tender flowers were they nearer the ground; they also dry quicker, and are at times, therefore, less sensitive to frost if it should touch them.—

WILLIAM TAYLOR.

NOTES ON THE SPRING FLOWER GARDEN.

This portion of flower-garden decoration has risen rapidly and extensively of late years, and in our opinion spring-flowering plants are as beautiful, or more so, than a great many of the plants employed for summer decoration. This year will perhaps be the means of guiding some not to adhere so strictly to the formal system of bedding. We were glad to see some useful hints on perennial plants that stood out so boldly against the drenching rains, and under the most adverse circumstances produced their floral beauty. Many who delight in seeing plants massed together and producing a blaze of colour in summer will doubtless be slow in discarding them for the quiet colours produced amongst perennial plants; yet many good, useful, and striking flowers are amongst them which find no place in many well-kept gardens. We may safely conclude that hardy plants will keep the gardens and grounds gay for a much longer time than the tender summer occupants weeks at the most, and in unfavourable seasons end in disappointment.

In many places after the summer occupants have been removed the flower beds remain bare all winter, and in spring when early flowers produce a charm and enliven the woods the garden still has a naked and deserted appearance. We may safely say where the present system of flower gardening is carried out the beds present a miserable appearance for eight months out of the twelve, and two out of the remaining four only are they in their beauty in the most favourable of seasons. Daisies, white, red, and pink, are amongst the most seasons. Dasses, white, red, and pink, are amongst the most gay of spring-flowering plants, yet they are considered common by the majority because they are seen in nearly every cottage garden. They are easy to increase and grow, and it is wonderful how rapidly they multiply under the most unfavourable circumstances. Then there are the Aubricias with their small purple and lilac flowers. We consider A. graca the best, purple and lilac flowers. We consider A. greea the best, although the violet blue A. Campbelli and the purple A. Mooreans are both good; they are lovely dwarf plants, and produce their blooms in great profusion. They are easily raised from seed sown outside in April, and make good plants ready for planting in autumn. Again, what is better adapted for emplanting in autumn. Again, what is better adapted for employing with the above plants than Pansies and Violas? We need scarcely describe varieties, but V. cornuta Perfection flowers too late to be used with the above plants; while Blue Bell and Dickson's Golden Gem flower profusely. The Tory is a useful one, but we are inclined to prefer the Cliveden varieties, all of which are profuse bloomers and admirably adapted for the purpose. Myosotises are very useful plants, being well suited for the spring flower garden, comprising as they do both tall and dwarf-growing varieties, so that either can be employed according to the size of the other paring plants used. M dissisting in a company plants used. spring plants used. M. dissitiflora is very suitable for associating with the plants named both for its floriferous character and dwarf habit. Primroses and Polyanthuses are beautiful, the former presenting so many shades of colour; they are among the first flowers to open after a cold and dreary winter, yet a few are worth a place in the mixed border. Arabis albida and its variegated form are useful spring flowers, suitable for the mixed border, but by no means suitable to be employed with Daisies, Aubrietia, Pansies, &c. They bloom too early, and the Arabis would present a seedy appearance before those mentionedr each the height of their beauty.

Limnanthes alba, L. Douglasii, and L. grandiflora though late bloming, Wallflowers of different varieties, Alpine Auriculas, Almsum saxatile and its variegated form, and many others,

are all plants worth growing for the effect they produce in spring. Silene compacts is most desirable for spring beds, especially when it comes in in time to be employed with Daisies, &c.; but here it is a little too late for that purpose unless kept in pots in a cold frame during winter and planted out in early spring. The old but useful Cerastium tomentosum with its small white flowers is pretty in spring when associated with Myosotises and Pansies and other spring flowers. Bulbons plants add materially to the adornment of gardens in spring. Snowdrops and Crocuses though short-lived should not be passed nor despised, because they are two of anxiously looked for to gladden and remind us of the approach of spring. We have quantities here, especially of the former, planted by the sides of walks and springing from the midst of stones overgrown with moss, which wonderfully assist in showing to advantage their snowy flowers and arrest the attention of visitors when in flower; yet how slow are many in trying to make their gardens gay in spring! No better nor more appropriate place could be chosen for the lovely little Scillas and the beautiful Triteleia uniflora with its light flowers shaded with blue. This little gem is worth extensively growing for spring gardening. Scarcely need we stay to allude to the beauty and usefulness of Hyacinths, Tulips, and Narcissuses. It is well known they are amongst the most beautiful of flowers, and present when grown in quantity an admirable effect that few plants can equal.

The work of planting in the spring garden should be brought to a close as quickly as possible. It not unfrequently happens, where the beds are occupied with the summer bedders, that an attempt is made to keep them neat until frost cuts them off, and then the fall of the leaf where trees abound make a great amount of labour for a time, and the work in the spring garden is often unavoidably postponed; but be it remembered that those plants that are planted early and obtain hold of the ground before the winter sets in do much more satisfactorily in spring, and are net so liable to be lifted out of the soil and suffer by frost. Last winter was most severe on spring-flowering plants, and unsatisfactory results only were attained except by those who had their plants thoroughly established in early

autumn.

In carrying out designs in beds or borders with spring flowers it is well to avoid making the patterns too complicated. The simpler the design the better the effect, especially when the lines are marked out with Golden Feather. Few can form an adequate idea of the beauty and the fine effect produced by the combination of spring flowers when grown in quantity, and the aim of the flower gardener has been to arrange only those in the flower garden proper that bloom at the same time, so that no blanks are made and no plants looking seedy while others are only in their beauty. Those that produce flowers early and those that produce them late are much better adapted for the mixed border than for beds which should only contain plants that bloom about the same time, and last about the same time in beauty, and are arranged in harmony to produce the desired effect.—WILLIAM BARDNEY.

DIGGING, TRENCHING, AND CROPPING.

THE great difference in the management of farms and gardens lies mainly in the depth to which the soil is cultivated, and until the farmers are provided with efficient implements which will turn over the ground to a good depth at a cheap cost there is not much hope of farming being made profitable in face of the foreign competition which yearly increases. Gardeners will have the same competition to contend with by and by. The only chance of holding their own must lie in following intelligently the best modes of cultivation at present adopted. One of the surest modes of keeping the soil in s high state of fertility is cultivating it to a good depth on every occasion it may be required to turn it over. Ground that is to be permanently cropped should be turned up at least to the depth of 30 inches, not necessarily bringing the subsoil to the top; but the bottom of the trench can be dug up a spit deep, and dung or other fresh material dug in with very great advantage. The same mode of improving the general garden may

be proceeded with where it has been neglected.

We make a point of turning over every piece of ground that we can to the depth of from 18 to 30 inches every year, and really fertile soil has been much improved. Some portions, from the nature of the crops, are trenched every season; other portions remain for two or more years without being trenched,

but provided the ground is in thoroughly good condition that is of little consequence. In trenching I find it of great importance to break up all lumps or clods as they are turned in the portion left on the surface of the freshly turned ground being left rough. I have found that lumps of soil turned into trenches remain as lumps in many cases till the soil is trenched the succeeding year. In soils such as I have to do with, which require plenty of manure to keep them in a high state of fertility, I consider it of importance to work the manure well through the whole body of soil turned up.

Though our land requires a larger quantity of manure to keep it in a high tone than those having soils naturally fertile, at the same time our supply of manure is limited. For instance, a quarter of the garden at present occupied with growing Broccoli and Brussels Sprouts, with rows of late Peas at wide intervals, was occupied with Winter Spinach, which was cleared off and the other crops planted without any preparation. The Spinach again was sown after Potatoes and Peas. The Potatoes were preceded by Savoys, for which the ground was trenched, so that the amount of labour required when ground is in good heart is not so extraordinary. These Broccoli and Brussels Sprouts will be succeeded by Celery for two seasons intercropped with Peas, Lettuces, Turnips, and Endive. If the soil is considered too poor to carry a crop a surfacing of decayed manure at this season is beneficial. In digging ground it is of importance to have a good large opening to allow of the work being cleanly and effectively proceeded with. It is well to bear in mind that ground well worked at this season is very beneficial to the crops during the heat of summer.—

R. P. BROTHERSTON.

PEARS OR PEACHES.

The past season has shown pretty conclusively the desirability of substituting Pears for Peaches on the walls of many gardens even as far south as London. In exceptionally favourable situations outdoor Peaches may produce good fruit once in two or three years, but I doubt whether there are many gardens north of London where a really good crop is obtained annually without the aid of glass. My own experience in Essex is entirely against outdoor cultivation of Peaches. When I first took my garden in hand about 160 feet of south wall was covered with scraggy old Peach and Nectarine trees, the produce of which was chiefly remarkable for the stones being the largest part of the fruit. I removed the old trees, renewed the borders, and planted a selection of the best varieties, and after some years' constant attention covered the walls with well-trained young trees; but it was an incessant fight against green fly, blister, and mildew, with the utmost uncertainty of obtaining a crop. With a tithe of the labour, half the space under glass would produce more than double the quantity of superior fruit, and the first expense of the glass covering would not equal the cost of a few years' labour in keeping the outdoor trees clean.

Pears on walls give the least possible trouble; if properly trained they require very little attention, and by planting the best varieties only, fruit will be obtained very superior to what is generally met with, and much better than ordinary Peaches. The trees should be on Quince stocks, and if space is limited may be planted as diagonal cordons 21 inches apart, or trained in a variety of suitable ways according to taste. Pears require special attention as soon as the fruit is ripe enough to be gathered; and the early varieties should be gathered at intervals of a week in order to prolong the supply, looking over each tree and picking half of the most forward fruit, and a week later the remainder.

The early varieties worth a place on the wall are Beurré de l'Assomption, Williams' Bon Chrêtien, Souvenir du Congrès, and Madame Treyve, all large fruit of first-rate quality.

For midseason supply the great difficulty is to make a

For midseason supply the great difficulty is to make a selection from so many that are good, but none of the following could well be left out:—Beurré Superfin, Louise Bonne of Jersey, Duchesse d'Angoulème, Pitmaston Duchess, Thompson's, General Todtleben, and Doyenne du Comice. I have left out Marie Louise, as it is a shy bearer, and ripening at the same time as Thompson's is in on way equal to it.

same time as Thompson's is in on way equal to it.

For late supply from Christmas onwards Winter Nelis stands first, and is followed by Nouvelle Fulvie, Joséphine de Malines, and Bergamotte Esperen. Olivier de Serres is also

This list may appear too short to some of your readers, but I | fortunately subject to die off branch after branch, therefore we have purposely named only such varieties as may be generally | recommend the Peach and Hemskirk, both excellent. As

relied on. It must be borne in mind that with midseason, and especially late Pears, everything depends on proper keeping and ripening. They must be kept cool, but not too dry, a good wine cellar being the best place, and matured in heat, the moist warmth of a hothouse answering better than a dry cupboard. Perhaps some of your readers will favour us with further information on this point, as it is a most interesting one.—Essex.

HOYA BELLA.

This is commonly and appropriately called the Honey Plant or Wax Flower. The plant is of a semi-scandent, compact, free-flowering habit, producing its waxy white flowers with rosy centres from midsummer till late in the autumn. Small well-grown plants when in flower are very suitable for the dinner table or drawing-room; it is also very effective when grown in wire baskets suspended from the roof of the stove. Plants when large and properly trained to small neat stakes are good for exhibition. Cuttings taken of the half-ripened wood strike freely in a moist gentle bottom heat; when well rooted they should be potted-off singly into 2½ or 3-inch pots, employing a compost of equal parts turfy peat and loam, a little sharp sand, and sufficient small pieces of charcoal to keep the soil open. After potting the plants must be kept close and shaded from bright sunshine for a few days, afterwards stake and tie them into shape, and gradually inure the plants to light airy positions near theglass, syringing them on fine afternoons while making their growth, and keeping up a moist atmosphere. The next shift may be into such size pots as may be deemed necessary, as large plants can be grown in comparatively small pots. Care must be taken at all times not to give them too large a shift, as if overpotted they will turn yellow in the foliage. The plants must not on any occasion be allowed to suffer at the roots by want of water; supplying them once or twice a week with a weak solution of soot water will greatly improve their condition.—James Skyrme.

SEASONABLE NOTES-PLANTING FRUIT TREES.

TRENCHING, border-making, tree planting, &c., will render the next month an exceedingly busy one to fruit-growers. Where planting young trees is contemplated it is time to send in orders to nurserymen to insure an early delivery. Amateurs and others not acquainted with the numerous varieties now enumerated in most catalogues may be in doubt which to select. For the guidance of such we subjoin a short descriptive list of those we have proved to be good reliable varieties and adapted for most soils and situations. Deep trenching should precede the planting of all fruit trees with a liberal admixture of good maiden loam, top-dressing with well-decomposed manure.

posed manure.

We will commence our list with Apples, taking them as they come into use. The Keswick Codlin is one of the very best for culinary purposes, and seldom fails in producing a crop. Lord Suffield is a general favourite, and is deserving a place in every garden. For dessert none surpasses Kerry Pippin, Ribston Pippin, and Cox's Orange Pippin succeeds them in the order named; they are first-class in appearance and quality, and good keepers. To these should be added Blenheim Pippin and Waltham Abbey Seedling, which will last in use till the end of February, when the following will continue the supply as long as Apples can be kept. Cockle's Pippin, Dutch Mignonne, Court-Pendu-Plat, and Sturmer Pippin for dessert. For cooking purposes the Herefordshire Pearmain, Dumelow's Seedling, Alfriston, and Northern Greening. Among Pears the following may be entirely depended upon:—The best for early ripening are Williams' Bon Chrètien, Beurré Giffard, Beurré d'Amanlis, Doyenné du Comice, Beurré Superfin, Marie Louise, Louise Bonne, and Beurré Bachelier, which will carry the supply up to near Christmas, when Bergamotte Esperen, Glou Morceau, and Joséphine de Malines are the only real good varieties for late use known to us. The best Peaches are Early Louise for the first, Royal George, Grosse Mignonne, Dr. Hogg, Alexandra, Bellegarde, Barrington, and Walburton Admirable. Among Nectarines Lord Napier is a most valuable variety, very early; size very large, of fine colour and most exquisite flavour. Stanwick Elruge succeeds this, and of late varieties Pitmaston Orange and Humboldt are the best. Among Apricots none equal Moorpark in quality, but trees of this variety are unfortunately subject to die off branch after branch, therefore we recommend the Peach and Hemskirk, both excellent.

regards dessert Plums, Green Gage stands first, then come Kirke's, Jefferson, Coe's Golden Drop, Reine Claude de Bavay, and Reine Claude Violette: and for cooking purposes Prince of Wales, Prince Engelbert, Victoria, and Pond's Seedling. The best Cherries for dessert purposes are Black Eagle, Early Black Knight's and Tartarian, and of white kinds Governor Wood, and Elton; while for cooking none surpass the May Duke and Morello. Bush fruit not being so important it is hardly worth while occupying space to give a list.

Excepting with the more experienced cultivators a practice on receiving trees from the nurseries is to reduce the tops considerably. This is a common practice with some growers, but a greater mistake could not possibly be perpetrated. more branches and foliage a tree is allowed to carry the more roots will it make, and the less chance is there of its producing strong gross shoots; but on the other hand cut it back, and its growth and strength are concentrated in a few buds that start away most strongly in the spring. Healthy trees such as are generally supplied, if planted early will always afford plenty of shoots to choose from without having their tops reduced. We never shorten under any circumstances unless it be the extreme tips not quite ripe or any bruised through packing or carriage, but plant with the branches almost entire and properly laid in and trained. By this treatment they cover more than double the space the first year than they otherwise would and bear in less than half the time, and we are sure that those who may feel disposed to give this system a trial will never resort to the old practice again .- JOHN LLOYD JONES, The Mount, Congleton.

CHATSWORTH IN OCTOBER.

By whatever route Chatsworth is approached grand scenery surrounds the visitor. If we take the track by which thousands travel—the Midland Railway to Rowsley station, we have only to sit still and admire an apparently passing panorama as diversified as it is beautiful. Now high aloft we look down on the tree tops, and into deep verdant dales and glassy streams; anon we are in a cavernous cutting with rocky sides, down which the water trickles and Ferns luxuriate; and again we are on a steep declivity—looking upwards on the one side to the bold receding hills, and downwards on the other on far-reaching pastoral plains. Such is the picturesque railway route so familiar to many travelling from London to Manchester and Liverpool. From Rowsley a pleasant drive or walk of four miles leads to the Palace of the Peak. Other routes with "grand surroundings" are by coach from Chesterfield or Sheffield. From the last-named town there are two courses, the longer, about fourteen miles, by Froggatt edge being the most varied in its scenery. On a summer or fine autumn day no finer drive can be anticipated than that across the lofty Derbyshire hills. Froggatt edge appears an abrupt and rugged termination of the range, and the riven weather-worn rocks rise in grotesque weird forms—an example of the grand architecture of Nature which dwarfs the works of man into comparative insignificance. From the rocky heights vast boulders have been hurled with extraordinary force, and for ages have been embedded in the hillside, presenting a scene of grand disorder. The effect of the great disruption is enhanced by contrast with the splendid valley immediately below, where repose dwells and the Derwent pursues its steady serpentine course. roads referred to conduct to the pleasant village of Baslow, to which thousands of tourists wend their way during the summer, where they find ample and excellent accommodation for long or short sojourns, and have ready access to the ducal park, which is close on the confines of the village.

To all, the grandeur and surroundings of the mansion are highly imposing—the woody heights, the green valleys, the water scenes. The pleasure grounds in many respects are unique. The grand Emperor fountain forcing the water 296 feet high; and the lesser satellites enveloped in masses of silvery spray, when viewed with a slanting sunlight and against a deep rich background of foliage, command general admiration. The cascades; the Weeping Willow, a strange startling toy; the arched rockery barred by a gate of stone—a solid block of many tons, but so carefully poised on its central pivot that a child can turn it—these and other features are the chief points of interest to the mere sightseer, but not to the gardener. Chatsworth unquestionably is a grand place, not so boldly imposing as some other historical homes of our old nobility; here the artificial preponderates, and there is even something approaching the incongruous where the majestic fountain rises

from a reservoir in miniature. The novel is certainly blended with the beautiful, and the effect is in a measure startling. But for the gardener to see and be satisfied he must have access to the kitchen garden, to which the public are not admitted except by special order. He must not expect to see anything outwardly imposing there, but he may expect good practice, to see much work well done, to see range after range of glass turned to the best account in producing fruit, flowers, and vegetables of the first quality and in prodigious quantity; to see every inch of space devoted to an useful purpose—no waste, no guesswork, but to see order prevail and a masterly system pursued; in a word he may expect to see first-class gardening, and he will not be disappointed.

With conveniences for every crop, and special houses for every purpose—where the resources are great and the demands limited—no shifting, moving, and scheming—gardening is comparatively easy; but this is not the gardening of Chatsworth. True, the means provided are great, but the wants of a great establishment tax them to the utmost, and it is only by much thought on the part of the chief, judicious planning, a complete mastery of every detail—an instinctive mode of making the best of everything, a quick perception of wants ahead and clear prompt action to meet them, that the gardens can be kept in their present thoroughly satisfactory state and a full supply of the best produce maintained at the time it is

We entered the gardens by Mr. Speed's residence, such an one that not many gardeners are provided with, and after proving its hospitality had a rapid "run round." Adjoining the house is a venerable structure, not imposing certainly, but very useful. In this house the original of Rhododendron Gibsoni is planted out, a large healthy shrub or tree. Rhododendrons, huge Azaleas, and various other plants are similarly established, and yield in due season a plenitude of valuable cut flowers. From the roof depended the old Fuchsia corallins in rich elegant masses, from which armfuls of bright and graceful sprays might be cut if needed. The old house is doomed, but it cannot but be parted with reluctantly, for it shelters many an old valuable specimen, and is in many ways serviceable. Near it is the house devoted to the Amherstia nobilis, from which Mr. Speed has established a young plant. Arranged round the stem of the tree was a bright group of fine-foliaged plants, and it was striking to observe how well such plants as Crotons had coloured in the heavy shade: this was due, no doubt, to the great heat required by the Amberstia. Some of the newer Crotons, notably Lord Derby, were in splendid condition. Contiguous is the Victoria house with its large circular tank for the accommodation of the royal aquatic. Here we find the first instance of scheming. The family being away ornamentation was made subservient to utility, and round the house were arranged hundreds of plants in preparation for winter, such as Cinerarias, Primulas, Solanums, and many others that it is not needful to mention. The aquatics are doubtless now removed, the tank dried and filled with The plants were outside in readiness Chrysanthemums. plants not formally trained but naturally grown; large sturdy bushes in such exuberant health that the question could not be

at Chatsworth.

We pass on, glancing at a trio of houses for Vines in pots, one house accommodating during the summer a sufficient number, which when fruiting occupy the remaining structures, these in the meantime being devoted to other useful purposes; they were then filled with pots of Dwarf Kidney Beans, which would yield a valuable crop, to be followed by Grapes. The Vines had made medium canes, hard as oak, and with bold eyes; in fine condition for fruiting. We now reach the long ranges; there are nine or ten of them, not far short of 100 yards long each. In the first ridge-and-furrow house ever constructed the old Vines are in grand health. They were waning once, but, as has been told by Mr. Pettigrew, lime cured them. By years of manuring, the borders, though rich, were inert. Heavy applications of lime liberated the nutritive gases, which the Vines appropriated, and resumed their vigour, and now produce Grapes of the first quality. They were maturing their wood well, the foliage hanging well and assuming bright autumnal tints—precursors of future crops. The early Vines were ready for pruning; starting, for ensuring a long rest, is

suppressed. What have you been giving them? "Soot, nothing but soot," was the reply. That was the stimulant, and it is

certain that no other could have answered the purpose better.

Probably at the present time few finer displays of Chrysanthe-

mums are to be seen in the kingdom than in the Victoria house

deferred as long as possible, and then the time is made up by extra heat. In this work, early Grape-growing, the ordinary practice of starting with a low temperature, producing a slow and sometimes irregular break, is reversed. The Vines are started at once with a temperature of 80° for a quick break and regular, then the temperature is gradually reduced to the point required for ensuring healthy growth. This mode is found to give the best results, otherwise it would not be continued. Other ranges of Vines in full bearing presented a fine appearance, the crops being excellent and the berries fine. Black Hamburgh is the favourite Grape at Chatsworth, and is had in use as early and as late as possible. Muscats are also extensively and admirably grown. The garden being low—that is, in a depression between the hills, and the rainfall considerable—the outside Vine borders are raised above the general level of the garden, and the condition of the Vines prove the practice sound.

The Peach ranges are extensive, and the trees are in superior condition. The soil appears naturally suited for Peach trees, for one of the original trees, which is quite healthy, has a stem apparently about 2 feet in circumference. Younger trees are being constantly lifted and replanted to insure abundance of fibrous roots necessary for bearing crops of fine fruit. Figs are grown largely, and it may be said liberally, for there is no root-restriction nor no pruning. The trees are planted in good soil, and the house being very large they have space to extend. The trellis is about 3 feet from the glass, and the branches are loosely secured to it, and fine crops of very large fruit are produced. Melons are extensively grown, and just when the crops in the houses are over Tomatoes are well established in large pots for taking their places. The Tomatoes are grown on single stems trained obliquely on the walls and trellises, and bear heavily, maintaining a full supply of ripe fruit throughout the winter. A seedling Tomato raised from Cri-terion, but not at all like it, had fruit 41 inches in diameter and very firm; it is bright scarlet in colour and very slightly ribbed. Cucumbers are also grown in houses. At the back of one house were a large number of seedling Poinsettias, strong plants for flowering this season. They were the result of a cross between P. pulcherrima major and P. alba, and some interest is being manifested as to the way in which they will "turn out." There are apparent differences in the growth and foliage of many of the seedlings. It is a little singular that in another nobleman's garden the same cross has been effected, and the plants will flower this year for the first time. Some of Mr. Speed's seedling Dipladenias also merit notice. Egerton (amabilis × Brearleyana) has large, stout, well-formed flowers, pale peach or hawthorn pink—a delicate and lovely colour. The foliage is very fine and ribbed, and the plant is a strong grower. Thomas Speed has flowers of a deep rose and having a pale white border. The trusses are very large, some having ten expanded flowers. Pines are grown in pots plunged in brick pits—a superior sturdy healthy stock. Hundreds of Black Jamaica are grown for affording fruit throughout the winter onwards till June; that variety and Queen being "grown to eat; Charlotte Rothschild and Smooth Cayenne to look at." Successions are also in the same dwarf healthy state. Strawberries are forced by thousands, the pots meanthy state. Strawbernes are forced by thousands, the pots small and crowns large. James Veitch is a great favourite of Mr. Speed, producing fine crops of large fruit, and Sir Harry is also esteemed for forcing purposes. The soil of the garden is deep and good, and first-class vegetables are grown; but the climate is moist and cold, and this year Scarlet Runners were only commencing bearing in October, and the rows had to be covered with woollen netting to preserve them from the frost, which had already killed the Vegetable Marrows. Of fruits such as the Pear and Apple, crops, owing to the unpropitious climate, can never be relied on.

In the pleasure grounds, near the mansion, which is some distance from the kitchen garden, are some span-roofed houses, plain and unpretentious in appearance, but filled with splendid plants. In one of the orchard houses Yandas are grand, to be seen once and remembered for a lifetime, the finest plants probably in the kingdom. Coologynes are splendid masses; the Chatsworth and Trentham varieties with the well-known species yielding a valuable supply of flowers over a long period. Sarracenias are admirably grown, and especially noticeable is a remarkable example of S. flava maculata, of great size, and a smaller yet one of the finest specimens to be seen of S. Mooreana. Dendrobes were in superb condition, large and with excellent growths; and the pans of Indian Crocuses were

startling by their brilliancy. The effect of five hundred flowers in a mass of Pleione lagenaria may be imagined but cannot be adequately described; many of the corms were producing three and four flowers, and a few even five. In the decorative plant house the curious Ataccia cristata was flowering freely, the plant being in admirable condition; but the Heath house was the most attractive, not with Heaths, but with the grand terrestrial Orchid Disa grandiflora. This plant, so "miffy" in many places, is clearly at home here. The house contains a tank, and round the sides and over this tank the plants are grown; they were quite gorgeous and were seeding freely. In another house the Amaryllises were a "sight;" A. aulica and hybrids had enormous bulbs and foliage, several of the pots producing half a dozen heads of flowers. Some of Mr. Speed's seedling Amaryllises have received high honours, and the race is evidently a valuable one.

A long corridor contiguous to the mansion was attractive by the fine wall and climbing plants. Camellia reticulata is a remarkable specimen, and a pod of seed was ripening, the flower having been crossed with a white variety. On the same wall Rhododendron Edgworthii has produced a pink flower, the seedpod of which was swelling. The old Fuchsias in this

corridor produced a fine effect.

We cross the lawn to the grand conservatory—glancing expassant at two royal Oaks, the one planted by Her Majesty some years ago, the other recently by the Prince of Wales, the latter tree being a seedling from the former—and, passing through a wilderness of Ferns, reach the noble building. The Palms and other remarkable permanent specimens are in superior condition, and a side stage contains a fine collection of Epiphyllums and Cactuses. Many seedlings of the former plants have been raised and were about to flower, and many Cactuses have been intercrossed, so that something new may be expected by-and-by. It is not necessary to refer particularly to the Palms, &c., in the borders, nor to the fine baskets of Ferns overhead, nor to the Musa avenue, but an Orchid demands notice—a fine plant of Renanthera coccinea growing up a birch pole, which has produced sixteen large spikes of flowers, the remnants of which remain on the plant. Last winter the temperature of this great house, well as it is heated, often fell to 40°. Near the conservatory are some handsome specimens of Fisher's Golden Irish Yew; and beds of the fine old Lobelia cardinalis, with a groundwork of Dactylis glomerats variegata, were both brilliant and chaste. Chatsworth is undoubtedly a grand place, but the best feature of it is the excellent practice of the skilful gardener Mr. Speed.—J. W.

SYRIAN GRAPE.

I SEND you a few berries of the Syrian Grape which were cut from a Vine trained on the back wall of one of our vineries. Both my employer (Mr. Jardine) and myself consider this variety when well ripened of better flavour than Lady Downe's Grape. The berries sent have been ripe for the last two months. On the same Vine from which the enclosed berries were taken we cut a bunch which weighed 8 ibs. Taking into consideration this having been grown on the back wall shows what may be done by giving this Grape a good position in front, and allowing it to carry only medium-sized bunches. I have tried it in this way, and have found it to improve both in flavour and size of berry, and all who have partaken of them grown in the manner described have been highly pleased with the flavour.—James Dickson, Arkleton.

[The Grapes are very fine; berries large, oval, and pale yellow, with a firm crackling flesh of good flavour—just as this Grape ought to be, and is when well grown and ripened.—EDS.]

A TRIO OF BEAUTIES.

AT page 316, in notice to correspondents, something is said about Campanula isophylla. I have a high opinion of this plant, having cultivated it for many years as a hardy border plant, and as a dwarf edging plant for flower garden and other purposes. It is useful for cultivation in pots in early spring for indoor work, and again in autumn, and with care a long succession of bloom may be obtained. It is quite hardy here, and is worthy of more extensive cultivation. My second beauty is also a Bellflower (Campanula turbinata), larger in every respect, but of dwarf and compact habit, its flowers being much deeper in colour. It is very effective as an edging border plant, useful for indoor work, and quite hardy; they are not particular as to soil. They thrive in ordinary

garden soil, and are easily increased by division at any time. My third beauty is Veronica syriaca, a charming plant, which grows only a few inches high, but is very attractive, its in-tensely blue and white flowers producing a charming effect. Being an annual it reproduces itself freely from seed, and by successional sowing a fine display may be kept up. It is also well adapted for pot culture. It requires a rich light soil in a moderately dry situation.—SPEEDWELL.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 18TH.

THE meeting on this occasion was an extremely interesting one. The great features of the gathering were the Primulas from Mr. Gilbert of Burghley, the collections of plants from Messrs. Veitch and Bull, the Abutilons and Primulas from the Society's garden and Bull, the Adutions and Frimulas from the society's garden at Chiswick, and the numerous excellent collections of vegetables staged in competition for Messrs. Suttons' prizes. Several fine collections of Grapes were also sent, especially those from Mr. Gilbert, Mr. Wood, and Mr. Bell, which are referred to below.

FRUIT COMMITTEE.—Henry Webb, Esq., in the chair. Messrs. Wood & Ingram of Huntingdon sent a seedling kitchen Apple of a bright showy colour and brisk flavour. It did not present

wood a Ingram of Huntingdon sent a seedling kitchen Apple of a bright showy colour and brisk flavour. It did not possess any special merit over other varieties in cultivation. Mr. Chester, The Gardens, Connington Castle, sent a seedling Apple called Bellamy's Fillbasket, a medium-sized, round, ribbed, pale yellow Apple, with a soft flesh and mild subacid flavour. It was not considered equal to others already in cultivation. He also sent three varieties of seedling Pears, but as they were all mixed when they varied the Compilter and the resident of the second of the seco they arrived the Committee could not distinguish one from the other. Mr. P. Grieve, The Gardens, Culford Hall, sent fine specimens of Lucy Grieve Pear, but the flavour was not equal to specimens of Lucy Grieve Fear, but the navour was not equal to those exhibited at former meetings in more favourable years. He also exhibited a seedling Apple which promises well, but the season is so unfavourable to the flavour of fruit that the Committee requested to see it another year. Mr. Wildsmith, gardener to Lord Eversley, Heckfield, exhibited a fine dish of Pitmaston Duchess, excellent in texture, but, like all Pears this season, rather deficient in flavour. The Committee gave a vote of the large for the large for the flavour of the committee gave a vote of the large for Duchess, excellent in texture, but, like all Pears this season, rather deficient in flavour. The Committee gave a vote of thanks for the exhibition. Mr. George Sage, The Gardens, Ashridge Park, Herts, sent a dish of Vicomtesse Hericart de Thury Strawberry, to which a letter of thanks was awarded; Mr. Wood, The Gardens, Leybourne Grange, Kant, eight baskets of Gros Colman Grapes as they are packed for market, each basket containing about 9 or 10 hs. weight; they were splendidly coloured, and the flavour was excellent. The Vines on which these were grown were grafted on Madresfield Court Vine, and it was interesting to observe the difference between the fruit thus produced and that which was grown on a Vine of the Gros Colman on its own roots. In the former the berries were quite black and the flesh firm and well flavoured; in the latter the berries were only partially coloured, and the texture of the flesh more loose and inferior in flavour. Mr. Wood exhibited the fruit as he packs it for market. It is put into ornamental baskets, and the bunches are secured round the sides by the base of the stalks so as to prevent them moving, and these ornamental baskets are again placed in hampers moving, and these ornamental baskets are again placed in hampers large enough to admit them easily. When they arrive at their destination the ornamental basket is merely lifted out and is

mr. Bell of Alnwick exhibited six handsome bunches of the Alnwick Seedling Grape; they had been ripe for some time and had become shrivelled. The exhibit was commended with a letter of thanks to the exhibitor. Mr. R. Gilbert, The Gardens, Burghley, sent three handsome bunches of Gros Colman Grapes; the berries were large and well coloured; the flesh was very firm, and the flavour very fine. A cultural commendation was awarded. and the flavour very fine. A cultural commendation was awarded. Mr. J. C. Mundell, The Gardens, Moor Park, Rickmansworth, sent two plants in fruit of the "Scotch Bonnet" Capsicum, which is the best of all the Capsicums. Mr. S. Ford, gardener to W. E. Hubbard, Esq., Leonardslee, Horsham, exhibited fifty dishes of Apples and Pears, which were rather small but otherwise good in custific.

Mesors. James Carter & Co. of Holborn sent a dish of Scotch Champion Potato which was cooked and proved excellent in flavour.

FLORAL COMMITTEE.-Dr. Denny in the chair. The chief collections arranged in the Committee room were the following, all of considerable merit. Messrs. James Veitch & Sons exhibited several new plants; a first-class certificate being awarded for several new plants; a brat-class certificate being awarded for Lælia Dayana superba, an extremely rich rurple variety. Cattleya farista superba and C. Mastersoniana, both beautiful hybrids, were passed. Stelia Bruckmulleri is a dwarf species with spikes of small brownish fringed flowers. Mr. W. Bull sent a large collection of rare plants, comprising many beautiful Orchids, Cycads, lection of rare plants, comprising many beautiful Orchids, Cycads, Palms, &c. The following were the most noticeable:—Trichosma suavis, bearing spikes of small flowers with incurved white sepals and petals, and small labellums marked with yellow in the centre, and streaked with deep crimson; very neat and pretty. Odontoglossum Rossii majus, sepals thickly dotted with light chocolate, petals white with a few dots at the base, labellum white;

a good variety. Sophronitis grandiflora had five good brilliant coloured flowers. Oncidium Rogersii had a spike of large flowers with their characteristic broad yellow labellums. Cymbidium giganteum was bearing a spike of five of its peculiar flowers. Many other plants, notably a specimen Davidsonia pruriens, were in good condition. A vote of thanks was accorded for the group. A very large collection of double Primulas, raised by Mr. R. Gilbert of The Gardens, Burghley, was exhibited. Many of these varieties are particularly good. notably such as White Lady, Marchioness of Exeter, and A. F. Barron among the white and blush varieties, while among the pink forms the best is Lord Beaconsfield. About fifty plants were staged. Messrs. Osbora and Sons, Fulham, have acquired the stock, and will distribute and Sons, Fulham, have acquired the stock, and will distribute these varieties in the spring of 1880. A vote of thanks was accorded to Mr. Gilbert. Messrs. T. Jackson & Son, Kingston, accorded to Mr. Gilbert. Messrs. T. Jackson & Son, Kingston, exhibited two stands of Japanese Chrysanthemums, new varieties. These flowers were in excellent condition, the following being the most noticeable for colour and form:—La Nymphe, La Charmeuse, M. Crousse, Gloire de Toulouse, and Dr. Andiguier. A vote of thanks was accorded. A large and tasteful group of plants was sent from the Society's garden at Chiswick, comprising a number of varieties of Abutilons, intermixed with Ferns and edged with Selaginellas. A collection of single Primulas was also contributed, Selaginellas. A collection of single Primulas was also contributed, comprising some striking varieties, especially among the crimsons. First-class certificates were awarded for P. sinensis Chiswick Red, flower neat and colour bright; and Rubra violacea, a purplish crimson flower with a yellow eye. Messrs. Smith & Larke, florists, Kensington, exhibited several elegant bouquets and wreaths of Chrysanthemums, associated with Adiantums and Bouvardias. A vote of thanks was accorded. Mr. H. Bennett, Manor Farm Nursery, Stapleford, exhibited two Tea Rose plants in pots, Madame de St. Joseph and Alba Rosea, bearing a great number of fruits produced by artificial fertilisation. A vote of thanks was accorded. Mr. J. Roberts, The Gardens, Gunnersbury Park, Acton, was awarded a cultural commendation for a fine specimen of Odontoglossum Alexandræ bearing two spikes of ten and twelve flowers awarded a cultural commendation for a fine specimen of Odonto-glossum Alexandræ bearing two spikes of ten and twelve flowers each. The flowers were large, with a few large chocolate spots on the sepais. Mr. H. Cannell, Swanley, received a vote of thanks for cut flowers of Salvia Bruantii splendens and S. Bethelli in fine condition, also the rich purple S. Hoveyi. Mr. R. Dean of Ealing sent plants of the neat bright Marigold Meteor, also a bright vallow bear in hose Primpres named Buttergun. A vote of bright yellow hose-in-hose Primrose named Buttercup. A vote of thanks was accorded Messrs. Sutton & Sons for a collection of

MESSRS. SUTTON & SONS' PRIZES.

Cyclamens of their improved strain.

The special prizes offered by the Messrs. Sutton & Sons brought together an excellent display of vegetables and extremely close competition. For a collection of twelve distinct kinds, to include competition. For a collection of twelve distinct kinds, to include Suttons' King of the Cauliflowers, Suttons' Improved Reading Onions, Suttons' Improved Dark Red Beet, and Suttons' Student Parsnip, there were nine competitors, all staging excellent collections. The first prize was awarded to Mr. G. Neal, gardener to P. Southby, Esq., Bampton, Oxford, who in addition to the stipulated dishes staged good Excelsior Tomatoes, James' Intermediate Carrots, Snowball Turnips, Cardoons, Suttons' Matchlers Sprouts, International Potatoes, and Ayton Castle Leeks. The second prize was awarded to Mr. J. Muir, gardener to R. M. Talbot, Esq., Margam Park, South Wales; and the third to Mr. W. Igguiden, Orrett Hall. Romford, both pressing closely for the first prize. orrect Hall, Romford, both pressing closely for the first prize, each exhibitor being only one point ahead of the other. Mr. Muir's worst dish was the Celery; his Vick's Criterion Tomatoes, Telegraph Cucumbers, Pomeranian Turnips, and Brussels Sprouts were very good. Mr. Iggulden showed good Tomatoes, Snowflake Potatoes, Celery, Onions, &c. Mr. Wildsmith's collection included remarkably fine Brussels Sprouts.

For twelve tubers of Suttons' Magnum Bonum there were sixteen ror tweeve tubers of Suttons Magnum Bonum there were sixteen entries, all staging good specimens of this popular variety. Mr. J. Fairweather, Halston, Oswestry, was awarded the first prize; and Mr. J. Richardson, Boston, the second. Five exhibitors competed in the class for Sutton's Woodstock Kidney Potato. Mr. Townsend, gardener to P. McKinlay, Esq., Croydon, obtained the premier award; and Mr. H. Harris, gardener to C. J. Eversfield, Esq., Denne Park, Horsham, the second, both staging excellent

P. McKinlay, Esq., exhibited a collection of fifty-seven dishes of Potatoes in his well-known excellent style. Some of the best or rotatoes in his well-known excellent style. Some of the best were Woodstock Kidney. Radstock Beauty, Manhattan, King of the Earlies, Shelbourne, International, Vicar of Laleham, Porter's Excelsior, Blanchard, Magnum Bonum, Trophy, Ashleaf, Snow-flake, Lemon Kidney, and Beckenham Beauty. The latter is a seedling of Mr. McKinlay's, of which he thinks very highly as being in every respect excellent. Messrs. Sutton & Sons, Reading, stagged a capital collection of Potatoes. Sitty-four dishes in all: staged a capital collection of Potatoes, fifty-four dishes in all; staged a capital collection of Potatoes, fifty-four dishes in all; among them Suttons' King, Porter's Excelsior, Advancer, Fenn's Bountiful, Triumph, and Covent Garden Perfection were very noticeable. In addition to these they also staged good heaps of their Magnum Bonum, Woodstock Kidney, and Scotch Champion Potatoes. Messrs. Carter & Co., High Holborn, staged about a hundred dishes of Potatoes, which included all the best varieties

in commerce. Some of the best were the International, Trophy, Main Crop, Breadfruit, Manhattan. They also staged very fine heaps of Carter's Magnum Bonum Potatoes and Scotch Champion, both well-known disease-resisters, and a collection of Turnips and Swedes comprising about sixty-two varieties, many of them excellent examples.

MADRESFIELD COURT GRAPE.

So much has been written lately in the Journal about the fruit of Madresfield Court cracking that I should like to give your readers my experience of this Grape. one young Vine of this variety, this being its fourth season of fruiting. Previous to 1878 the fruit had cracked immediately it began to colour. In July of that year, when the fruit had fairly commenced to colour, the cracking commenced as usual. The weather was very fine, and in consequence no fire heat was employed. While trying to think of something that would prevent the further cracking of the Grapes the idea occurred to me that a higher night temperature, combined with an adequate amount of air, might have the desired effect. I at once lit the fire, and maintained a night temperature of from 65° to 70° till the Grapes were ripe, with the result that in the eight bunches on the Vine there were not more than a dozen cracked berries, and I am satisfied there would not have been any at all had I applied the fire heat earlier. This year the same treatment has been attended with the same results, except that there has been no cracking whatever, although, owing to the dull wet season, it has been much more difficult to keep up the required temperature. The Vine in question has its roots outside. In the same house are Muscat Hamburgh, Black Hamburgh, Muscat of Alexandria, Chasselas Musqué, Lady Downe's, Buckland Sweetwater, Royal Ascot, and Trentham Black, all of which have been highly benefited by the extra heat. A miscellaneous collection of greenhouse Vines are grown in the vinery all the year through, yet the Vines are clean and healthy. I think if growers of Madresfield Court would state under what conditions they grow it, it would be a great help in arriving at the real cause of the cracking.—T. R.

CHRYSANTHEMUM SHOWS.

CHRYSANTHEMUMS in the autumn are as popular as Roses are in summer, and certainly are equally well cultivated. They are also being increasingly grown around London and several large towns, and the shows now being held afford instruction to hundreds of cultivators and gratification to thousands of visitors; the exhibitions therefore merit record, although so far as we have seen the plants and blooms do not equal the high standard of excellence of former years.

WALTON-ON-THAMES.

WALTON-ON-THAMES.

Quite a Chrysanthemum-growing district is that comprising the parishes of Walton, Weybridge, Oatlands, and Hersham—a salubrious and pleasant district too, containing many gentlemen's residences and cherished and well-managed gardens. The Show was this year held at Walton, the new Public Hall being kindly granted for the purpose prior to its formal opening, and probably not zill the next Chrysanthemum show will the structure present such a bright and imposing appearance. The large room was crowded in every part with plants and cut blooms, and several specimens had to be placed in a smaller room adjoining. The cut blooms were arranged en both sides of a table down the centre of the building, the raised central part—the dividing line—being occupied with small plants of Chrysanthemums "suitable for the dinner table." Standard plants were placed down the sides of the Hall with Pompons in frost of them, the ends being staged for dwarf-trained specimens of the large-flowered section. We do not heait tate saying that the general effect of the Exhibition was spoiled trained specimens of the large-flowered section. We do not hesitate saying that the general effect of the Exhibition was spoiled by the miserable "table plants" occupying the prominent position. Had their space been devoted to really useful and well-grown table plants, such as Dracenas, Aralias, Palms, &c., the Hall would have had a much better appearance. Having noticed the little that was good.

little that was bad we will now refer briefly to much that was good. Plants.—The principal prize offered was a silver watch—more useful and valued there than a cup—for six dwarf-trained large-flowered specimens. This prize was well won by Mr. Millican, gardener to H. Cobbett, Eaq., with healthy well-furnished specimens about 2 feet high and about 3 feet in diameter, each plant carrying about fifty blooms. The varieties were Wells' Queen, somewhat resembling Christine; Chevalier Domage, fine; Mrs. Forsyth, Mrs. G. Rundle, Abbé Passaglia, and Beethoven. Mr. Russell, gardener to J. W. Wilson, Eq., Oatlands, was second with immense and well-trained examples 6 feet across, each bearing about a hundred small half-developed flowers; the plants, not the blooms, won this position. Mr. Cornhill was third with plants very fine in foliage and blooms, but the bent stems were too visible to merit higher and blooms, but the bent stems were too visible to merit higher

approval. Mr. Polley, gardener to H. Rogers, Esq., and Mr. Reynolds, gardener to Mrs. Allen, staged collections highly worthy

reynoids, gardener to Mrs. Allen, staged collections nightly worthy of commendation. Mr. Burns, gardener to H. A. Rigg, Esq., won the premier prize for the best single specimen with a fine example of Mrs. Dixon 5 feet across with sixty blooms.

Standards, as they always are at Walton, were remarkably fine, yet not quite equal to the best of last year. Mr. Millican was again in the premier position with Mrs. Dixon, Mrs. G. Rundle, George Glenny, and Prince of Wales, having stems of 3 feet or more, and beautifully formed and not too closely tied heads about 21 feet across. Mr. Plowman gardener to J. J. Wilkes. Esq.. more, and beautifully formed and not too closely tied heads about 2½ feet across. Mr. Plowman, gardener to J. J. Wilkes, Esq., Catlands, staged three splendid plants and a "waster," the lastnamed losing him the first prize. He was second, and Mr. Cornhill third with the finest blooms and foliage of all, but the tying was too close and apparent. With certain little failings all the plants in this class reflected much cultural skill. A special prize offered by the President of the Society (H. Corbett, Esq.) for the best two grafted standards, "the colours to be arranged in circles round the hood," brought out two competitors, both of whom showed very clever handiwork. Mr. Plowman was first with rather round cone-shaped heads, with well-defined concentric colours of yellow, white, pink, and a central white flower. Mr. Millican was second with larger flat heads, the yellow margin being very close but the other rings less perfect. These novelties attracted considerable attention. Pompons were not nearly so good as last year, many flowers not being half expanded. Only

attracted considerable attention. Pompons were not nearly so good as last year, many flowers not being half expanded. Only the specimen plants of Mr. Polley, who was first with Cedo Nulli, and Mr. Millican were really good.

Cut Blooms.—For twenty-four incurved blooms Mr. Reynolds was an easy winner, his stand containing several good, but some small blooms. Mr. Masters, gardener to F. Day, Esq., was second by one point, and Mr. Burns third. The 'best stand of twelve blooms in the Show was the one staged by Mr. Burns, winning Mr. Riggr's special prize. The varieties were Golden Beverley, Fingal, White Venus, Caractacus, Baron Beust, Empress Eugénie, Mrs. Dixon, Hero of Stoke Newington, Mrs. G. Rundle, Lady Hardinge, Faust, and Pink Perfection; they were not large but very chaste. Other good blooms in the classes were Mr. Brunlees, Empress of India, Golden Queen, George Glenny, Mr. Corbay, Prince Alfred, Cherub, Eve, Mr. Hall, Lady Slade, and Gloria Mundi.

Mundi.

Mr. Plowman easily won the first position for twenty-four Japanese blooms, Mr. Burns being second by one point, and Mr. Masters third; and for twelve blooms Mr. Reynolds secured the first position. The best varieties, and attractive they were, were Brit position. The best varieties, and attractive they were, were Fulgore, the finest Japanese bloom in the Show; Diamond, Elaine, Gloire de Toulouse, Bismarck, La Nymphe, a charming pink variety; Garnet, Fair Maid of Guernsey, The Cossack, Fulton, James Salter, Yellow Dragon, Bronze Dragon, Mr. Biggs, Nuit d'Hiver, fine reddish orange; Peter the Great, Ethel, and Gauntlet.

Charming stands of Pompons were exhibited. The conditions

Charming stands of Pompons were exhibited. The condition were three blooms to form a truss, not necessarily on one stemthe best mode of exhibiting Pompons we have yet seen, especially when elevated about 3 inches above the stand, thus showing the when elevated about 8 inches above the stand, thus showing the foliage. Mr. Russell had the first prize with undoubtedly the best flowers, but "squatted" close down on the board. Mr. Masters was second (we should have placed him first), with good flowers and fresh foliage, a charming stand; and Mr. Cornhill third, very attractive. The best varieties were Mr. Astie, White and Rose Trevenna, Sparkler, Mdlle. Marthe, President, Model of Perfection, Durufiet, Aurora, Mrs. Hutt, J. Forsyth, Bob, and of Perfection, Duranet, Aurora, ars. Rutt, J. Forsyth, Boo, and Fanny. Equally attractive were the Anemone Pompons, which the growers of the district excel in producing. Mr. Masters was deservedly first, closely followed, however, by Messrs. Cornhill and Russell. The most attractive flowers were Madame Montels, Marie Stuart, Stella, Miss Nightingale, Antonius, Aglaia, Astrea, Dish Tomics and Collision. Dick Turpin, and Calliope.

Bouquets and floral ornaments were all overcrowded, Mr. Millican's

exhibits being less so than the others, and he was hence the chief prizetaker. The principal prize in the ladies' class was easily won by Mrs. Cobbett with a tasteful arrangement of flowers and

An extra prize was granted to Mr. Sloper, gardener to J. Wooderspoon, Esq., for a small group of plants of Empress of India and Princess of Wales—the finest blooms in the Show; and a and Princess of Wales—the finest blooms in the Show; and a very large and fine collection of dried flowers and Ferns, admirably preserved and mounted on cards by W. Power, Esq., Walton, contributed greatly to the interest of the Exhibition.

Mr. Masters continues to discharge with great efficiency the duties of Secretary, the Committee also working with zeal and in unity; the excellence of the Show and all arrangements connected the service was the contributed of their forethought and

therewith were the gratifying results of their forethought and labour.

BRIXTON AND STREATHAM.

The twentieth annual autumn Exhibition of this vigorous well-managed Society was held on the 18th and 14th inst. in the lecture hall behind the Congregational Church, Brixton Hill, and in the number and excellence of the exhibits it proved very successful, although there was a slight falling off in the Chrysanthemum entries. The schedule enumerated thirty-eight

classes, nearly half the number being devoted to Chrysanthemums, and the remainder provided for the exhibition of miscellaneous plants, fruit, and vegetables, all of which were well represented, the prizes ranging in value from 30s. down to 2s. 6d. Chrysanthemums formed the principal feature of the Show, and many excellent collections were staged both of plants and cut flowers. Among the former the most noteworthy was the collection of six specimen large-flowered varieties from Mr. W. Hall, Secretary to the Society, and gardener to W. Stevens, Esq., Tulse Hill, for which the premier prize in the class was most deservedly awarded. The plants were even in size, the flowers fine and well formed; the varieties—Mrs. Dixon, Mr. George Glenny, Mrs. G. Rundle, and Faust—being in superb condition. Mr. E. Cherry, gardener to Mrs. Slee, Leigham Court Road, was second in the class with very neat plants, Mrs. George Rundle bearing upwards of fifty fine blooms. Mr. J. Howes, gardener to F. Bennett, Esq., Tulse Hill, followed with good plants, but rather small flowers. The Pompon varieties were generally rather sparsely flowered, but the premier collections of six, staged by Mr. J. Howes and Mr. E. Cherry (pyramids), included several good specimens, the varieties Calliope, White Cedo Nulli, Mölle. Marthe, and Brilliant being well represented. These two exhibitors were also placed in the same order with three large-flowered specimens, and Mr. W. Hall obtained the chief prize for the best single specimen of any variety with an extremely well-flowered Midle. Marthe.

The classes for cut blooms were mostly well filled, and the flowers fine. The premier prize for twenty-four incurved blooms was secured by Mr. A. Holmes, gardener to A. B. Hill, Esq., Clapham Park, his collection including remarkably even handsome flowers, the best being Lady Talfourd, Aurea Multiflora, Queen of England, Mrs. Haliburton, Mrs. Dixon, and Empress of India. Mr. J. Holmes, gardener to G. Storey, Esq., Nightingale Lane, staged the best twelve incurved flowers, Prince Alfred, White Venus, Mr. George Glenny, Mrs. Dixon, Prince of Wales, and Bronze Jardin des Plantes being extremely well forned. Mr. G. Ottaway, gardener to F. Hepburn, Esq., Clapham Common, was a close second. The last-named exhibitor was first with six incurved blooms, a very creditable collection in all points, including handsome flowers of St. Patrick, Queen of England, Beverley, Golden Beverley, and Prince Alfred. This was by far the best in the class. The competition in the maiden class of twelve distinct incurved varieties was very good, for six highly meritorious collections were staged. Mr. A. Holmes obtained the chief place of honour with exceedingly handsome flowers. Mr. George Glenny, Mrs. George Bundle, and Mrs. Dixon were superb; Mrs. Haliburton, the Rev. J. Dix, and Venus were also very good. Mr. E. Cherry, and Mr. J. Davy, gardener to Mrs. Drew, Streatham, followed in the order named with well formed but smaller flowers. Of Japanese varieties only two exhibitors appeared—vix., Mr. J. Howes and Mr. W. Horsham, gardener to J. Kempster, Esq., Clapham Common, who were placed second and third respectively with twelve distinct varieties. Those in the premier stand were very good; the varieties—Gloire de Toulouse, James Salter, Bismarck, The Cossaok, Garnet, and Abdul Kadir—being in uncommonly fine condition. Mr. J. Howes exhibited some good Anemone blooms, and was first both with Pompon and large-flowered varieties. There was a good display of miscellaneous plants, including fine-foliage plants, Ferns, Orchids, and Primulas. In

In the classes for fruit Apples and Pears were by far the most numerous, about twenty-four dishes of Pears and thirty-six of Apples being staged, of fair quality generally but rather small. The chief prizes for Apples went to Messrs. Holliday, Sandy, and Cooks; for Pears to Mr. Hall and the two last-named exhibitors. Grapes were not numerous, and the best were the premier three bunches of Black Grapes (Alicante) from Mr. Clarke, gardener to J. Baines, Esq., Nightingale Lane, Balham, which were well finished; and a collection not in competition from Messrs. J. Peed & Sons, Boupell Park, including good bunches of Gros Colman, Gros Guillaume, and Alicante. Vegetables were extremely well shown and some large collections were exhibited, especially in the class for any number of kinds not more than two varieties of each; Mr. J. Swain, gardener to Mrs. Wilson, Lower Tulse Hill, gaining the chief prize with an enormous collection of nearly thirty kinds, many of which were represented by two varieties, all indicating excellent culture; Messrs. Emery and Wright following with good but smaller collections. For a collection of eight varieties Messrs. Holmes, Davy, and Young took honours in the order named with clean well-grown specimens. The arrangement of the exhibits was all that could be desired, and Mr. W. Hall deserves great credit for the satisfactory manner in which the Society's affairs are conducted.

STOKE NEWINGTON.

For more than a quarter of a century has this, the oldest of the metropolitan Chrysanthemum societies, held its annual exhibitions, and the number and merit of the collections at its last meeting on the 18th and 14th inst. prove that the members have by no means relinquished the culture of their favourite flower. That the number and quality of the exhibits should equal those of more favourable years could scarcely be expected, yet the effects of the

season were only apparent in the plants, for the cut blooms were remarkably good in all the classes devoted to them. The principal class for plants was that in which a silver cup value five guineas was offered for the best ten specimens (large-flowered and Pompons) in 11½-inch pots, the second prize being £2 10x, and the third £1 10x. The cup was obtained by Mr. Monk, gardener to H. Head, Esq., Stamford Hill, with well-flowered specimens, of which the following were the best—Prince of Wales, Mrs. George Rundle, Golden George Glenny, Mrs. Hutt, Lord Derby, Mdlle. Mathe, and Venus. Mr. Balsam, Pine Nursery, received the second prize for well-trained and fairly flowered plants. The same exhibitor was first with six large-flowered varieties; but although the plants were good the flowers were rather small, except in Lady Tallound and Barbara, which were the best. Mr. G. Langdon, gardener to Drs. Munro and Adams, exhibited the best collection of four standards in this section, the varieties being Prince of Wales, Mrs. G. Rundle, Golden George Glenny, and Rifleman; Mr. G. Gilbey following with slightly inferior specimens. The Pompon varieties were rather poor generally, but Mr. Marks' premier collection of six were good even plants, including President and Cedo Nulli in fine condition. The first-prize collection of four standards from Mr. Wells, gardener to N. A. Smee, Esq., Woodbury Down, was also good and neat, Antonius, Cedo Nulli, the Lilac Cedo Nulli, and Fanny being well represented. The prize offered for the best single specimen was awarded to Mr. J. Langdon for a well-flowered George Glenny.

well-flowered George Glenny.

The cut blooms were, as we have already intimated, extremely good, the incurved varieties being the most numerous, the Anemone and Japanese varieties being only represented by a few collections, but those were of exceptional merit. In the local nurserymen's and gardeners' class for twenty-four blooms Mr. E. Hammond, gardener to F. Hunt, Esq., York Lodge, Stamford Hill, was placed first with a stand of excellent and even blooms, those of finest form being Queen of England, Prince Alfred, Golden Empress of India, White Venus, White Beverley, Golden Beverley, and Barbara. Mr. H. Butcher's premier twelve were also of considerable merit, Refulgence and Prince Alfred being particularly noticeable for their substance and form.

particularly noticeable for their substance and form.

In the open class for twenty-four blooms, distinct varieties, Mr. J. Clark, Rochampton Lane, was first, and also awarded the fiveguines silver cup for the beet twenty-four blooms in the Show. His collection was an extremely handsome one in every respect, many of the blooms being as near perfection as possible; the varieties Novelty, Alfred Salter, Venus, White Venus, and Beverley were superb. Mr. Monk was a close and good second in this class, and an excellent first with twelve and six blooms, being followed in both the latter classes by Mr. Clark. S. J. Godwin, Beq., of Clapton exhibited a highly meritorious collection of Anemone varieties in the class for twelve distinct varieties, but as the collections contained duplicates he was disqualified, yet it would have been well had the Judges recognised the merit of the exhibit by an extra prize. Only one collection of Japanese varieties was staged—viz., twelve from Mr. W. Monk, for which the premier prize was awarded. This was an exceptionally beautiful stand, the blooms being of extraordinary size, deep clear colours, and good substance. The most striking were Tarantula, Fair Maid of Guernsey, Gloirede Toulouse, James Salter, La Coquotte, and Rlaine. A few classes were provided for miscellaneous plants, but the entries were not very numerous. All the necessary arrangements were well and tastefully carried out by Mr. William Goldsmith, the Secretary. It is, however, to be regretted that the Society is not more liberally supported.

RICHMOND.

The first Chrysanthemum Exhibition of the Richmond Horticultural Society was held on Tuesday and Wednesday last in the assembly rooms of the Castle Hotel, and proved extremely successful in every respect. The number of exhibits was very large, Chrysanthemums, of course, forming the chief feature, but miscellaneous plants, fruits, and vegetables were all well represented. In regard to the Chrysanthemums the Pompon varieties were rather indifferently shown, but several remarkably good specimen incurved varieties were exhibited. Of the flowers also the incurved section was by far the best represented, but the Japanese were shown in fine condition in several collections. The principal class was that devoted to collections of Chrysanthemums in pots, to be arranged in a space not exceeding 50 square feet. Mr. G. King, gardener to R. Few, Esq., Esher, was placed first with a well-arranged group, the quality of the flowers being very good. Mr. J. James, gardener to F. Watson, Esq., Redlees, Isleworth, was second also with a good group; but the flowers, though well formed, were rather small; Mr. J. Barry, gardener to H. C. Slearne, Esq., Radnor House, Twickenham, being third with a well-arranged group. A bronze medal was awarded in this class to Mr. J. D. Kendall, gardener to D. B. Chapman, Esq., Devonshire House, Roehampton, for a good collection, but somewhat irregular; and Mr. Bond, gardener to Mrs. Beckford, Orford House, Ham, obtained a similar award. There were seven entries in this class, the general quality of the exhibits being pretty even. In the class for six trained large-flowered specimens Mr. G. King occurred the premier position with a good collection, but containing one pied the premier position with a good collection, but containing one

or two faulty plants. The best were Mrs. G. Rundle, bearing over sme hundred blooms; and Mr. J. Glenny, of nearly equal excellence.

Mr. G. King exhibited the best single specimen large-flowered variety, a fine example of Mrs. Dixon with over a hundred well-formed flowers. For six trained Pompons Mr. James secured the chief prize with neat, well trained, and well-flowered specimens of Fanny, St. Michael, and Jane Darley among others. Mr. W. Whittaker, gardener to S. Williams, Esq., The Laurels, Putney, was second with rather small irregular plants. Cut blooms were well represented, those noted below being very good. In the class for eighteen distinct incurved varieties Mr. J. C. Holmes, gardener to G. M. Story, Esq., Nightingale Lodge, Balham, was first with very even and regular blooms, Beverley, Venus, Mrs. Dixon, Mrs. Cobay, and Barbara being well represented. Mr. Reynolds, gardener to Mrs. Alfred, St. George's Road, Weybridge, was second with rather irregular flowers. There were four entries, but the other collections were rather poor. The competition in the class for twelve incurved varieties was good, for no less than nine collections were staged. Mr. G. King held the premier position with handsome flowers. Mr. W. R. Strong, gardener to D. Reid, Esq., Virginia Water, followed, but many of his blooms were rather past their best. Mr. J. Plowman, gardener to J. S. Wicks, Rsq., Swiss Cottage, Oatlands Park, was third, and an extra prize was awarded to Mr. J. McPherson, Surbiton. Mr. Kendall was first with twelve Anemone varieties, Queen Margaret and Gluck being well shown. Mr. J. Plowman staged twelve good reflexed flowers and was placed first, Triomphe du Nord being one of his best blooms. In the Japanese varieties Mr. W. Strong was first with a collection of twenty-four extremely good blooms, some of the best being Triomphe du Nord, Elaine, Bouquet Fait, M. Ardene, Red Dragon, and James Salter. Mr. G. King was an excellent second, Gloirede Toulouse, La Nymph, Bismarck, and Fair Maid of Guernsey being good.

second, Gloirede Toulouse, La Nymph, Bismarck, and Fair Maid of Guerasey being good.

In the class for miscellaneous exhibits Mr. F. B. Kinghorn, Sheen Nurseries, Bichmond, obtained a large silver medal for a group of Chrysanthemums, Palms, and fine-foliage plants. Mr. W. Bowell, gardener to Sir H. W. Parker, Stawell House, Richmond, was awarded a silver gilt medal for a similar group; and Mr. Bates, gardener to J. A. Meek, Esq., Twickenham, secured a silver medal for a large group. Messrs. Charles Lee & Son, Hammersmith, staged a fine collection of nearly a hundred blooms, including all the best large-flowered varieties. Messrs. J. Jackson and Son, Kingston, also sent a collection of Chrysanthemum flowers; Messrs. Hooper & Co., Covent Garden, a collection of Chrysanthemum blooms and Cyclamens, and they also were awarded the first prize for six table plants in a class of eighteen competitors.

competitors.

competitors.

Several good fruit collections were staged. Mr. J. Davenport,
Riverside, Twickenham, was first with two good bunches of black
Grapes well finished. Mr. B. Morrell, The Cedars, Richmond,
second with Black Alicantes, also well finished. Apples were
well shown by Mr. G. King, Mr. W. Fanning, The Convent, Roehampton, and Mr. C. Bond. Pears were also numerous, Mr. J.
Hudson, Gunnersbury House, Acton, and Mr. W. Fanning taking
the chief prizes. For a collection of fruits Mr. Bates was first with
excellent Gros Colman and Muscat of Alexandria Grapes, a good
Pine Apple, and Pears. Vegetables were not numerous, but good.
Mr. B. Morrell and Mr. J. Hudson secured the chief prizes.

During the afternoon of the first day a large and fashionable

During the afternoon of the first day a large and fashionable company assembled, thus giving the Society good support in the opening Chrysanthemum Exhibition.

LIVERPOOL

The autumn Show of the Horticultural Society of Liverpool was held in St. George's Hall on the 18th and 19th inst. Chrysanthemums were not so numerous as on previous occasions; yet, considering the disadvantages growers have had to contend with, they were shown in good condition. The first-prize cut blooms were of immense size and very good, but did not possess that high finish possessed by those of last year. Some of the principal growers did not exhibit cut blooms. In the class for six large-flowering varieties Mr. G. Hughes, gardener to R. G. Nolan, Esq., was first with good plants of Prince Alfred (very fine), Mrs. G. Rundle, Barbara, George Glenny, Mrs. Dixon, and Venus. Mr. Hughes was also first in the class for three plants with Mrs. Dixon (fine), Lord Derby, and Mrs. G. Rundle. For a single large-flowering specimen Mr. Whitfield gardener to Mr. Crosfield, was first with a fine plant of George Glenny. In the class for six Pompons Mr. Whitfield was first with well-grown specimens. Mr. Finnigan was first for three plants, also for a single specimen with Pompons Mr. Whitfield was first with well-grown specimens. Mr. Finnigan was first for three plants, also for a single specimen with White Cedo Nulli. In the class for a standard Chrysanthemum Mr. Green was first, and Mr. Rose, gardener to J. C. Read, Esq., second. The six specimens shown by Mr. Tunnington not for competition were really grand, most profusely covered with fine and even-sized blooms, and the foliage good. They were by far the finest standards in the Show. The varieties were Mrs. George Rundle, George Glenny, and Mrs. Dixon shown in pairs, and certainly these plants reflected much credit on the cultivator.

In the class for cut blooms twelve varieties J. W. Cropper, Esq., Dingle Bank, was first. The blooms were very large, and comprised

Empress of India, Prince Alfred, Bronze Jardin des Plantes, Beauty, Novelty (fine), Queen of England, Prince of Wales, Alfred Salter, Lady St. Clair, Jardin des Plantes, and John Salter. Mr. Wilson, lady St. Ciair, Jardin des Plantes, and John Salter. Mr. Wilson, gardener to J. E. Reynolds, Esq., was second with much smaller blooms but neat; third Mr. J. Peers, gardener to R. Raynor, Esq. In the class for eighteen out blooms Mr. Cropper was again first with very fine blooms of Plenipo, Novelty, John Salter, Empress of India, Bronze Jardin des Plantes, Prince of Wales, Prince Alfred, Queen of England, Mr. Cobay, Golden Empress of India, Lady St. Clair, Alfred Salter, Little Pet, Jardin des Plantes, and Sir Stafford Corey. Mr. Messes gardener to C. W. Newman, Esq. was Lady St. Clair, Airred Saiter, Little Fet, Jardin des Flances, and Sir Stafford Carey. Mr. Mease, gardener to C. W. Newman, Esq., was second with fine blooms, yet compact and of good depth of petal, and contained that solidity requisite for good flowers. Miscellaneous plants and fruit were also exhibited, the collections being generally very good; but the pressure on our columns precludes a detailed report of this section of a very good Show.

BOROUGH OF HACKNEY.

This Society held its annual Chrysanthemum Exhibition in the Royal Aquarium, Westminstar, numerous and good collections of both plants and flowers being exhibited; but, as has been the rule this season, the general quality of the flowers was above that of the plants, although there were several exceptionally good collections of specimen large-flowered varieties. Our notes are necessarily brief, for the awards of the Judges were only made a few hours before we went to press, but the prizetakers in some of the principal classes are given below. No less than eight silver cups were offered in different classes, and the competition was generally close. The system adopted of affixing the awards to the winning collections was unfortunately one of the worst we have witnessed this year.

have witnessed this year.

Plants were not quite so numerous as usual, but of fair quality. The silver cup offered by the Boyal Aquarium Society for the best group of Chrysanthemums was obtained by Mesars. Dixon & Co., Hackney, the group including good plants but thickly placed. Mr. J. Balaam, Vine Nursery, Clapton, was placed second with a rather poor group. The cup of similar value for six standards was obtained by Mr. W. Brett, The Crammers, Mitcham, with extremely fine specimens, well trained and flowered. The Cossack and Elaine were exceptionally even and beautiful. There were several other collections, but owing to the delay in affixing the prize cards we could not accertain the awards.

In the cut flowers one of the principal open classes was that for

were exceptionally even and beautiful. There were several other collections, but owing to the delay in affixing the prize cards we could not ascertain the awards.

In the cut flowers one of the principal open classes was that for twenty-four incurved blooms, the first prize being a silver cup valued at £5. There were seven competitives, all staging good even collections; Barbara, Prince of Wales, White Beverley, and Mrs. Dixon being well represented in all. C. Lunderoon, Eaq., Willesden, was first with handsome bloems. Mr. G. Fanning, Roehampton Lane, was a good second. Of the six collections of twenty-four incurved varieties the best was that from Mr. G. Langdon, gardener to Drs. Munro and Adam, Clapton, who was placed first with a handsome collection of flowers, Golden George Glenny, Venus, Barbara, Prince Alfred, and Refulgence being remarkably good. The second (Mr. C. Gattrell, Hackney) and third (Mr. J. Williams, Stoke Newington) collections were also of more than ordinary merit. For twelve incurved varieties Mr. G. Langdon was first; Mr. Gilby, gardener to B. Booth, Esq., Clapton, was second; and Mr. Gattrell third. All good; nine entries. Classes 13, 14, and 15—for twenty-four, twelve, and six incurved blooms—were confined to amateurs residing in the boroughs of Hackney and Finsbury. The flowers were rather small, but well formed. The principal prizes went to Mr. G. Godwin, Clapton; Mr. H. Vinny, Stoke Newington; and Mr. J. Broughton, Stoke Newington. In the class for twelve incurved varieties there were nine entries, the blooms generally being well formed. Mr. C. Gibson, The Gardens, Morden Park, Mitcham, being first; Mr. E. Bury, Roehampton, second; and Mr. R. Whitely, Southwark, third. There was only one entry of twelve large Anemone blooms from Mr. E. Bury; a very good one, including Princess Louise, Prince of Anemones, and Gluck in fine form. Four collections of twelve Pompon Anemones appeared, the chief prize going to Mr. W. Brett, The Gardens, Cranmers, Mitcham, for very neat flowers. Seven good c

dried Grasses; and Mr. H. Cannell, Swanley, who had a collection of Zobal Pelargonium flowers.

marked character, and unquestionably surpass their parents in decorative value, and in this respect are well deserving of attention. The influence of amona is clearly evident in the AZALEA MRS. CARMICHAEL.

THIS remarkably handsome and useful Assless is one of the distinct and attractive varieties which resulted from Mr. Carmichael's successful experiments in intercrossing Flag of Truce, Biells, and amouns. All the forms thus obtained have a very difference of amouns is clearly evident in the foliage and general habit, there being, however, a slight solven upon the species in vigour and freedom of growth; but we think that the flowers, although possessing certain amouns characters, approach somewhat more closely to the indice varieties. The combination of a compact yet vigorous habit with freedom and brilliancy of flowers render the plants both besserved.

medium size and produced in large compact globular heads, the colour being of an intense magenta-crimson tinge not easy to describe. The plants are admirably adapted for decorative purposes throughout winter and early spring, and if slightly assisted by heat may be had in excellent condition from the present month onwards. The neat form and bright colour of the flowers also render them of considerable value for bouquets, &c. The merit of the variety figured was recognised some time since at one of the Royal Botanic Society's exhibitions by the award of a first-class certificate. Mr. B. S. Williams of Upper Holloway (to whom we are indebted for the annexed flowered here this autumn but has ripened its cool, a posity

tiful and useful. As is well seen in the cut, the flowers are of | engraving), possesses the stock of these Carmichael varieties, about six or seven of which have been sent out and certificated Another very fine variety in this section is Duke of Conneight for which Mr. B. S. Williams received a first-class certificate at the Royal Horticultural Society's meeting on March 27th of this year. It is likely to become a great favourite owing to its very brilliant colour—bright crimson scarlet.
